Dr. Wilson then dealt with the development of premature arterio-sclerosis in the diabetic; coma, which had been the chief cause of diabetic deaths before the introduction of insulin, was being replaced in that rôle by arterio-sclerosis. It therefore became important to inquire why the diabetic was specially prone to arterio-sclerosis. He thought there was some evidence that the excessive fat in the diet of the diabetic was an important factor, by predisposing to excess of cholesterol in the blood. If that were true it was necessary to keep the fat in the diet within limits, and in doing this insulin was most helpful by keeping the carbohydrate element high, with a corresponding fall in the amount of fat. The diseased heart muscle of many middle-aged and elderly diabetics seemed to demand a higher level of sugar in the blood than normal, if it was to be properly nourished; a practical application of this demand was to be found in the caution required in any attempt to lower a high blood-sugar in a diabetic with diseased heart muscle by insulin. It was easy to provoke an attack of angina pectoris by the administration of insulin, and if insulin were used with patients liable to such attacks it was necessary to use a high carbohydrate diet. Dr. Wilson had been impressed with the importance of equal caution in the use of insulin in diabetics with retinitis. He then discussed diabetes in children, and particularly in children whose glucose tolerance curves were not typically diabetic, and yet were not normal. Such cases should be watched; he had seen two such children develop typical diabetic curves.

He felt that the education of the diabetic patient, upon which ultimate success largely depended, did not receive sufficient attention. The diabetic should learn his diet and the value of each element in it. It was possible to simplify this to a great extent for him. He should learn, too, how to test his urine for sugar, and how to avoid coma and gangrene. Many diabetic patients were seen in the out-patient department without inspection being made of their feet. Coma was largely a preventable accident. Nobody would think of driving a car without an insurance against third party risks; it was far more important for the diabetic to master the technique of insulin administration. He might not need it for the present, but the day would probably come when an infection would render it necessary, and his knowledge gained at leisure might then save his life. Exercise was very helpful; it was the tissues and not the kidneys that removed the excess of sugar from the blood, yet it was a common practice in hospitals to see diabetic patients confined to bed for weeks without any provision for exercise. The attempts made in recent years to persuade the practitioner that diabetes was a simple affair were very well in their way, but we had to realise that in few medical diseases could the doctor be of as much assistance to his patients as in diabetes, and that if he was to render this assistance he must himself master the broad principles on which the diabetic diet of to-day rests, and the details which make it practicable to transfer that knowledge to the patient.

CHILDREN'S HOSPITAL, BELGRADE.—Through the Save the Children Fund (28, Gordon-street, London, W.C. 1) an appeal is being made for this hospital by the members of the British Legion who have just returned from the annual congress of the Inter-Allied Federation of Ex-Service Men at Belgrade. They call to remembrance Dr. Katherine Macphail's work in creating a modern, well-equipped hospital of 50 beds and an out-patient department through which more than 100,000 children have passed during the last ten years. The infant mortality in Serbia is "appallingly high"—one in three. The hospital trains Serbian girls as nurses under the supervision of a British matron. It is partly maintained by the Jugo-Slavian Government, but a further £2000 has to be found, two-thirds of which has to be collected by Dr. Macphail. This is the only hospital exclusively for children in the country.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Association of Insurance Committees.

AT the annual meeting in Ayr of the Scottish Association of Insurance Committees Provost Irvine, of Coatbridge, the President, commented on the need for specialist and consultant services, not only as an advance towards a complete and satisfactory medical service for the insured population, but also as a sound financial proposition, saving its cost by reducing the amount paid out in sickness benefits, and ultimately enabling approved societies to make substantial contributions or even to meet the whole expenditure upon these services. He also criticised the hiatus now existing between the statutory age for leaving school and the statutory age for entering into national insurance. From the period of infancy till the age of leaving school health services were continuously available, at considerable cost it is true, but with satisfactory results. Yet, for those between the ages of 14 and 16 years, no provision for health service was made. This serious anomaly stood self-condemned. Provost Irvine is a well-known pioneer in Scottish public health work, and understands both sides of the question.

Drugs for Insured Persons.

One of the best parts of the Scottish system of National Health Insurance is the central checking bureau at Glasgow, through which all prescriptions pass, and are there subjected to technical criticism and pricing. It was stated at the Ayr meeting that the number of prescription forms handled last year on behalf of the 54 insurance committees in Scotland—namely, 2,055,737—was a decrease of 93,000 on 1927, and 104,000 less than the record year of 1926. The value of the prescription forms, exclusive of the cost of insulin, was £147,328, a decrease of £4410 on 1927. The average price per form at 13·31*d.* was very slightly above the average for the previous year, 13·24*d.* The tariff price of 100 units of insulin has been reduced by successive stages from £1 6*s.* 8*d.* to 2*s.* 7*d.*, and it was rumoured at the meeting that a German firm had offered to supply London hospitals for a year with insulin at 1*s.* for 100 units. The bureau has now handled 32½ million prescription forms at a total cost of 1¾ million pounds. The vexed questions of who should foot the bill for drugs for insured persons while in hospital led to the passing, by a large majority, of the following motion: "That the cost of drugs, including insulin, supplied to insured persons under treatment in voluntary institutions should be a charge against the drug fund of the insurance committee, instead of having to be met from the funds of the voluntary institution." The original Insurance Commission and the later Board of Health never saw their way to accept this proposition; it remains to be seen whether the insurance committees will be more successful with the new health department.

Working Out the 1929 Act.

Mr. John Jeffrey, Secretary of the Department of Health, gave the meeting his views on the effect that the Local Government (Scotland) Act, 1929, will have on the work of insurance committees. Endless complications would, he said, ensue unless steps were taken to achieve harmony in the relationship between the general practitioner and the specialist in hospital and dispensary services. When a patient was referred to a hospital or dispensary the very fullest medical history sheet should accompany him, and just as surely when he returned to the care of his insurance practitioner the fullest information regarding his condition and treatment should be supplied by the specialist in whose charge he had been. Mr. Jeffrey said he had been advised that 20 to 25 per cent. of insured persons receiving treatment from their panel doctors were in need of specialist advice. The health insurance funds had failed to meet that requirement, but under the hospital organisation of the 1929 Act it should be possible to bring to the aid of the insured person all the requirements of equipment and specialist services, while retaining the traditions of unfettered work. He went on to speak of the advantage to the general health of the community if some system could be devised whereby each insurance committee should supply to the local authority statistical information on the nature and extent of sickness among insured persons in the area. At present the local authority had no knowledge of the prevalence of ordinary sickness, or of the nature and causes of that sickness, or whether any action on its part could prevent or reduce such sickness. Now that the insurance committee and the public health authority were to coöperate the gap could be filled up.

Dr. Kinloch envisaged the development of a local authority hospital service with everything in the nature of elaborate equipment and specialist skill available for the insured population through their panel practitioners. This provision would in time release insurance committees from most of their present commitments on additional benefits, and enable them to plan a comprehensive extension of the insurance medical service embracing the dependents of insured persons not covered by the local authority service.

A Crematorium for Edinburgh.

Over 20 years ago a movement was started to provide a crematorium for Edinburgh, and a company formed in July, 1928, under the chairmanship of Lord Salvesen, lately acquired from the corporation two and a half acres of the Easter Warriston Estate, at a cost of £3000, on condition that dividends paid on the share capital should not at any time exceed 6 per cent. per annum. The late Sir Robert Lorimer was the architect, and the original mansion house has been adapted partly to form the crematorium and partly to form a chapel. The whole cost of buildings, roads, grounds, and furnishings is expected to be about £10,000. Hitherto all Scottish cremation has been done in the Glasgow Crematorium.

A New Hospital for Cripple Children.

On Oct. 1st the Duchess of York laid the foundation-stone of the new Edinburgh Hospital for Cripple Children. Sir David Wallace, chairman of the committee, said that sufficient money had been raised to justify the commencement of the building. The site extended to 14 acres, and its large size would permit of the children being educated in the open air. Some would be trained in workshops so arranged that the patients could work in the open air and the sunlight. It was proposed, said Sir David, that major and minor clinics should be formed throughout the various counties under the scheme, and at the earliest possible time children treated in the hospital would be sent to those clinics, after which the necessary treatment could be carried on in their homes under careful supervision, and in close relation with the central staff of the hospital. I understand that of the sum of £70,000 aimed at, some £55,000 has already been raised.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Dispensary Salaries in Co. Mayo.

FOR many years the salaries of poor-law medical officers in County Mayo have been markedly lower than those of any other county in the Irish Free State. Not only were the salaries inadequate, but they were very uneven, so that medical officers in certain districts were drawing only half the pay of their neighbours doing approximately equal work. Many appeals had been made to the county board of health to establish an equable scale of salaries for the whole county, but the appeals were fruitless. Attempts by the Department of Local Government and Public Health to persuade the Board of Health to move were equally useless. At length, however, the Minister has found it necessary himself to intervene, and by sealed order he has fixed the salaries of the several medical officers in the county. The new salaries are based on a scale of £200 a year, rising by annual increments of £5 a year to a maximum of £300. Each medical officer gets credit for all his pensionable service under the board. The immediate increase of salary to the several medical officers varies from nil to £160 a year, and averages £57 a year. The number of dispensary medical officers in the county is 30, and the immediate increase in salaries amounts to £1706 10*s*. This is the first occasion on which a whole scale of salaries has been established by sealed order over the heads of the local authority, and it is important for medical officers elsewhere that the precedent has been established.

Antivaccination and its Costs.

County Wexford has been the one county in Ireland in which the antivaccinationist movement gained any foothold, and for some years past its inhabitants have been very inadequately vaccinated. Within the past year or two, however, the Department of Local Government and Public Health determined to enforce the laws concerning vaccination, and legal measures were taken to compel the local authorities to fulfil their statutory duties. Reluctantly enough they are instituting prosecutions of those who neglect to bring their children for vaccination, and they find that each prosecution costs them nearly £1. There are said to be some 18,000 defaulters in the county, so that the total cost may prove to be considerable. At its last meeting the Board of Health made the naïve request to the Minister for Local Government and Public Health to give them a grant from public funds to enable them to enforce the laws. Having neglected its duty for years, the board finds the expense of fulfilling its accumulated obligations too heavy, and it suggests that the general taxpayer should come to its aid.

MEDICINE AND THE LAW.

The Law of Murder: Confession Without Corpse.

IT was not till 1926 that (as one result of the Coroners (Amendment) Act) it was possible to hold an inquest in the absence of a dead body. The possibility or impossibility of prosecuting a charge of murder without the proved existence of a corpse was discussed afresh last month. A man walked into a London police station and gave himself up as a self-confessed murderer. He said that one night in August last he met a woman named Rose while he was under the influence of drink, quarrelled with her, and flung her over the parapet of Waterloo Bridge, at an exact spot which he described. When he was charged before Sir Chartres Biron, the police informed the court that no body had been found, no woman named Rose was missing, and the man had not been seen in company with any woman that night, but had been seen alone in a public-house. They added that to throw a body over the bridge meant lifting the body up some seven feet, and required great strength, and that no screams were heard, either by a constable on duty 50 yards off or by a night-watchman slightly farther away. The magistrate, not wholly convinced by the confession, dismissed the charge. This course leaves the police free to prosecute afresh if new evidence becomes available. A confession, undoubtedly, can be adequate evidence, provided that it is clear and unequivocal. So said the Court of Criminal Appeal 20 years ago, in a case where a mother confessed that she had burnt her baby's body. But the police, who receive many strange confessions when any criminal mystery becomes a public sensation, are aware that abnormal mental states may prompt such statements, and they examine them with a care which sometimes becomes scepticism. English criminal procedure is reluctant to see an accused person self-convicted. This tradition or instinct militates against the acceptance of a well-known police magistrate's recent suggestion that an accused person should be not only a competent but also a compellable witness. And English judges know the dangers of finding murder charges to be established when no dead body has been discovered. Coke, in his Institutes, gives a quaint anecdote of a case where the murderee returned after the supposed murderer had been hanged. An orphan girl was brought up by her uncle, and, one day, when he was correcting her for some fault in the method usual at the time, she was heard to cry out "Oh! good uncle, kill me not." Next day she was not to be found, and as the uncle stood to inherit property at her death, he was put into jail on suspicion of murder. Released on bail to give him a chance to produce his niece, he stupidly produced another girl of the same size, dressed in his niece's clothes. The trick was discovered, and he was hanged for murder, but anon the niece appeared, proved her identity, and successfully claimed her estate. She had run away into the next county instead of going to school the morning after her uncle beat her, and she had been kindly entertained by strangers who took pity on her. Coke tells his tale to point the double moral that judges must not be too hasty in assumptions in murder trials, and that innocent persons must not play silly tricks as the uncle did. A famous case of the same kind, reported in the State Trials, is that of the Perrys. Two brothers and their mother were found guilty of murder and hanged, and in a few years' time the supposed victim reappeared. There is a dictum of Sir Matthew Hale that he would never convict of murder unless either a dead body is found or the fact of the murder is proved. The latter alternative occurs in murders at sea, where the body is thrown overboard. The leading case is R. *v.* Hindmarsh (1792), where a seaman murdered his captain. No body could be produced, but there was sufficient evidence of the accused's declared intention, and of the actual struggle in which the captain was seen to be pitched into the sea.

A Dangerous Rat Poison.

The death of an Alton farmer from cyanide poisoning, as a result of blowing a rat poison powder down a rat hole in a closed shed by means of a bellows, has been noted in several daily papers. It is not quite clear what was the exact nature of the powder in question, although its name "cyanogas" would suggest to anyone acquainted with drugs or elementary chemistry that it was highly poisonous. A man may, however, be a good farmer without much knowledge of the Pharmacopœia, and such a man has a right to expect that poisons should not be put in his hands without full instruction for use. The coroner in this case described the directions as, in his opinion, carelessly drawn. The technical adviser of the manufacturers said it was dangerous to use the powder with a bellows or, indeed, in an unventilated shed; he considered that the instructions were strict in regard to ventilation. It is, no doubt, very difficult for a technologist to realise the extraordinary risks which people unused to handling dangerous materials will take. For this reason such rat poisons as barium carbonate, squill mixtures, and the like should suffice the general public, and the use of more deadly preparations be confined to professed vermin killers. The use of cyanides was prohibited in the city of Paris by an edict of the police last year, and they should only be supplied with the most explicit instructions for their use. Poisonous gases are more easily evolved than controlled or dissipated, and it is dangerous to disperse poisonous powders by blowing.

A HOSPITAL BURNED DOWN.—Aberdare and District General Hospital was totally burned on Sept. 27th, when two firemen lost their lives and a third was seriously injured. There were over 80 patients in the wards but they were all safely removed, at great risk to the matron and nurses. The damage is estimated at £20,000.

MALIGNANT TUMOURS IN FOWLS.

To the Editor of THE LANCET.

SIR,—The explanation offered in your last issue (p. 697) by Dr. A. M. Begg and Dr. W. Cramer for the appearance of Rous sarcomata in fowls which they had injected with extracts of fowl pancreas and mouse carcinoma—namely, that sufficient traces of the Rous agent were retained in a mortar after the latter had been washed in running water—may satisfy them, but it does not apply to the experiment of ours which they cite. Our material was merely minced with sterile scissors in a sterile Petri dish, and was not ground in a mortar, nor had any Rous material been in use at or about the time. Further, the bird that developed the tumour was one in a series of 23 inoculated with the same tissue, and none of the series came in contact with fowls bearing Rous tumours.

Perhaps I may be allowed to add that our tumour was at first histologically distinguishable from the ordinary Rous sarcoma, that one at least of Dr. Murphy's tumours produced by testicular extract was quite distinct, and that the tumour produced by Dr. Maisin through the action of ionium nitrate on grafted embryo tissue was again different.

I am, Sir, yours faithfully,
ARCHIBALD LEITCH.

Cancer Hospital Research Institute, London, S.W.,

INTERPRETATION OF THE WASSERMANN REACTION.

To the Editor of THE LANCET.

SIR,—As one who has long contributed to your columns on the subject of the interpretation of the Wassermann reaction, I venture to lay before your readers a few criticisms of Dr. T. E. Osmond's article on this subject appearing in your issue of Sept. 28th (p. 677). I begin by quoting three sentences from an admirable leading article in THE LANCET of March 2nd (p. 453):

> 1. "Even when the test is made in laboratories where routine procedures are most carefully standardised under the direct personal supervision of an expert, the reaction given by a patient not actually undergoing treatment may vary in an unaccountable manner . . ."
>
> 2. "Two years ago a series of comparative tests were performed by pathologists working in different laboratories, all of whom used substantially the same technique. The results differed by as much as 25 per cent."
>
> 3. "It is true that the exact relation of the degree of strength of the Wassermann positive readings to the severity of infection is unknown."

In the same issue of THE LANCET appeared an article by myself in which I said:—

> "During the last 20 years I have reiterated my opinion that while the Wassermann reaction was a good servant it was a bad master, that the test was clearly not specific, that there appeared no logical reasons why other similar chronic infections should not produce a like reaction, and that, therefore, no one should be dogmatically branded as a syphilitic on the evidence of a positive Wassermann reaction unsupported by any other historical, clinical, or pathological evidence."

The League of Nations has recently published the Report of the 1928 Copenhagen Conference on the "Sero-diagnosis of Syphilis." This conference was attended by pathologists of 16 nations, and the resolutions which they passed seem to suggest that Dr. Osmond's dogmatic assertion in the first sentence of his article is not corroborated by world opinion. Dr. Osmond says:—

> "Provided that a [illegible] is employed and the test carried out by a c[illegible]ist a positive Wassermann reaction (++ or +) means that the patient is infected with syphilis—recent or remote. The only exception to this rule is 'yaws.'"

It is true that this initial dogma is a little hedged against in some later sentences, such as "no case should be labelled syphilis on the strength of a single isolated positive Wassermann," "the fluctuating Wassermann—on one occasion positive and another negative—is now recognised by most workers." and in his concluding summary "a positive result nearly always means syphilis, if there is a doubt it should be repeated and confirmed." In view, however, of his initial dogma carefully placed so as to catch the eye of those who will not read the whole article, I cannot but feel that the subsequent less dogmatic remarks were made, not because Dr. Osmond doubted the truth of the dogma contained in his opening sentence, but because he had read the Copenhagen Report.

This report contains eight resolutions passed by the conference, from which I will make quotations from four; they are:—

> 1. "The Conference is of the opinion that the best of them (flocculation tests) may be regarded as equal in value to the best of those which depend on fixation of complement (Bordet Wassermann)."
>
> 2. "The Conference recommends that in order to secure the most reliable information to the clinician, at least two different sero-diagnostic methods should be used."
>
> 3. "The Conference recommends that the serologist should check the accuracy of his tests by regular and very frequent reference to clinical data."
>
> 5. "The Conference wishes to reiterate with particular emphasis: (3) that except in the case of a few well-defined pathological conditions, syphilis is indicated with a degree of probability, which closely approaches certainty, when several tests performed according to different methods give a positive result."

These resolutions contain opinions widely differing from, and in my opinion much more in accordance with facts than, that expressed in the opening sentence of Dr. Osmond's article which I have quoted, and which I believe to be incorrect and misleading.

I am, Sir, yours faithfully,
Harley-street, W., Oct. 2nd, 1929. H. WANSEY BAYLY.

CURES AND PREVENTION.

To the Editor of THE LANCET.

SIR,—I cannot allow the address of Sir Farquhar Buzzard to the students of the University of Birmingham to pass without the strongest protest. It is a frank confession of the failure of the accepted methods of treatment of disease that is mainly of lesions produced by microbes in the human body, and it is this incapacity of medicine to produce efficient intravital germicides that has led to this confession of failure of Sir Farquhar Buzzard and the public criticism of our profession which he acknowledges to be just. For there is only one efficient intravital germicide in the Pharmacopœia, and that is antidiphtheritic serum.

Is it not true that all our efforts in the teaching of the practice of medicine are concentrated on enabling the student to discover the tissues diseased, and to relieve the symptoms produced and most vitally to give that disease a name, with which the patient will be satisfied? We do not teach the student how to kill the microbes causing that disease and thus "cure" the disease. That is what our patients demand, and quite properly demand, and if we, as physicians, cannot do it, they will turn to those who say they can, as patients suffering from orthopædic troubles have turned to the unqualified, because qualified surgery was reputed not to be able to accomplish the very properly demanded cure. An accurately scientific method of preventing and aborting common cold is available, and we are in a position to say now that no catarrhal infection need ever become chronic. Anterior poliomyelitis can be so treated in the acute phases that the patient can be restored with little or no damage to his musculature. The causative microbes can always be found.

I am sure Sir Farquhar will think that such a disease as disseminated sclerosis is an absolutely incurable condition. I can assure him that it is not so, that the cause can always be found, the infection of the spinal cord arrested, and the patient restored to his normal avocations. And so with practically all other microbial diseases that are now considered incurable. I expect these assertions of mine to be received with the usual derision, but I warn authoritative members of my profession that the writing is on the wall, and that they had better turn to the study of the production of "cures" if they wish us to survive as a profession.

I am, Sir, yours faithfully,
W. M. CROFTON.

University College, Dublin, Oct. 7th, 1929.

HARMINE OR HYOSCINE FOR ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 28th (p. 647) Dr. T. R. Hill and Dr. C. Worster-Drought discuss the treatment of chronic encephalitis with harmine and contrast their results with those reported by Rustige in Germany. Although Rustige does not claim that his findings bring harmine within the range of practical therapeutics, yet the discrepancy between his observations and the more recent ones remains to be accounted for. May it not rest upon the form and duration of the previous treatment that these different groups had undergone? The cases reported in your columns had been treated with hyoscine hydrobromide gr. 1/100 hypodermically three times daily, for how long is not stated. Rustige's patients had been treated with "scopolamine-atropine," how much or how long again we are not told. Hyoscine, I think, has a greater psychical effect than atropine, habit is more readily established, and in some cases it seems that its influence is very largely subjective. Under the circumstances and in default of fuller information it seems reasonable to suggest that the patients of Hill and Worster-Drought had become more dependent on the treatment in force before the change than were those of Rustige. The insistence of the encephalitic who is under treatment by hyoscine on his need for hyoscine seems to offer a serious obstacle to successful results with any alternative. He is acutely aware of all his objective manifestations, and if he believes that hyoscine keeps them in abeyance he may quite conceivably recall every one when his hyoscine is withdrawn, for his memory of detail is far better than that of the general run of patients. That there should be, as Drs. Hill and Worster-Drought describe, a rapid improvement on resumption of hyoscine does not negative this suggestion.

I am, Sir, yours faithfully,
Dundee, Oct. 3rd, 1929. J. M. STALKER.

LIVER TREATMENT IN SUBACUTE COMBINED DEGENERATION OF THE CORD.

To the Editor of THE LANCET.

SIR,—In his review of the nervous and mental aspects of pernicious anæmia (THE LANCET, Sept. 28th, p. 643), Dr. Douglas McAlpine criticises an article by Dr. M. M. Suzman and myself on subacute combined degeneration of the cord. While in agreement with him that the type with pyramidal involvement and little anæmia is more resistant to liver treatment, we have found that many of the spastic cases with marked anæmia have done very well indeed. We have re-examined our cases after an average period of 16·6 months' liver treatment, and in two further cases, making five in all, extensor plantar responses have become flexor in type. We have had no occasion to modify our opinions as to the good results obtained in subacute combined degeneration with sufficient liver dosage, provided that there is no urinary or dental sepsis. It is essential, however, that the cases be followed up for a sufficient length of time, as the effects on the nervous system may not be apparent for months after the anæmia has disappeared. It must be emphasised also that the optimum amount of liver required for improvement in the nervous phenomena is considerably in excess of the minimum amount required to combat the anæmia.

Dr. McAlpine wishes to draw conclusions with regard to the degree of anæmia in our non-improved cases. A careful study of the article will render it obvious that the reasons for failure to improve in these were, not the absence of a marked anæmia, but the inadequate dosage of liver, and in some the presence of septic complications. We have not found the administration of hydrochloric acid to affect the rate of improvement; the majority of our improved cases had none. Its use, however, has been found beneficial at times for gastric symptoms.

In conclusion, may I point out an error on p. 646 in quoting our report. The sentence (col. 2, line 34) should read, "of the 31 cases that had no liver, 28 died within an average period of 14·6 months (not 4·6 months) from the onset of the disease."

I am, Sir, yours faithfully,
C. C. UNGLEY, M.D., M.R.C.P.

Newcastle-on-Tyne, Oct. 4th, 1929.

ABDOMINAL TENDERNESS AND UNNECESSARY OPERATIONS.

To the Editor of THE LANCET.

SIR,—In the note on this subject, on p. 740 of your last issue, your occasional correspondent in the United States describes Dr. J. B. Carnett's teaching as "certainly heretical." I am amazed at this late date to find such a statement in print. I have held these views and used the same tests as Dr. Carnett for some years, and find that the condition he describes is very prevalent. Because tender nerve segments occur in the abdomen and chest the profession, as a whole, have accepted the work of Head and Mackenzie as interpreting that the disturbance is due to disease in one or other organs innervated by that spinal segment. If, however, the pains are complained of in an extremity, then the diagnosis is neuralgia or neuritis!

I am, Sir, yours faithfully,
R. CHALMERS, M.D., F.R.C.S.E.

Darlington, Oct. 4th, 1929.

TRELOAR CRIPPLES' HOSPITAL.—The work of replacing the wooden wards at Alton has now begun. There are to be five ward blocks of 60 beds each, and each ward unit provides for two wards of 24 beds each, two wards of four beds each, and four cubicles. They will face south to a wide terrace nearly 1000 feet long, and the large wards will have folding doors to enable them to be used as open-air wards opening upon a verandah glazed with Vita-glass. The administrative block will be on the north side.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The opening lecture of a series on Common Complaints will be delivered by Dr. F. G. Chandler on Monday, Oct. 14th. Particulars of this and other lectures during the coming week will be found in our Medical Diary Sixteen lectures intended for candidates for the M.R.C.P examination will be held at 8.30 P.M. on Tuesdays and Fridays, from Oct. 15th to Dec. 6th, at the rooms of the Medical Society of London. From Oct. 14th to 26th a morning course will be given at the Hospital for Sick Children, and between the same dates there will be a course in gynæcology at the Chelsea Hospital. An intensive course will be held at the Central London Throat, Nose and Ear Hospital from Oct. 14th to Nov. 2nd; and an intensive course in medicine, surgery, and the specialties at the Metropolitan Hospital from Oct. 21st to Nov. 2nd. The latter course is intended to appeal to practitioners. Further information about special and general courses may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W.1.

Obituary.

THOMAS JENNER VERRALL, M.R.C.S. Eng., LL.D. Aberd.;

LATE CHAIRMAN OF REPRESENTATIVE BODY, BRITISH MEDICAL ASSOCIATION.

We regret to announce the death on Oct. 4th of Sir Jenner Verrall, one of the best-known workers in the country for the advancement of the whole medical profession.

Thomas Jenner Verrall was born in 1852 at Brighton, the second son of Henry Verrall, a well-known Brighton solicitor, his elder brother being Arthur Woollgar Verrall, the famous Cambridge Greek scholar. Jenner Verrall was educated at Marlborough, and on leaving school in 1869 proceeded to St. Bartholomew's Hospital, whence he duly qualified in 1876. He had previously gone through a part of his medical training at the Sussex County Hospital, and shortly after qualification was elected surgeon to that institution, a post which he held until 1912, when he was elected consulting surgeon. As a practitioner he won from the start the esteem and confidence of a large circle of patients and friends, and when, not long before the outbreak of war, he retired to Bath, at the age of 60, he set himself to further assiduously and assist practically the development policy of the British Medical Association, which had its origin in the reconstitution of that body in 1902. He had already for ten years studied the interests of the Association in connexion with the medical profession at large, had been elected to the Council and discharged many local responsibilities, and now the leisure of retirement gave him further opportunities of working along lines he loved.

To enumerate the many committees of the Association upon which he served would become tedious from the mere length of the list; it must suffice to say that wherever the conduct of medical practice came into contact with the constitutional or social life of the country to an extent that warranted the institution of a committee for the collection of information or the furtherance of reform, Verrall was always a prominent member of that committee. And to all the varying subjects which thus came within his ken he contributed sagacious counsel which gained in acceptance from the possession of a winning manner, a command of witty words, and obvious sincerity. A member of the Council of the Association since 1893, from 1913 to 1915 he was chairman of the Representative Body, and while occupying that responsible post he was the recipient of the gold medal of the Association in acknowledgment of his services. Of his multifarious Association committees he was at different times chairman of the Organisation, the Medico-Political, and especially of the State Sickness Insurance and the Central Medical War Committee, and his work on the last two was prominent. The institution of national insurance, owing to the sharply divided opinions, both on principle and in detail, as to the merits and demerits of the new legislation, placed the medical profession, and especially the British Medical Association, in a difficult position; while it was felt at the time that the Association was especially fortunate in having a competent body of men prepared to deal with the recurring professional difficulties, among whom none earned, or deserved, higher credit than Verrall and the late Dawson Williams. The Insurance Acts were not in working order when the war broke out, and almost immediately it was realised that much of the available strength of the medical profession would have to be used, and used over a considerable period, for military service, largely with the forces abroad, while the maintenance of the general health of the country was as necessary for the carrying on of hostilities as for the preservation of social conditions. The problem briefly was how far it would be possible to denude the country of medical service while preserving a level of general [illegible]d how at the same time to use those who, by economical arrangement could be set free for military objects, in the most efficient way. A prompt and fair arrangement of recruiting had to be instituted, and to this end the Central Medical War Committee was formed, as a medium between the medical profession on the one hand and, on the other, the War Office and the home population. The circumstances of each locality, and of each medical man residing therein, were inquired into, and as prompt and fair way as possible under which to adjust national claims and individual rights was arrived at. Verrall was chairman of the Committee, and presided over its deliberations with firmness and tact, conducting its complicated business with an expedition that was necessary, even while he showed himself ready in all circumstances to provide a clear and detailed explanation of any decision at which the Committee arrived. At the close of the war his energy and industry were rewarded with a well-won knighthood.

Verrall was first elected a Direct Representative for England and Wales on the General Medical Council in 1911, occupying thus a seat on that body for the unusual duration of 18 years. In discharging his duties on the Council he was never forgetful that he represented the medical profession as a whole and not the Association, and the vote of thanks which was accorded to him at the last meeting of the Association, upon his retirement from the Council, was in accord with a universal feeling in the profession that he had served the public, as well as his own calling, admirably in many important and responsible capacities.

His death occurred, at the age of 77, at East Lodge, Leatherhead, where he had lived for some years.

WILLIAM GORDON, M.D. Camb., F.R.C.P. Lond.,

LATE SENIOR PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

On Oct. 1st, at a nursing home in Exeter, the well-known physician, William Gordon, died as a sequel to a severe attack of influenza in his sixty-seventh year. He was known for his scientific equipment and his zealous pursuit of knowledge, not only in the West of England, but throughout the country.

DR. WILLIAM GORDON.

William Gordon was born at Strabane in 1863, son of Mr. George Gordon, J.P., and was educated privately with such good effect that he *entered* Trinity College, Cambridge, with an exhibition which was later transformed into a scholarship. He justified his boy's promise by securing a first-class in both parts of the Natural Science Tripos, and later pursued his medical studies at University College Hospital, where he was a house physician, and Heidelberg. He qualified as M.B., B.Chir. Camb. in 1890, became M.R.C.P. Lond. in 1891, proceeded to the doctorate in 1894, and in 1903 was elected F.R.C.P.

Gordon commenced medical practice in Exeter, the city in which he passed all his professional life. Early elected to the staff of the Royal Devon and Exeter Hospital, he held also in the Exeter area the posts at various times of physician to the West of England Eye Infirmary and physician to the Exeter Dispensary. His learning and keenness commanded, almost from the beginning, a large domestic and consulting practice, while as a climatologist he was known throughout the scientific world. His deep interest in the subject of tuberculosis was closely associated with his views upon the interplay of meteorological conditions with the incidence of disease. Some of the conclusions which he arrived at were bold, and did not escape challenge, but his investigations into the cause and effect of phthisis in the western counties, and his intensive study of the connexion between the ravages of the disease and the prevalence of certain atmospheric conditions, brought up for consideration many points which too often escape attention. He was as enthusiastic here as he was on the subject of the diagnosis of cancer, and, like all enthusiasts, he made statements which were rather the result of personal belief than of actual proof, but of his intellectual capacity and of his complete sincerity none of his critics had ever any doubt. The Samuel Hyde Lectures on the Place of Climatology in Medicine, delivered in 1913 before the Balneology and Climatology Section of the Royal Society of Medicine, contain in brief his views on a many-sided subject; these were published in THE LANCET on delivery, and were recognised by readers as containing much valuable and suggestive teaching.

Gordon took an active part in the affairs of the British Medical Association, was President of the Section of Medicine at the annual meeting in 1907, and, in particular, was Chairman of a Subcommittee on Army Reform, a subject which deeply interested him. In this connexion, indeed, he is known to have given the late Lord Lansdowne, then Secretary of State for War, much support during the erection of the Army Medical Service into the Royal Army Medical Corps.

Dr. F. A. ROPER sends us for publication the following tribute to his dead friend: "I am glad of this opportunity to pay sad respect to the memory of one whom I have known all my life, and who has been my colleague at the Royal Devon and Exeter Hospital for 16 years. The grief following the loss of one who, during 38 years of active service for the hospital, had built up a commanding reputation in the South-West of England as a physician will readily be understood. At the bedside the dominant characteristic of his work was thoroughness and, arising from that, an earnest striving for precision; and, examination completed, it was then that the knowledge accumulated by his wide experience and lifelong and unremitting study showed themselves. For Gordon remained a student devoted to his books till the very end, and even more intensively so after his retirement from the active staff of the hospital 15 months ago. For his hospital work ever received from him a generous share of his time, and it was no unusual occurrence for him to visit an individual patient daily, or twice daily, where there was any doubtful or difficult problem of diagnosis or treatment to be faced. And his conscientiousness was at once revealed and illustrated to anyone who saw the classified records he kept for his own use of hospital and private cases alike. As a colleague the strength of his firmly marked and impulsive personality showed itself in an unswerving loyalty to, and care for the prestige and honour of his profession, a loyalty which at times evoked criticism by the very forcefulness of its expression; but, ever impatient as he was of opposition, this daunted Gordon not at all, but rather acted as a spur to increased earnestness. As a junior colleague, and friend of his in the personal sense, I can testify that during many years spent in intimate touch with him, frequently over difficult and controversial hospital and private problems, I never on any single occasion experienced from him any but the most scrupulous courtesy, kindness, and encouragement. He ever gave of his best, as the devotion and reliance he commanded of his patients further testified. His intellectual activities outside his profession covered a remarkably wide range. He was an enthusiastic and deeply-read historian, with an extremely retentive memory for facts; a student of architecture; and possessed a considerable degree of artistic ability. Until latterly he was a keen musician, and among his more intimate friends was known as a pianist of sympathetic touch and considerable interpretative insight; while in another direction his book of poems on the war—produced for private circulation only—evidenced among many other traits his admiration and respect for the private soldier. His literary ability was further displayed in his beautifully phrased concise speeches at gatherings, both scientific and social, and his scholarly attainments and methods generally make the gap caused by his loss one that will be felt for many a long day to come. With us his name has been a household word."

Dr. Roper's words set out Gordon's striking characteristics, and the accompanying portrait, taken in middle life, agrees with them.

The grief in Exeter and the surrounding district was accentuated by the unexpected termination to an attack of influenza, as Gordon was carrying on practice in his customary good health until quite recently. He leaves a widow, and an only son of 25, who is in India.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified: Surg. Lt.-Comdr. T. N. D'Arcy to *Warspite* (on transfer of flag); and Surg. Lts. L. J. Corbett to *Warspite* and L. P. Spero to *Queen Elizabeth* (on transfer of flag).

ROYAL ARMY MEDICAL CORPS.

Bt. Lt.-Col. F. D. G. Howell to be Asst. Dir.-Gen., Army Med. Servs., War Office, vice Col. W. R. P. Goodwin (vacated).

Maj. W. R. O'Farrell retires on retd. pay.

Capt. A. R. Barlas to be Maj.

Capt. W. Parsons, late R.A.M.C., is granted a temp. commn. in the rank of Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. J. E. H. Sawyer, having attained the age limit, relinquishes his commn. and retains his rank.

ROYAL AIR FORCE.

Flight Lt. E. J. Jenkins resigns his permanent commission.

INDIAN MEDICAL SERVICE.

Maj. Gen. W. H. S. Nickerson, V.C., late R.A.M.C., to be Dir. Med. Services, India.

COLONIAL MEDICAL SERVICES.

The following appointments are notified: Dr. P. D. Johnson and Dr. J. E. McMahon, Medical Officers, Federated Malay States; Dr. A. W. H. Smith, Assistant Medical Superintendent, Tonjong Rambutan Central Mental Hospital, Federated Malay States; Dr. L. B. Haye, Medical Officer, and Dr. A. W. Rose, Pathologist, Nigeria; and Dr. E. J. Thomas, Medical Officer, Northern Rhodesia.

The following appointments in the West African Medical Staff have also been notified: Dr. G. W. Aynes, Dr. W. C. Davidson, Dr. C. N. Latham, and Dr. C. H. C. White, Medical Officers, and Dr. J. C. B. Craig and Dr. A. D. Cust, Medical Officers of Health.

THE King has granted permission to Lieut.-Colonel Sir Charles H. Bedford, I.M.S. (retd.), to accept and wear the insignia of Knight Grand Cross of the Order of Civil Merit of Spain, conferred upon him by the King of Spain. We understand that the only other British subjects who have received this honour are the Maharajahs of Patiala and of Kapurthala, on the occasion of their State visits to Madrid last year. Apart from other services to Spain for several years past, Sir Charles Bedford originated the King Alfonso XIII Chair of Spanish Studies at the University of Oxford in 1926, commemorating the Prince of Wales's visit to Spanish South America.

Medical News.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

D.P.H.

J. L. Clegg, R. L. Corlett, R. W. Eldridge, A. B. Follows, B. S. Jarvis, J. C. McVittie, R. J. Ormsby, D. E. P. Pritchard, D. Regan, and F. C. Speechly.

THE RED CROSS AND MUSTARD GAS.—The International Committee of the Red Cross offers a prize of 10,000 Swiss francs for a reagent capable of distinguishing without any ambiguity the presence of mustard gas in a concentration of 0·07 mg. per litre of air. The reaction should be characteristic and the reagent and the apparatus submitted should be simple to manufacture and moderate in price when turned out in large quantities. The jury which will decide on the award of the prize will consist of Prof. F. Haber, of Berlin, Sir William J. Pope, F.R.S., of Cambridge, Prof. M. F. Swarts, of Ghent, and Prof. M. G. Urbain, of Paris. Competitors must send their proposals in proper form to the Secretary of the International Committee of the Red Cross, in Geneva, before Dec. 31st, 1930. The reagent adopted will be called by its author's name and will become the property of the International Red Cross.

CHARING CROSS HOSPITAL POST-GRADUATE COURSE. A successful week-end post-graduate course was held in the Medical School on Oct. 5th and 6th, more than a hundred former students of the hospital attending. On Oct. 5th, in the morning, Mr. H. S. Clogg opened the course with a lecture on Diseases of Gall-bladder, and was followed by Mr. Bright Banister on Some Obstetric Difficulties, and by Dr. D. Forsyth on Some Everyday Neuroses. In the afternoon Mr. P. L. Daniel lectured on Common Ailments of the Rectum; Dr. F. G. Chandler on Puncture of the Chest: Its Occasions and Technique; and Dr. J. M. H. MacLeod on Tuberculosis of the Skin. On Sunday, Oct. 6th, the lectures given were as follows:—Mr. H. E. Batten: Fractures. Dr. Gordon Holmes: Syphilis of the Nervous System. Mr. Norman Lake: Injection Treatment of Varicose Veins. Dr. Howard Jones: A Short Review of Anæsthetic Practice. Dr. W. J. Adie: Early Symptoms of Some Common Nervous Disorders. Mr. E. D. Davis: Ear, Nose, and Throat Work in General Practice.

CHARING CROSS HOSPITAL DINNER.—The annual dinner of past and present students coincided with the first week-end post-graduate course ever held at the hospital, and was for this reason more than usually well attended. Nearly 100 covers were laid at Gatti's Restaurant on the evening of Oct. 5th when Dr. J. M. H. MacLeod took the chair and the toast list was agreeably short in order to give time for an admirable programme of music arranged by Dr. Taylor Harris. Mr. Norman Lake, in proposing "Hospital and Medical School," spoke of the completion of the additional wing which would relieve the general wards of overcrowding by providing a complete unit for the skin, orthopædic, dental, and other departments. Mr. J. Bright Banister, who replied in the absence, through illness, of the Dean, Dr. F. H. Young, recounted the signs of prosperity in the school and the prospect of an increasing number of students. Dr. W. C. Bosanquet proposed "The Chairman," who made a graceful reply. Among the items in the musical programme were three songs by Dr. Harris himself rendered with refreshing vigour and faultless technique, and a version, by Mr. Nelson Jackson, of Hamlet describing a cocktail.

ST. THOMAS'S HOSPITAL DINNER.—The annual dinner was held on Oct. 4th at St. Thomas's House, with Dr. H. G. Turney in the chair. There was an attendance of old students to the number of nearly 200, of every degree of seniority, who evidently appreciate the amenity of being able to meet and dine together in their own house. Among the invited guests were the Directors-General of the three medical services, the President of the Royal College of Physicians, the medical officer of health and the coroner for the area, a representative of London University, the headmaster of the Merchant Taylors School, and the architect of the new building. Dr. Turney, in proposing "Hospital and Medical School," opened with an amusing dissertation on doctors who are not doctors, but have deviated before or after qualification into one or other of the pleasant by-ways of life. He noted the curious fact that after being patron saint of the hospital for 300 years Thomas à Becket had been supplanted by the apostle of that name, and he pleaded with the treasurer for the restitution of the all-British patron. The partial eclipse consequent on the transplantation of the ancient hospital from the borough to its present site had, he felt, now fully disappeared. Sir Arthur Stanley, in replying, offered to look round for the best saint of the name, and spoke of the past year as one of extreme importance in the history of the hospital. For 12 years past he had been receiving demands on every hand for more accommodation. They were not allowed to build bridges, to approach the new site on the south side of Lambeth Palace-road, and tunnels must be so deep as to run the risk of flood. The new scheme would therefore transplant the medical school so as to build in its place a worthy out-patient department adjoining the wards. A joint appeal was shortly to be issued for certainly not less than £500,000, in the collection of which he looked hopefully to the aid of St. Thomas's men. The Dean, Prof. L. S. Dudgeon, replied for the medical school, sketching in a few sympathetic words the careers of the great men who had been lost to the school in the past year—Sharkey, Mackenzie, Caiger, George Maling, V.C., E. L. Atkinson, R.N., a member of Scott's expedition—and passing on to those retiring from the staff, especially Dr. J. S. Fairbairn, a man of ideas, a first-rate teacher and organiser, and a fine physician. Dr. H. Yellowlees had succeeded Dr. W. H. B. Stoddart, Prof. S. J. Cowell had delivered his first course on dietetics, Sir George Makins had received the honorary gold medal of the Royal College of Surgeons, a worthy successor of Lister and Paget. Finally he remarked that the new medical school would be six storeys in height, would cost £220,000, and would contain on the top 24 bedrooms supplementary to those in St. Thomas's House. Sir Percy Sargent proposed "The Guests," and Sir John Rose Bradford replied; it was, he said, a pleasing feature to entertain guests from other schools who had not much opportunity of meeting. The toast of "The Chairman" was proposed by Dr. A. E. Russell, who spoke of the service which Dr. Turney, after ten years of retirement, was still rendering to the hospital in his attendance on the nursing staff and as an almoner. The dinner concluded with the presentation of an illuminated address and a cheque to the school bedell, whose service with that of his father and grandfather covered a period of over 100 years.

ST. GEORGE'S HOSPITAL DINNER.—The annual dinner of the hospital and medical school was held on Oct. 1st at the Hyde Park Hotel with Dr. Digby Cotes-Preedy, K.C., in the chair. More than 100 past and present St. George's men attended, and a most enjoyable evening was spent. In reply to the toast of the "Hospital and Medical School" the Dean, Dr. Anthony Feiling, stated that the school *had had a successful* year, and that an excellent entry of new students was assured. The health of "The Chairman" wittily proposed by Mr. Ivor Back was replied to in like vein.

ST. MARY'S HOSPITAL DINNER.—Sir John Broadbent presided at the annual dinner at the Trocadero Restaurant on Oct. 4th, when the toast of "St. Mary's Hospital and Medical School" was proposed by Lieut.-Colonel H. E. Verey, as chairman of the Hospital Board. After referring to the large sums the School had received by the gift of Lord Beaverbrook and the bequest of Lord Revelstoke, Colonel Verey said it was hoped that rebuilding would begin early next year. If possible, work would start at the same time on the new inoculation department, for which Lord Iveagh's generous donation of £25,000 over a period of seven years would bring in a total of about £40,000. On the site of the old medical school a nurses' home would be built to accommodate four or five hundred, whilst the present nurses' home would provide ideal accommodation for paying patients—a most urgent necessity. The extensions of the hospital coming into operation this year had cost £63,000, of which £62,000 had been raised. The operating theatres were now as modern as any in the country, and the increase in the number of beds would mean better service for the locality. Colonel Verey congratulated the School on winning the Inter-hospital Cricket Cup, which had been absent since 1890. He went on to pay a tribute to Mr. Warren Low, whom he described as a tower of strength to the Hospital Board. He trusted that after Mr. Low's retirement from the surgical staff in November the Board would continue to enjoy his wise advice and tactful help. Another resignation which would be deeply regretted was that of Mr. Leslie Paton from the post of ophthalmic surgeon. In his reply, Dr. C. M. Wilson, the Dean, said it had been a wonderful year for the School, whose record, indeed, during the last ten years had been a romance. The late war had made the task of every medical school very difficult; expenses had been quadrupled, whilst income remained the same. Those who held that there were too many medical schools had welcomed this situation because they thought it would eliminate the weakest, but it was remarkable that the two most threatened with destruction—namely, the Middlesex and St. Mary's—were the two which had gone ahead most of all in recent years. St. Mary's had secured £160,000 for new school buildings, and hoped to get the remainder needed. They were out to make it the best school in London—best not because it had the best buil" or even the best staff, but because it had the best students. Sir John Broadbent, whose health was drunk with musical honours, responded entertainingly to the toast, and took occasion to recall the merits of many of his colleagues. The proceedings closed with a speech from the captain of the cricket team, the health of which was proposed by the chairman.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LTD.—The annual meeting of this Society was held on Oct. 7th under the chairmanship of Dr. F. J. Allan. The chairman in his address stated the report showed the Society had had a successful year. The premium income in the Sickness Fund was now £60,700. The sickness claims paid had increased from £31,000 to £38,196, chiefly on account of the influenza epidemic, for which claims were paid amounting to £6200. The total of the funds at the close of the year was £383,761. New life assurance policies were issued for £243,460 gross, and the funds had increased to £222,722. The total premium income of the Society was £98,050, and expenses of administration £13,348. The management expenses showed a gratifying fall in the ratio to premium income from 13·8 per cent. to 13·4 per cent. The gross rate of interest earned over the whole funds was £5 0s. 3*d.*, and net rate £4 3*s.* 2*d.* Dr. Allan stated that the investments of the Society were in a sound condition, and the auditors certified that the market prices of the stocks at June 30th, 1929, were £11,786 in excess of the values stated in the balance-sheet. The total funds of the Society now amounted to £628,588.

Dr. Harvey Hilliard, in moving three resolutions in respect of permanent sickness insurance contracts to age 70, fixing the date of the annual meeting, and printing and publishing a list of members, said that when he sent these to the office to be placed on the agenda of the meeting he was informed that they were matters arising out of the report, but he maintained that this was not the correct procedure. The chairman replied that he was informed by the legal advisers of the Society that the procedure adopted was in accordance with that usually adopted by other companies, but that the Board was prepared to consider a scheme for extending permanent sickness insurance to age 70. In the matter of fixing the date of the meeting, it was decided that the date should be published in the medical press six weeks beforehand. The motion for publishing a list of members being put to the meeting was lost by a large majority. The report was adopted, and the two retiring directors, Sir William Willcox and Mr. W. H. Dolamore, were duly re-elected. Dr. Harvey Hilliard's motion that all directors of the Society should retire at age 65 was withdrawn by him. After a vote of thanks had been unanimously passed to Dr. Allan the meeting closed.

GRESHAM LECTURES.—Four lectures on How England Learned to Control Disease will be given by Sir George Newman at 6 P.M. on Oct. 15th, 16th, 17th, and 18th, at Gresham College, Basinghall-street, London, E.C.

GUILD OF ST. LUKE.—The Annual Medical Service will be held at Westminster Abbey on Sunday, Oct. 20th, at 6.30 P.M., when the Bishop of Bradford will be the preacher. Medical men, women, and students are invited to attend. Those wearing academic dress will not require tickets, but will proceed to the Jerusalem Chamber and robe there. Tickets for others and their friends may be had from the Secretary of the Guild, King's College, Strand, London.

NATIONAL COUNCIL FOR MENTAL HYGIENE.—A conference on mental health will be held in the Central Hall, Westminster, from Oct. 30th to Nov. 2nd. The subjects to be discussed include Sex Education, the Personal Equation in Industry, the Child and the Parent, and Delinquency. There will also be group discussions on the Working of the Juvenile Courts, the Relation of the Work of Public Health Nurses and Social Workers to the Mental Health of the Community, and the Problem Child at Home and in School. Further particulars may be had from the Secretary of the Council, 78, Chandos House, Palmer-street, London, S.W. 1.

BRITISH SCIENCE GUILD.—The Norman Lockyer Lecture for 1929 will be given at the Goldsmiths' Hall, Foster-lane, London, E.C., at 4.30 P.M., on Tuesday, Nov. 19th, by Sir Walter Fletcher, F.R.S., Secretary of the Medical Research Council, who will speak on certain aspects of medical research and their applications.

A lecture has been established in memory of Sir Alexander Pedler, F.R.S., who was for many years honorary secretary of the Guild. The first Alexander Pedler Lecture will be given at Manchester, at 5.30 P.M., on Nov. 26th by Mr. G. C. Simpson, F.R.S. The subject will be Past Climates, and the lecture will be held under the auspices of the Manchester Literary and Philosophical Society at 36, George-street.

POST-GRADUATE COURSE ON ORTHOPÆDICS.—A fortnight's course will be held at the Royal National Orthopædic Hospital, London, from Nov. 18th to 30th. Particulars will be found in our advertisement columns.

INTERNATIONAL LEAGUE AGAINST TRACHOMA.—At the International Ophthalmological Congress recently held in Holland (see THE LANCET, Sept. 21st, p. 633) it was resolved to form an International League against Trachoma. Prof. Emile de Grósz, of Budapest, was elected president, and Dr. F. Wibaut, of Amsterdam, secretary, and they were entrusted with the formation of a committee from among the delegates of the ophthalmological societies and leagues already in existence. Prof. de Grósz's address is Baross-u., 10, Budapest VIII.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 28TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 108 (last week 119); scarlet fever, 2590; diphtheria, 1367; enteric fever, 101; pneumonia, 720; puerperal fever, 46; puerperal pyrexia, 86; cerebro-spinal fever, 10; acute poliomyelitis, 37; acute polio-encephalitis, 4; encephalitis lethargica, 12; continued fever, 1; dysentery, 11; ophthalmia neonatorum, 100. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Oct. 1st–2nd was as follows:—Small-pox, 143 under treatment, 10 under observation (last week 122 and 19 respectively); scarlet fever, 1738; diphtheria, 1764; enteric fever, 18; measles, 172; whooping-cough, 190; puerperal fever, 24 (plus 8 babies); encephalitis lethargica, 126; poliomyelitis, 5; "other diseases," 13. At St. Margaret's Hospital there were 10 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 12 (2) from measles, 6 (0) from scarlet fever, 15 (3) from whooping-cough, 31 (9) from diphtheria, 186 (36) from diarrhœa and enteritis under two years, and 23 (5) from influenza. The figures in parentheses are those for London itself.

Of the deaths from diarrhœa (which have increased by a bare quarter), 31 were reported from Birmingham, 18 from Liverpool, 12 from Sunderland, 11 from Hull, 8 from Manchester, 7 from Middlesbrough, and 6 from West Ham; while Glasgow, Dublin, and Belfast reported 15, 8, and 7 respectively. The deaths from enteric fever were reported from Wimbledon, Newcastle-on-Tyne, and Swansea.

The number of stillbirths notified during the week was 236 (corresponding to a rate of 35 per 1000 births), including 43 in London.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Oct. 14th.—5 P.M., WAR. Presidential Address by Group-Captain Hardy V. Wells, R.A.F.

TUESDAY.—8 P.M., PATHOLOGY. Prof. A. E. Boycott: The Blood as a Tissue (Presidential Address). 8.30 P.M., ORTHOPÆDICS. Dr. Fred Albee (New York) will give an Address on Original Surgical Applications of the *Bone Graft*, illustrated by lantern slides and moving pictures. Members of the Section of Surgery are cordially invited to attend.

WEDNESDAY.—8 P.M., TROPICAL DISEASES. Dr. G. Giglioli: Paratyphosus Infections in British Guiana—Sterile abscess in Treatment—Demonstration of Specimen. Dr. W. Broughton-Alcock: Section Showing Structures Morphologically Resembling Spirochætes of a Species Common to the Mouth, lying deep within its mucous membrane (for opinion).

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.)

FRIDAY.—8 P.M., OBSTETRICS, COMPARATIVE MEDICINE. Special Discussion on Causes of Early Abortion and Sterility. Openers: Prof. A. Robinson and Prof. Beckwith Whitehouse (Obstetrics); Mr. J. R. Barker and Mr. O. Stinson (Comparative Medicine). 8.30 P.M., ELECTRO-THERAPEUTICS. Presidential Address by Dr. C. A. Robinson.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Oct. 14th.—8 P.M., Annual General Meeting. 8.30 P.M., Mr. Donald Armour: Some of Lettsom's Contemporaries (Presidential Address).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.
Thursday, Oct. 17th.—7.45 P.M., Demonstration of some of Dr. Low's Original Preparations showing the Development of Filariæ in Mosquitoes.—8.15 P.M., Dr. G. Carmichael Low: A Retrospect of Tropical Medicine from 1891–1914 (Presidential Address).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.
Friday, Oct. 18th.—5 P.M., Sir Arthur Keith: Specimens of Trephining—Ancient and Modern.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Monday, Oct. 14th, to Saturday, Oct. 19th.—Medical Society of London. Mon., 5 P.M., Dr. F. G. Chandler: The Treatment of Pulmonary Tuberculosis. No fee. Tues., 8.30 P.M., Dr. Parsons-Smith: The Symptoms and Signs of Myocardial Failure. Fri., 8.30 P.M., Dr. Parsons-Smith: The Treatment of Heart Disease. St. John's Hospital for Diseases of the Skin. Mon. 2 to 4 P.M., Dr. W. *Griffith: Demonstration. No* fee.—Samaritan Hospital, Marylebone-road, N.W. Thurs., 2.30 P.M., Mr. Andrew McAllister: (Gynæcology) Demonstration. No fee.—Hospital for Tropical Diseases, 25, Gordon-street, W.C. Tues. and Thurs., 2 P.M., Lecture-demonstrations by Dr. Manson-Bahr and Dr. Carmichael Low.—Chelsea Hospital, Arthur-street, S.W. Special Courses in Gynæcology for two weeks.—Hospital for Sick Children, Great Ormond-street, W.C. Special morning course.—Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C. Intensive Course. Further particulars from the Fellowship of Medicine.

LONDON HOSPITAL POST-GRADUATE COURSE.
Wednesday, Oct. 16th.—10.15–10.45 A.M., Dr. Russell Brain: The Therapeutic Uses of Luminal. 11–11.30 A.M., Dr. W. W. Woods: The Causes of Sudden Death (with specimens). 11.30–11.45 A.M., Dr. S. Phillips Bedson: Recent Work on Vaccination. 12–12.45 P.M., Mr. Hugh Lett: Hematuria. 1.30–2 P.M., Sir R. S. Woods: The Present Position of General Light Therapy. 2–3 P.M., Mr. W. S. Perrin: Demonstration of Cases Treated by Radium. 2–4 P.M., Mr. E. C. Lindsay: Surgical Operations. 2–3.30 P.M., Dr. George Riddoch: Demonstration of Neurological Cases. 3.45–4.30 P.M., Dr. John Parkinson: Non-valvular Disease of the Heart (Cases and Lantern slides).
Thursday.—10–10.45 A.M., Dr. W. J. O'Donovan: Occupational Dermatitis (Lantern Demonstration). 11–11.45 A.M., Dr. Maitland-Jones: Infant Feeding. 11.55 A.M.–12.10 P.M., Dr. Donald Hunter: Modern Treatment of Lead Poisoning. 12.15–12.45 P.M., Mr. Alan Perry: Injection Treatment of Varicose Veins (Lecture and Demonstration). 1.30–2 P.M. Mr. H. S. Souttar: Radium and Its Surgical Application. 2–3.30 P.M., Mr. Souttar: Surgical Operations; Dr. R. A. Rowlands and Mr. J. D. Driberg: Ward Demonstrations. 3.45–4.30 P.M., Dr. O. Leyton: Diabetes.
Friday.—10–10.45 A.M., Prof. A. W. M. Ellis: Use and Abuse of Intravenous Therapy. 11–11.45 A.M., Dr. P. N. Panton: Pernicious Anæmia. 12–12.45 P.M., Mr. Robert Milne: Pain in the Fore Part of the Foot. 1.30–3.30 P.M., Mr. A. J. Walton: Operations. 1.30–2.30 P.M., Dr. A. E. Clark-Kennedy: Cardiac Pain (Ward Demonstration). 2.30–3.30 P.M., Dr. Theodore Thompson: Ward Demonstration. 3.45–4.30 P.M., Mr. Eardley Holland: Uterine Hæmorrhage (Gynæcological Demonstration). 9 P.M., Dr. Ashley Daly: Methods of Anæsthesia (Demonstration).
Saturday.—10–10.45 A.M., Dr. Robert Hutchison: Dyspepsias of Childhood. 11 A.M. to 12 noon, Mr. Russell Howard: Ward Demonstration. 12–12.45 P.M., Mr. Walton: *Place of Surgery in Lesions of the* Stomach.

NATIONAL HOSPITAL, Queen-square, W.C.
Monday, Oct. 14th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Adie: Disseminated Sclerosis.
Tuesday.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Critchley: Central Disorders of Vision.
Thursday.—2 P.M., *Dr. Kinnier Wilson: Out-patient* Clinic. 3.30 P.M., Dr. Riddoch: Some Heredo-familial Diseases.
Friday.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educational Methods (in Exercise Room).

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General *Hospital*, Tottenham, N.
Monday, Oct. 14th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
Tuesday.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
Wednesday.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
Thursday.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.
Friday.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
Monday, Oct. 14th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Ward Visit. 2 P.M., Mr. Donald Armour: Operations.
Tuesday.—10 A.M., Medical Registrar: Ward Visit. 2 P.M., Dr. Shaw: Medical Out-patients. 4.30 P.M., (lecture), Mr. Tyrrell Gray: Surgical Aspects of Indigestion.
Wednesday.—10 A.M., Dr. Owen: Children's Out-patient Department. 2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Department. 11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. MacDonald: Genito-Urinary Out-patient Department.
Friday.—10 A.M., Dr. Pritchard: Medical Ward Visit. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.
Saturday.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Children's Medical Out-patient Department. Medical and Surgical Out-patients at 2 P.M., daily. Operations. Special Departments daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M. Special Classes in Anæsthetics and Operative Surgery.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
Tuesday, Oct. 15th.—5 P.M., Dr. H. W. Barber: Bacteriology and Mycology.
Thursday.—5 P.M., Dr. H. G. Burford: Pathology Demonstration.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.
Friday, Oct. 18th.—4 P.M., Mr. A. Wylie: Gleanings and Impressions of Oto-Rhino-Laryngology.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
Wednesday, Oct. 16th.—4.30 P.M., Mr. R. H. Jocelyn Swan: The Examination of a Urological Patient.

INSTITUTE OF HYGIENE, 28, Portland-place, W.
Wednesday, Oct. 16th.—3.30 P.M., Dr. R. King Brown: Prophylaxis Applied to Infectious Diseases.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
Wednesday, Oct. 16th.—4 P.M., Dr. E. Graham Little, M.P.: Health and Conditions of Work of Medical Students.
Friday.—5 P.M., Prof. R. A. Peters: Coördinative Bio-Chemistry of the Cell and Tissues (First Harben Lecture).

GRESHAM COLLEGE, Basinghall-street, E.C.
Tuesday, *Oct.* 15th, and the following Wednesday, Thursday, and Friday.—6 P.M., Sir George Newman: How England Learned to Control Disease (Gresham Lectures).

UNIVERSITY COLLEGE, Gower-street, W.C.
Monday, Oct. 14th.—5 P.M., Dr. R. J. Brocklehurst: Secretion of the Digestive Juices. (First of four public lectures).

KING'S COLLEGE, Strand, W.C.
Tuesday, Oct. 15th.—5 P.M., Mr. J. W. *Pickering, D.Sc.*: Blood Plasma and Platelets (Second lecture).
Thursday.—5 P.M., Mr. J. A. Hewitt, D.Sc.: Metabolism of the Carbohydrates and Fats. (First of four lectures).

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, Albert Embankment, S.E.
Tuesday, Oct. 15th.—5 P.M., Dr. A. St. G. Huggett: Physiology of the Fœtus (Second lecture).

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.
Monday, Oct. 14th.—6 P.M., Prof. T. Madsen (Copenhagen): Seasonal Variations of Epidemic Diseases.
Wednesday.—6 P.M., Prof. Madsen: Milk Epidemics.
Friday.—6 P.M., Prof. Madsen: Diphtheria Toxin and Antitoxin.

KING'S COLLEGE FOR HOUSEHOLD AND SOCIAL SCIENCE, Campden Hill-road, W.
Friday, *Oct.* 18th.—5 P.M., Prof. V. H. Mottram: Human Nutrition (First of six lectures).

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
Tuesday, Oct. 15th.—4.15 P.M., Dr. D. E. Core: Functional Pain.
Friday.—4.15 P.M., Dr. G. Jessel: Differential Diagnosis of Pulmonary Tuberculosis (Illustrated by Skiagrams).

Appointments.

Bligh, J. M., M.D. Liverp., M.R.C.P. Lond., has been appointed Hon. Consulting Physician to Southport Infirmary.

Churcher, D. G., M.D., B.S. Lond., a Medical Referee under the Workmen's Compensation Act for Eastbourne and Hastings County Court Districts.

Claye, A. M., M.D. Leeds, F.R.C.S. Eng., Honorary Obstetric Surgeon to Leeds Maternity Hospital.

Dearn, E. M., M.B., Ch.B. Sheffield, Assistant School Medical Officer to the Newcastle Education Committee.

Johnson, R. G., Certifying Surgeon under the Factory and Workshop Acts for Bristol District, Gloucester.

Lobban, G. M. D., M.B., Ch.B. Leeds, School Medical Officer, Essex County *Council*.

Watson, Jessie R., M.B., Ch.B. St. And., Assistant School Medical Officer, Sunderland.

Bolton Infirmary.—**Biggane, E. F.**, M.B., Ch.B. N.U.I., and **Critchley, S. E.**, M.B., Ch.B. Manch., Assistant Surgeons.

City of London Maternity Hospital, City-road, E.C.—**Freeman, L. W.**, L.R.C.P. Lond., M.R.C.S., Resident Medical Officer; and **Price, J. A.**, M.B., B.Ch. Belf., Assistant Resident Medical Officer.

Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Elder Professor of Anatomy and Histology. £1100.

Bath, Royal United Hospital.—H.P. At rate of £120.

Barnstaple Dispensary, Area of the County of Devon.—Tuber. O. £750.

Bedford County Hospital.—H.S. Also Asst. H.S. At rate of £175 and £130 respectively.

Bethlem Hospital, Lambeth-road, S.E.—Res. H.P. £25 per quarter.

Birmingham City Hospital for Infectious Diseases, Little Bromwich.—Temporary Asst. M.O. At rate of £300.

Birmingham, Queen's Hospital.—Res. Anæsthetist. £70–£100.

Birmingham, Selly Oak Hospital.—Cas. O. at rate of £200.

Birmingham and Midland Ear and Throat Hospital.—Asst. Surg. O. £200.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.P. At rate of £120.

Bradford Royal Eye and Ear Hospital.—Jun. H.S. £120.

Bradford Royal Infirmary.—Hon. Asst. P. Also H.P. £150.

Brighton, New Sussex Hospital for Women and Children.—Hon. Asst. Ophth. Surg. Also Hon. Anæsthetist.

Cambridge House Infant Welfare Centre, Camberwell.—M.O. £1 11*s.* 6*d.* per session.

Canterbury, Kent and Canterbury Hospital.—Third Res. M.O. At rate of £125.

Carlisle, Cumberland Infirmary.—H.P. At rate of £155.

Chelmsford and Essex Hospital.—Res. M.O. At rate of £150.

Darlington County Borough.—Deputy M.O.H. £750.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Anæsthetist. £10 10*s.*

Exeter, Royal Devon and Exeter Hospital.—Aural H.S. and Cas. O. At rate of £120.

Glasgow, Woodilee Mental Hospital, Lenzie.—Jun. Asst. M.O. £300.

Great Yarmouth General Hospital.—Jun. H.S. £100.

Halifax Royal Infirmary.—Third H.S. At rate of £100.

Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.S. Also Cas. M.O. and Cas. Surg. O. Each at rate of £100.

Hereford General Hospital.—H.P. At rate of £150.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Jun. H.P. for Frimley Sanatorium. At rate of £100.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100. Res. M.O. Also H.P. At rate of £150 and £100 respectively.

Hôpital Français, 172, Shaftesbury-avenue, W.C.—Jun. Res. M.O. £100.

Huddersfield Royal Infirmary.—Jun. H.S. At rate of £150.

Hull Royal Infirmary.—Third H.S. Also Asst. H.P. At rate of £150 and £130 respectively.

Ilford Emergency Hospital.—Hon. Radiologist. £50.

Inverness Northern Infirmary.—Hon. Radiologist.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Loughboro' Junction Maternity and Infant Welfare Centre, 109, Sussex-road, S.W.—Medical Woman.

Macclesfield General Infirmary.—Second H.S. At rate of £150.

Manchester, St. Mary's Hospital—Four H.S.'s. Each at rate of £50.

Manchester, Baguley Sanatorium.—Sen. Asst. M.O. £500. Also Asst. M.O. £350.

Manchester, Salford Royal Hospital.—H.S. to Orthopædic Dept. Also Cas. H.S. Each at rate of £125.

Margate, Royal Sea Bathing Hospital.—H.S. At rate of £200.

Metropolitan Ear, Nose, and Throat Hospital.—H.S. £150.

Metropolitan Hospital, Kingsland-road, E.—H.P.'s, H.S's., &c. Each at rate of £100.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Jun. Res. M.O. Also Asst. Cas. O. Each at rate of £100.

Miller General Hospital, Greenwich-road, S.E.—Orth. H.S. At rate of £150. Hon. Surgeon. Also Hon. Physician to Skin Dept.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Surgeon.

Norwich, Norfolk and Norwich Hospital.—H.P. £120.

Nottingham General Dispensary.—Res. Surg. £250.

Preston and County of Lancaster Royal Infirmary.—Res. Surg. O. £300. Also H.S. At rate of £150.

Prison Medical Service.—Medical Officer. Class II. £350.

Queen's Hospital for Children, Hackney-road, E.—H.P., Cas. O., and H.S. All at rate of £100.

Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.

Rotherham Hospital.—H.P. £180.

Royal Chest Hospital, City-road, E.C.—H.P. At rate of £100.

Royal Eye Hospital, St. George's Circus, Southwark, S.E.—H.S. Also Asst. H.S. At rate of £150 and £100 respectively.

Royal Free Hospital and London (R.F.H.) School of Medicine for Women, W.C.—Obstet. and Gyn. Unit. Sen. Asst. At rate of £350. Third Asst. £270. Path. Dept. Res. Asst. Path. £150.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Hon. Asst. Surg. Also Surg. Registrars. Each £105.

Royal Naval Dental Service.—Dental Officers.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. Gynæcological Reg. Also H.S. At rate of £100.

St. Andrew's Hospital, Dollis Hill, N.W.—Sen. and Jun. Res. M.O.'s.

St. Helen's County Borough.—Tuber. O. £600.

St. John's Hospital, Lewisham, S.E.—Res. Cas. O. and Res. H.P. Each at rate of £100. Radiologist. Also Res. M.O. At rate of £100.

St. Mary's Hospital, Institute of Pathology and Research.—Research Studentship. At rate of £200.

St. Peter's Hospital for Stone, Henrietta-street, W.C.—Radiologist. £25.

Salisbury General Infirmary.—Res. M.O. £150.

Sheffield, South Yorkshire Mental Hospital.—M.O. £400.

Southampton, Royal South Hants and Southampton Hospital.—Cas. O. At rate of £120.

Swanley, Kent, Alexandra Hospital for Children with Hip Disease. Res. Asst. M.O. At rate of £300.

University College Hospital, Gower-street, W.C.—Hon. Clin. Asst.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. Med. Reg. Also Hon. Surg. Reg.

West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Asst. Physician.

West London Hospital, Hammersmith, W.—Hon. Registrar for Throat, Nose, and Ear Dept. Asst. M.O. At rate of £450. Also three Jun. Asst. M.O's. Each at rate of £350.

Westminster Hospital, Broad Sanctuary.—Wander Scholarship, &c. £250.

Woolwich and District War Memorial Hospital, Shooter's Hill, S.E. Res. M.O. £175. Also H.S. At rate of £125.

Wolverhampton, Royal Hospital.—H.S. Also Cas. O. and Res. Anæsthetist. At rate of £150 and £125 respectively.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at West Hartlepool (Durham) and Montrose (Angus).

Births, Marriages, and Deaths.

BIRTHS.

Bedson.—On Sept. 29th, at Arkwright-road, Sanderstead, the wife of Dr. S. P. Bedson, of a son.

Buckley.—On Sept. 29th, at Lorna Lodge, Barlow Moor-road, Didsbury, the wife of G. H. Buckley, F.R.C.S. Edin., of Blackpool, of a daughter.

Cooper.—On Sept. 29th, at The Georgian House, Chipstead, the wife of A. Basil Cooper, M.B., of a daughter.

MARRIAGES.

Batchelor—Glendinning.—On Oct. 1st, at St. Paul's Church, Lorrimore-square, G. F. Grant Batchelor, F.R.C.S., to Louise, daughter of the late Mr. and Mrs. John Glendinning, Dumfries.

McCay—Dobbie.—At Edinburgh, on Oct. 7th, 1929, Andrew William McCay, F.R.C.S.E., Chester, to Elsie Margaret, elder daughter of Sir Joseph and Lady Dobbie, 10, Learmonth-terrace, Edinburgh.

Middleton—Lavanchy-Clarke.—On Oct. 2nd, at the Scottish Church, Lausanne, Switzerland, E. L. Middleton, M.D., D.P.H., of London, to Bertha Jane, daughter of the late F. H. Lavanchy-Clarke and of Mrs. Lavanchy-Clarke, of Cannes.

DEATHS.

Brownfield.—On Oct. 5th, Harry Munyard Brownfield, O.B.E., V.D., M.R.C.S., L.R.C.P., of Lennox-road North, Southsea.

Frakes.—On Sept. 20th, suddenly, at Homecroft, Oakley, Hants, Henry Sowter Frakes, M.D., aged 77.

Gordon.—On Oct. 1st, at Exeter, William Gordon, M.A., M.D. Camb., F.R.C.P. Lond., Consulting Physician to the Royal Devon and Exeter Hospital and West of England, Eye Infirmary, in the 67th year of his age.

O'Leary.—On Oct. 7th, at Yateley Lodge, Yateley, Hants suddenly, following an operation, Arthur Price Evelyn O'Leary, M.R.C.S., L.R.C.P., late of Glenelg, South Australia, aged 62.

Pywell.—On Sept. 30th, at Fletton-avenue, Peterborough, Ernest Alfred Pywell, M.R.C.S., L.R.C.P., aged 43.

Verrall.—On Oct. 4th, at East Lodge, Leatherhead, Sir Thomas Jenner Verrall, M.R.C.S., L.R.C.P., LL.D.

Woodman.—At the Royal Hospital, Baghdad, on Sept. 10th, from hæmorrhage during enteric fever, Margaret Maxwell, dearly loved wife of G. S. Woodman, F.R.C.S. Ed.

N.B.—A fee of 7s. 6d is charged for the insertion of Notices of Births, Marriages, and Deaths.

London School of Dermatology.—The winter session began on Oct. 3rd with an opening lecture on the Rise and Progress of Dermatology delivered by Dr. J. H. Stowers at St. John's Hospital for Diseases of the Skin, Leicester-square. Lectures will be given every Tuesday and Thursday throughout the winter months.

Guild of St. Luke, St. Cosmas, and St. Damian.—The general meeting of the Guild will be held in the Cathedral Hall, Archbishop's House, on Sunday, Oct. 20th, immediately after the High Mass at Westminster Cathedral, which will be celebrated at 10.30 A.M. The annual report of the council of the Guild records a successful year, special mention being made of the care and helpful direction applied to every activity of the Guild by the Master, Mr. Ernest Ware. The hon. secretary of the Guild is Dr. W. J. O'Donovan, of 123, Harley-street, W.1, from whom further information may be obtained.

Notes, Comments, and Abstracts.

OBSERVATIONS IN ICELAND.

HISTORY AND HEALTH.

(FROM A SPECIAL CORRESPONDENT.)

(*Concluded from p. 750.*)

Other Diseases.

Enteric fever has long been endemic in Iceland, with serious outbreaks from time to time. In the period 1911–20 the annual notifications numbered 155, and in the following five-year period 110. In 1927 only 27 cases were notified. The disease has been most frequent in the towns in spite of a good water-supply, tolerably good drainage, and a standard of cleanliness higher, at any rate, than that of the country districts, where the disease is usually limited to single farms. The disease is often of a mild type, some of the cases being paratyphus. It is most frequent in the first and last quarters of the year. Much of the milk is pasteurised in Reykjavik.

Last century *scarlet fever* invaded the country periodically from abroad, each epidemic running through the country for three or four years, and then dying out completely. Early in the present century it became endemic. The last epidemic, which began in 1909, differed in certain respects from previous epidemics; its maximum was reached in 1920, when there were 700 cases, and it had almost died out by the end of 1924. Its extensive distribution and mild character rendered preventive measures difficult as well as superfluous, and isolation was but little enforced except in Reykjavik. In 1927 only five cases were notified.

Diphtheria was waning in the period 1908–19, but in 1920 a new epidemic wave began, reaching its maximum in 1921, and almost dying out in 1926. In the five-year period 1921–25 there were 201 cases notified annually. In 1926 only 71 cases were notified, mostly mild, and in 1927 this figure was further reduced to 26.

Acute anterior poliomyelitis had been rare in Iceland till 1924, when a serious epidemic broke out suddenly, the first case notified being in Reykjavik. There were 403 cases notified, with 89 deaths, in this year, and in 1925 25 new cases were notified. The epidemic raced through the country in about four months, being most severe in the north and west. As in the case of influenza, this epidemic reached its maximum in its second month. The most remarkable feature of this epidemic was the frequency of abortive cases (two-thirds of all cases according to one medical officer). Another medical officer found 11 abortive cases out of a total of 18. The disease was characterised by a slight sore-throat, nausea or vomiting, and sometimes by diarrhœa, slight fever, headache, and pain or stiffness in the back. Most of the patients recovered rapidly. In some cases the reflexes were a trifle impaired during convalescence from an abortive attack. About half of the members of three families, closely observed during the epidemic, showed some sign of the disease. Patients often had a slight attack without any paralysis at first, but on exertion or exposure a relapse occurred, and this was followed by paralysis. Strict confinement to bed from the onset of symptoms and for a week or two after recovery proved necessary. The proportion of patients who became paralysed varied from 15 to 25 per cent. Twenty-one cases of lethargic encephalitis, with seven deaths, were notified in the five-year period 1921–25.

An epidemic of *whooping-cough* was imported from Denmark in 1926. It raged throughout the country during 1927, as many as 6045 cases being notified, with 155 deaths. As many as 90 of these deaths occurred in the first year of life. Many adults, however, also suffered, several of them catching the disease for a second time. On the other hand, many children proved to be immune, and one medical officer observed that approximately one-third of the children who had been exposed to the disease did not develop it. Some medical officers succeeded by preventive measures in keeping their districts partially or totally free. In Akureyri the advent of the epidemic was greeted by the women of the town in a manner as drastic as it was effective. They formed a cordon round the infected district, and so effective was the day and night watch which the pickets kept that the rest of the town was saved. Preventive vaccination was apparently successful in the hands of several medical officers, and 73·4 per cent. of 158 vaccinated children failed to catch the disease, while 21·5 per cent. caught it only in a mild form. The remaining 5·1 per cent. caught it badly.

In 1922 the Icelandic Medical Society launched a campaign against *favus*, and though only 58 cases were discovered it is probable that this was little more than half the total. With the financial aid of the Government, measures for stamping out the disease were adopted, and in 1925 70 cases were discovered and cured.

Malignant disease is slightly on the increase, but cancer of the uterus still remains remarkably rare. The anatomical distribution of malignant growths notified in Reykjavik was as follows: stomach, 54 per cent.; breast, 14·4 per cent.; œsophagus, 5·8 per cent.; colon, 5·6 per cent.; and uterus, 4·8 per cent.

While *diabetes* is very rare, the rarity of *rickets* is in dispute. In one small district a medical officer, with special training in pædiatrics, found that not less than 18 per cent. of the children under the age of two suffered from this disease. So it may be that rickets in a mild form is not as rare as it was formerly supposed to be, but it is far from being as common as in the Faröe Islands, where 42 per cent. of the children have been found to be rachitic.

Cerebral apoplexy is such a frequent cause of death that in the five-year period 1921–25 there were no fewer than 81 deaths a year from this cause (8·5 per 10,000 inhabitants). This is the more surprising as syphilis is a most rare disease in Iceland. Some curious observations suggest that cerebral apoplexy is an hereditary disease.

Conclusions.

Iceland's public health problems may seem at first sight to be those of any other community, to be solved in the same ways that countries with an older public health service have found to be most satisfactory. But in many respects Iceland is unique, and the features which make it so justify it in adapting, rather than adopting blindly, the ideas and measures of the rest of the world. Take such a matter as the isolation of whole districts when epidemics have reached the country from abroad. As we have seen in the case of measles and influenza, barriers can be raised which are effective, for a time at any rate, against most highly infectious diseases whose very ætiology and mode of dissemination are still largely unknown. Even when such preventive measures have proved of only temporary value the results have merited the careful study of epidemiologists elsewhere.

In such an isolated and sparsely populated country an invading germ can be followed almost visually, as it passes from one lone farmstead to another, and it is subject to an attention as disconcerting and personal as that which would be bestowed on a foreign burglar misguided enough to choose Iceland for his field of operations. So much for the geographical character of the country which makes it so helpfully transparent in the eyes of the epidemiologist. It is transparent in another sense. In the crowded, patchwork civilisations of other countries it is a wise man who knows his own father, and a clairvoyant who knows his own grandfathers. But in Iceland everyone can follow his ancestry back a thousand years. Think what this must mean to the student of the problems of heredity! The country is transparent not only geographically and contemporaneously but also historically.

Iceland's comparative isolation for 1000 years has provided a vast mass of material for the study of environment as well as of heredity. The sheep brought over by the early Norwegian settlers differ in certain respects from the sheep in Norway to-day, and it is possible that the descendants of the settlers themselves have developed on lines not altogether identical with those followed on the Scandinavian mainland. Here again there is a very interesting field of study awaiting the anthropologist. Prof. Hannesson's anthropological studies have already blazed a track in this hitherto almost unexplored sphere.

There are many striking differences in the behaviour of certain diseases in Iceland and other countries. A study of these differences might well throw important light on the ætiology of these diseases. It is easy enough to understand why the bacillus of leprosy and the echinococcus should have been comparatively common in Iceland up to the end of the last century. But the country's remarkable immunity to certain other diseases, which are relatively common elsewhere, is to a large extent an unsolved problem. Why should acute rheumatism run so mild a course and the cardiac complications thereof be so infrequent? Why should diabetes be almost unknown, and cancer of the uterus so rare? Why should cerebral apoplexy be so common in the almost complete absence of syphilis? Why should this accident apparently run in families? The prospect of answers being found to these and other questions is enhanced by the high standard of the medical profession in Iceland and by its intimate and steadily growing contact with medical science abroad. Were this contact to be promoted by every possible means I am sure that the accruing benefit would not be one-sided. Iceland should prove a happy hunting ground for research workers, not only for the reasons already given, but also because the Icelandic medical profession receives the medical stranger within its gates with a most charming and spontaneous hospitality.

My most grateful thanks are due to Prof. Gudmundur Thoroddsen, Dr. Olafur O. Larusson, of the Vestmanöy Islands, and Dr. Gunnlaugur Claessen for the help they gave me.

THE EFFECT OF TOXÆMIA ON THE FORMATION OF ENAMEL.

HYPOPLASIA of the dental enamel, characterised by a honeycombed or pitted condition of this tissue, is comparatively common. It has long been recognised that it is often due to some disease or metabolic disturbance during the period of calcification, the subsequent eruption of the affected teeth remaining a permanent record of a past defect in nutrition. Hypoplastic teeth are still sometimes termed rachitic teeth on the supposition that rickets is the chief disease resulting in enamel defect. We know now that while rickets often brings about defective calcification, other diseases also, especially the infective diseases of childhood, may leave their mark on the teeth. Since the dates of calcification are known, the observer can usually predict with tolerable accuracy the times when the disturbance in nutrition affected the portion of the enamel defectively formed.

Dr. L. B. Stott and Mr. W. B. Grandison have investigated the occurrence of dental hypoplasia in children at the Papworth Village Settlement, and their results have been published in an attractively produced monograph.[1] They have been struck by the fact that during dental inspection of the children at this Settlement some showed perfect dentitions, while their general condition and personal hygiene did not differ from that of sufferers from varying degrees of dental caries. This has led them to examine the dental and medical records with a view to ascertaining the significance of this apparent immunity from dental disease. The correlation of the medical and dental records leads them to the view that infective disease during calcification produces hypoplasia while, as a necessary corollary to this, they suggest that acquired resistance to infectious disease is followed by satisfactory calcification.

The interesting suggestion is made that the calcium metabolism in the teeth follows those variations in the calcium metabolism of the body as a whole which occur in active tuberculosis and its arrest. In active tubercle the calcium excretion is high, so the teeth in process of calcification do not receive enough lime salts and are therefore defectively formed. When tuberculosis is arrested the process is characterised by the deposition of calcium in the tuberculous foci. Thus deposition of calcium is a tissue action which may be widespread in and is associated with a low calcium excretion. Hence it might follow that in cases of acquired immunity the teeth undergoing calcification receive plenty of calcium and are, in consequence, highly calcified and resistant to caries.

A further point of some theoretical importance raised by Stott and Grandison is whether this power of depositing calcium is part of a natural resistance or whether it is increased by exposure to infection and is thus due to acquired immunity. They suggest—though they do not bring much evidence to support the suggestion—that efficient calcification is conferred by acquired rather than natural immunity. This seems to mean that the dental enamel is more highly calcified in children who have been exposed to infection, which they have subsequently overcome successfully, than in children who have escaped exposure to infection altogether. The logical and somewhat surprising outcome is that immunity to dental caries, instead of being a function of a normal calcium metabolism leading to normally formed enamel, is rather a function of an abnormal calcium metabolism which causes excessive calcification of the enamel.

THE FUTURE OF MONOGAMY.

A PROPHECY that the years 1930 to 1975 will be a period of sexual reform, during which the institution of monogamy will undergo vicissitudes consequent upon the universal teaching of sex hygiene and the liberation of marriage from external inhibitions, is made in an addition to the To-day and To-morrow Series, which has reached us.[2] The period 2000 to 2030, however, will see the triumph of voluntary monogamy. The somewhat startling reason for this is that "no type of union has yet been discovered in which the maximum of intellectual variety may be so effectually combined with the minimum of emotional disturbance." The book is written in the form of a chapter out of a hypothetical history of moral institutions in the nineteenth, twentieth, and twenty-first centuries. The contemporary literature on which the survey is based is not representative, the chief sources being the series in which this book appears. In the course of the next hundred years, the author thinks, the institution of monogamy will have completed a circle, ending up much as it is now, except that it will be voluntary instead of compulsory, and based on sexual knowledge instead of upon ignorance. The psychological presupposition of this desirable change is that confidence will be gained in humanity's ability to impose voluntary restraints upon its conduct. No attempt whatever is made to analyse the growth of these morally inhibiting processes, and the relevant psychological literature is nowhere referred to.

MEDICAL MISSIONS.

A LITTLE book called "The Touch of Healing," by M. M. Wood,[1] will be welcomed by anyone who wishes to give young people a vivid description of medical missionary work. It is attractively written and illustrated, and is full of arresting anecdotes, drawn from every corner of the world where missionary work is carried on. The photographs come from India, China, Egypt, and Palestine. The training and work of a missionary nurse is sketched out, and the treatment—often in bulk—of all kinds of tropical disease is described. The value of medical missions is undisputed, and the tales in this book show how western science is appreciated by the races to whom it is taken by these devoted men and women.

CASH BEFORE NON-DELIVERY.

M. R. D. (Wembley) has received a call from a man desirous of obtaining orders for printing, corks, bottles, and the like, who presents as his credential the card of a professional colleague. After receiving payment in advance, nothing more is heard of him. Obviously any instances of frauds of this nature should be promptly reported to the police, in order to teach a lesson to the unscrupulous persons who seek to victimise medical practitioners. The number of these is large, partly because they can so easily obtain an interview, partly, one fears, because practitioners are regarded as readily imposed upon. We would once again warn members of the medical profession to be on their guard against dealing with persons who are entirely unknown to them, with a special caution against making cash payments for goods prior to delivery.

A NURSE'S SALARY DURING ILLNESS.

A. L. M.—The payment of salary during the illness of a nurse is a matter of usage rather than of obligation. The usual practice, both in institutions and on the district, is to pay full salary during sickness for a period dependent upon the length of service the nurse has rendered. Most institutions would retain her national insurance benefit, but some district nursing associations allow a nurse who has been in their service for some time, and who is not well off financially, to retain her benefit for a period. One well-known nursing institute is considering the equity of recommending full salary and allowance for board for six weeks, and after that half the amount. The private nurse must, unfortunately, make her own provision for sickness; but hospitals will often give her free accommodation and care.

DANGEROUS DRUG RECORDS.

H. E. S.—A duly qualified medical practitioner is "authorised" to be in possession of dangerous drugs and to apply them by personal administration. In purchasing the drugs he is subject to the conditions of the Pharmacy Acts relating to the sale of poisons—e.g., signing the poison-book, and so forth. If the practitioner requires the drugs solely for administration to his patients by himself personally, or under his own direct supervision, he is under no obligation to keep the records required by the Regulations in the case of dispensing doctors. If, on the other hand, he dispenses or supplies medicine (which the Home Office interprets as including the case of a doctor leaving a supply of any of the drugs with a nurse for administration to a patient during the doctor's absence), he must keep the prescribed registers.

THE British Social Hygiene Council would be glad to hear from medical men and women willing to give single lectures in London or to undertake short campaigns in the provinces. The fee for a single lecture in London is 1 guinea. Application to the Secretary-General of the Council, Carteret House, Carteret-street, London, S.W. 1.

Murphy Oration

ON SOME PRINCIPLES IN ABDOMINAL SURGERY.

Delivered at the Clinical Congress of the American College of Surgeons, at Chicago, on Oct. 14th, 1929,

BY D. P. D. WILKIE, O.B.E., M.D., F.R.C.S. EDIN.,
F.R.C.S. ENG.,
HONORARY FELLOW OF THE COLLEGE; SURGEON TO THE EDINBURGH ROYAL INFIRMARY; AND PROFESSOR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.

THE capacity of the peritoneum and the abdominal viscera to tolerate even gross interference has been fully tested during the past 50 years and has formed the basis and the backbone of modern surgery. So great is that tolerance that we as surgeons are apt to presume on it and to lose that sense of reverence for living tissues which should be a fundamental law in operative surgery. By an elaborate ritual we endeavour to ensure that our operations shall be aseptic; but ritual without reverence may be a mockery, and technique associated with trauma will be tolerated less well than much less perfect asepsis but gentle handling. If we had to epitomise our guiding rules in the surgery of the abdomen, I believe we might correctly do so by stating "no traction, no tension." The primary impression conveyed to the mind at the first sight of the interior of a normal abdomen is the remarkable flaccidity of all the hollow viscera; *in quietness and in relaxation lies their strength.* When disease or operative measures interfere with this relaxation and introduce tension, trouble and pain result. Our guiding principle thus will be to relieve tension when we find it, and so to plan our operative work that neither during nor after the operation shall tension on the abdominal wall, the viscera, or the mesenteries be present.

The signal advances in our standard of preoperative diagnosis has furnished us with the advantage of being able so to plan our incisions in the abdominal wall that we shall have the freest possible access to the seat of disease without recourse to forcible retraction. Whilst the integrity of the abdominal muscles and their nerves will ever command our respect adequate access must always be the first consideration in any major abdominal operation. Too small boots *beget corns; too small incisions beget complications.* If we visualise the tissues as living, delicate cellular structures we become less and less intrigued with elaborate mechanical appliances, such as powerful self-retaining retractors and mighty crushing clamps, instruments which not only injure directly the patient's tissues, but blunt obliquely the surgeon's sensitivity. Retractors should be used to retain out of the surgeon's way tissues which have been gently pushed aside—too often we have seen them used as if they were weapons.

THE PRINCIPLE OF DE-TENSION.

It is in the effective mobilisation of the tissues to be dealt with that our text is best illustrated. Deal only with the mobile organ; if it be immobile, mobilise it. Do it not by force but by strategy based *on the anatomical fact that all the abdominal organs* were mobile before some became fixed, and therefore all may again be rendered mobile. This sounds dangerously like a platitude and yet this rule is but imperfectly observed, and what should be easy and safe surgery is often rendered difficult for the surgeon and dangerous for the patient.

When William Mayo demonstrated so beautifully how a generous mobilisation of the proximal colon might be effected so as to render resection of a large segment both simple and safe, he illustrated a principle which has a widespread application in the abdomen. Other portions of the gut, such as the duodenum, the splenic flexure, and the descending and iliac portions of the colon, are equally susceptible of mobilisation. How often can a resection of the transverse or distal parts of the colon be rendered easy by a simple division of the phrenicocolic ligament when tissues, which would otherwise be united under tension—that unforgivable sin in abdominal surgery—will fall together in perfect relaxation. In the mobilisation of organs there are two structures to be divided, the peritoneal folds which retain them, and the underlying, and in the case of diseased organs usually thickened, extraperitoneal cellular tissue, or, as we usually designate it, the "fascia propria." It is the division of this fascial layer which renders the mobilisation complete, and this division can best be effected by the knife. Thus we find in the mobilisation of the duodenum a simple division of the peritoneum along its lateral border will free it considerably, but *it is only when we divide the fascial bands which hold* it, and especially its inferior border, that it can be brought up freely into the abdominal wound. In the case of the colon the systematic division of the extraperitoneal fascial bands by the knife is of equal advantage.

In one operation above all others, however, is this principle seen to greatest advantage—namely, in splenectomy. The greatest impediment to removal of the enlarged spleen is in my experience not inflammatory adhesions, which are rare, but the short outer leaf of the lieno-renal ligament. Without an adequate severance of the ligament the spleen cannot be delivered except at the imminent risk of a tear in the hilum. Not only must the peritoneum on the outer side of the splenic pedicle be divided but also the underlying fascia. Thereafter a spleen which was apparently fixed, *so as almost to defy safe removal,* comes forward into a field where easy control of the pedicle is readily secured.

Even when we consider such a simple operation as removal of the vermiform appendix we find that the usual impediment to easy removal is not the presence of inflammatory adhesions but the binding down of the middle third *of the organ by that congenital fold,* first described by Douglas Reid as the genito-mesenteric fold. This fold is practically bloodless, and a few touches of the knife, dividing it, will mobilise the appendix completely and allow it to come up without tension into the abdominal wound.

MOBILISATION OF VISCERAL COATS.

When a portion of the gastro-intestinal tract is resected, union, whether by end-to-end suture or by lateral anastomosis *after closure of the ends, must be* effected. When Murphy introduced his button he did a great service to surgery, not only by evolving an ingenious instrument which has stood surgeons in good *stead on many occasions* when ordinary suture methods were impracticable, but mainly by proving that if accurate peritoneal apposition was obtained, elaborate layers of suturing were quite unnecessary.

Whilst leak from a suture line may be referable in some cases to sepsis, in others to inadequate blood-supply, it is in my opinion usually due to tension either in the long axis of the gut, due to inadequate mobilisation, to tension in the suture line, or to postoperative tension within the lumen of the gut. If free mobilisation of the ends to be joined has been effected, I believe that in the principle of mobilising the coats of the viscera to be joined so that the layers *may be sutured* together without any undue tension lies the secret of safe anastomosis. When we remember that the peritoneal and muscular coats of the hollow viscera offer but a slender hold for sutures, that the strength of the wall in every case lies in the submucous coat, we realise that safe approximation of the outer coats can only be accomplished if carried out with these coats completely relaxed. Such relaxation can only be secured, and this particularly in the colon, if these are first divided down to the submucous layer in each end of the bowel entering into the anastomosis. In the colon it is the longitudinal muscular bands which, being shorter than

THE PRINCIPLE OF REPLENISHING PHYSIOLOGICAL LACK.

The cause of death in high intestinal obstruction is a subject which has attracted the intensive interest both of practical surgeons and laboratory workers. Gradually the factors which are operative in producing the condition of collapse, so characteristic of this type of obstruction, have been elucidated, and whilst much remains to be cleared up we have to-day in our possession a number of facts which point the way to ultimate solution of this difficult problem. Whilst doubtless a chemical substance of albumose type is absorbed from the distended bowel above the obstruction, and whilst drainage of this obstructed gut will give some relief, we know that death may yet ensue when free drainage is established. The pronounced dehydration which accompanies such obstruction and the call of the tissues for fluid is now recognised to be of primary importance and replenishment of body fluids the first indication in treatment. The very important fact that a notable and dangerous loss of chlorides occurs in such cases has led to the use of hypertonic saline injections with marked improvement in results. The aspect which I wish to emphasise, however, is that of the secretions which should normally descend into it from the upper portion.

We know that in animal experiments high obstruction with immediate drainage of the bowel is not survived for very much longer than an obstruction without drainage. The fluid, which in the bowel above the obstruction may appear to be toxic and threatening the patient's life, may be life-saving if introduced into the bowel below the obstruction. This fact was first borne in on me by a case of post-operative obstruction following acute appendicitis which is recorded in the *British Journal of Surgery* (1924, xi., 568), but to which I venture again to refer here.

In this case an enterostomy was performed but the coil opened was evidently below the really active obstruction, for no flow from the tube resulted. Later on the same day a second enterostomy was performed, this time on the highest jejunal coil, and a profuse discharge followed. In spite of copious saline infusion the patient continued to go downhill until the device of joining up the two enterostomy tubes was practised, when the abundant secretions from above the obstruction were conducted through the joined tubes to the intestine below. An immediate and remarkable improvement followed this manœuvre, and the patient made a satisfactory recovery and is alive and well to-day.

This call of deprivation of the empty intestine below in cases of high obstruction constitutes, I believe, an important principle in the treatment of such cases. R. St. L. Brockman has emphasised the benefit of enemata of bile in post-operative ileus, and has shown the important rôle which the absorption of bile from the lower reaches of the bowel has in liver function. There are, I believe, other factors besides bile in the profound physiological upset which results when an obstruction occurs between the active secretory upper part of the small intestine and the absorptive reaches below. The emptying of the upper distended coils at operation for acute obstruction of the small intestine, say from a band, may by reducing intra-abdominal tension permit of more vigorous peristalsis thereafter and thus be an advantage. It will not save the patient's life, however, unless subsequent peristalsis results in the propulsion of the content of the higher coils into the empty coils below. The conception of a physiological lack below, combined with a pathological retention above, is one which deserves our attention and will find a field for application in our practice.

CLAPHAM MATERNITY HOSPITAL.—This hospital, in Jeffrey's-road, London, S.W., which is staffed by medical women, is giving free training in midwifery to six daughters of unemployed Welsh miners. Last year, the annual report states, there were 708 maternity in-patients, 109 more than in 1927; 458 out-patients were attended in their own homes.

SYPHILITIC DISEASE OF THE PULMONARY ARTERIES,

WITH ACCOUNT OF A CASE.

By DOROTHY C. HARE, C.B.E., M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL FREE HOSPITAL;
AND
JOAN M. ROSS, M.D. LOND.,
SENIOR ASSISTANT PATHOLOGIST AND LECTURER IN PATHOLOGY TO THE HOSPITAL.

ANY case of arterial disease affecting the lesser circuit merits careful investigation because of the light it may throw on the problem of systemic arterial hypertrophy and degeneration.

In extreme cases of high pressure on the right side due to valvular disease of the heart, chronic bronchitis, and emphysema, &c., "the pulmonary artery suffers strain and injury more commonly than is supposed" (Allbutt [1]). The atheroma which may follow is, in Marchand's opinion, a crucial instance of atheroma due to high blood pressure. Posselt [2] (1909) was one of the first to point out that pulmonary atheroma arising as a result of chronic valvular disease of the heart could be held responsible for a definite clinical syndrome. Rogers,[3] in the same year, published the first account in this country of a similar clinical syndrome observed in Bengal, occurring in cases of syphilitic arterial disease affecting the vessels of the lesser circuit and independent of any valvular disease of the heart or chronic pulmonary condition. The next period of interest in diseases of the pulmonary arteries followed the publication (in the Argentine) of observations by Ayerza and by Arrillaga.[4] Following a more or less prolonged period of chronic pulmonary disease the Argentine cases developed cardiac symptoms with intense cyanosis (cardiacos negros) with dyspnœa, hæmoptysis, somnolence, and polycythæmia. These cases showed dilatation and disease of the pulmonary artery with extreme hypertrophy and dilatation of the right heart. Escudero[5] considered these cases as examples of pulmonary arteritis consecutive to syphilitic bronchitis. Veale and Coombs,[6] in 1915, in this country, and Mattirolo[7] and Gamna,[8] in 1921, in Italy, made other observations of importance, describing cases in which there was no evidence of syphilis, and no antecedent pulmonary or cardiac lesion responsible for the changes in the pulmonary artery. They established the existence (in a small number of cases) of a primary form of disease of the pulmonary artery.

Since this date there have been scattered references to the condition in the literature of nearly all countries. In France especially there has been increasing interest both in the primary (Durand,[9] 1927) and in the syphilitic form (Laubry and Thomas, Caussade and Tardieu, Darré and Albot, Trémolière, Tardieu, and Nativelle). In Italy Benedetto and de Castro [10] have published a comprehensive review (1928). In America (Bruce and Wilson, Bacon and Apfelbach) cases of the primary lesion have been described, and four cases of the syphilitic form have been published. (Cheney, Bruce and Wilson, Wharthin, Zeman).

That the syphilitic form of the disease is much the most common becomes a matter of importance when the symptomatology of the disease is considered. For, although syphilis is recognised in sanatorium practice as one cause of a destructive lesion of the lung simulating chronic ulcerative phthisis, it is not so frequently realised in out-patient practice that the *Spirochæta pallida* may also be responsible for a clinical state closely resembling chronic bronchitis and emphysema and usually diagnosed as such, while actually due to widespread endarteritis and periarteritis of the branches of the pulmonary artery.

Report of the Case.

The patient was a male house-porter aged 47. Previous army service for 14 years. Discharged in 1916 with tabes.

Possibly gassed, but army pension refused on ground of syphilitic infection. Mother had died of consumption.

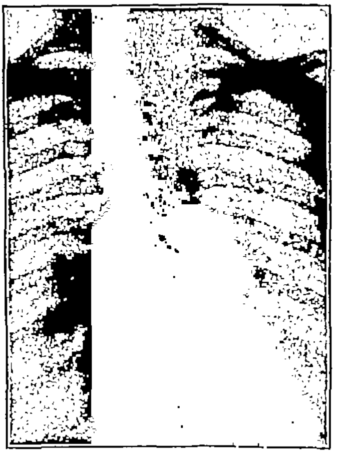
History.—Three years before the final illness he had attacks of giddiness and fainting; he fell down several times while at work. In the following year he had "bronchial asthma," and afterwards was unable to work, owing to breathlessness on exertion. Next year he had only one attack of faintness, but much discomfort from flatulence. He was in bed for six weeks before admission with œdema of legs during last three weeks.

Condition on Admission.—Admitted to Royal Free Hospital on Nov. 10th, 1928; he was in a distressed, dyspnœic condition, much cyanosed; pulse-rate 92, respirations 28. Venesection was performed a few hours later, the distress passed off gradually during first 24 hours, and no such acute attack recurred. Cyanosis of face and hands was present, but not extreme. No finger clubbing. Trunk was thin and there was a moderate degree of œdema of the legs, thighs, lower abdomen, and lumbar region.

He complained of sense of oppression over chest. Morning cough was infrequent and not paroxysmal; the sputum scanty, opaque, and muco-purulent. No tubercle bacilli were found. Respiratory movements were very poor, of diaphragmatic type, rate 20 to 24. The percussion note was not impaired; breath sounds were very weak, but otherwise normal. There were generalised sibilant and sonorous rhonchi. The heart was enlarged, but præcordial dullness could not be defined, owing to emphysema. The pulmonary second sound was accentuated and reduplicated. The pulse was of good volume and regular. The blood pressure was systolic 140, diastolic 110. He complained also of "flatulence." The bowels were regular. The abdomen was distended and rigid, with a small amount of free fluid. Palpation was difficult, but the liver was found to be enlarged to umbilicus, smooth, and not tender. The spleen was not palpable at any time.

A further complaint was of hesitancy on micturition and decrease in amount of urine. In hospital the amount of urine passed daily was 30 to 40 oz., with no albumin or other abnormality.

FIG. 1.



Skiagram showing bulging of the middle arc of the cardiac shadow.

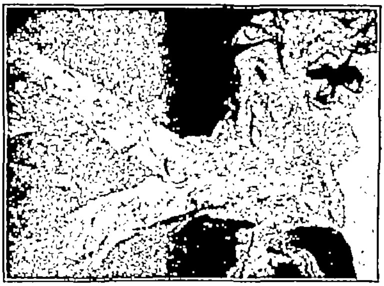
The pupils were irregular and unequal, and did not react to light. Knee- and ankle-jerks were absent.

Blood.—The Wassermann reaction (blood) was very slightly positive. The cerebro-spinal fluid was not examined. On Dec. 3rd the blood showed red blood cells 6,180,000 per c.mm.; hæmoglobin, 90 per cent.; colour-index, 0·75; white cells, 6900 per c.mm.

Electrocardiogram.—Report by Dr. Jenner Hoskin. Rate 76, regular. Marked right preponderance. T_1 adequate, T_2 and T_3 inverted. P_2 and P_3 large, suggesting auricular hypertrophy. Indicates changes in region of aortic base, at present right ventricle working adequately. (Nov. 20th, 1928.)

Skiagram (Fig. 1).—The following report was made by Dr. Ulysses Williams: "Generalised emphysema of moderate intensity, and distributed fairly uniformly throughout both lungs, more marked at the bases, especially the right. The interstitial fibrous tissue is about normal for a man of this age. Great enlargement of the first part of the pulmonary artery, and owing to the great hypertrophy of the right ventricle, and the rotation to the left of the whole heart, the base of the pulmonary shows more than usual."

FIG. 2.



Left lung. Arteries laid open to show atheromatosis.

Course.—The outstanding symptoms were attacks of great abdominal discomfort, described by the patient as due to flatulence, with tightness of the chest; usually nocturnal, preventing sleep. There was definite improvement for first four weeks. The liver shrank, the circumference of the abdomen fell from 35 in. to 31 in., the œdema disappeared. Later these symptoms, together with almost complete anorexia, reappeared. *The liver increased in size, forming a* prominence in the epigastrium. Some epigastric pulsation was present. A coarse systolic murmur, probably exocardial in origin, developed over the lower end of the sternum. The heart gradually failed, sleep became more disturbed, and the patient died on Jan. 10th, 1929, two months after admission.

Post-mortem Examination.

Externally considerable œdema of lower limbs, cyanosis of face, cyanosis of ears striking.

Thorax.—Universal pleural adhesions which separated with difficulty. Pericardial cavity contained a slight excess of fluid. Coronary sinus not abnormal in size. Visceral pericardium white and opaque over anterior surface of right ventricle and over whole of right auricle.

Lungs.—Somewhat deformed. Hard nodules palpable in subpleural tissue and in the substance of the lungs. Pleuræ thickened. On section, upper lobes extreme emphysema, fibrous nodules inconspicuous, lower lobes less emphysema, nodular fibrosis widespread. Fibrosis marked towards root of lungs here in form of strands of fibrous tissue rather than nodules. Intrapulmonary branches of pulmonary artery showed dilatation and numerous yellow intimal plaques of atheroma. These could be seen in all vessels down to those of 3 mm. *in diameter (Figs. 2 and 3).* The bronchi showed no gross change.

Heart.—Externally enlarged. Right ventricle lay entirely in front of left, forming apex of heart.

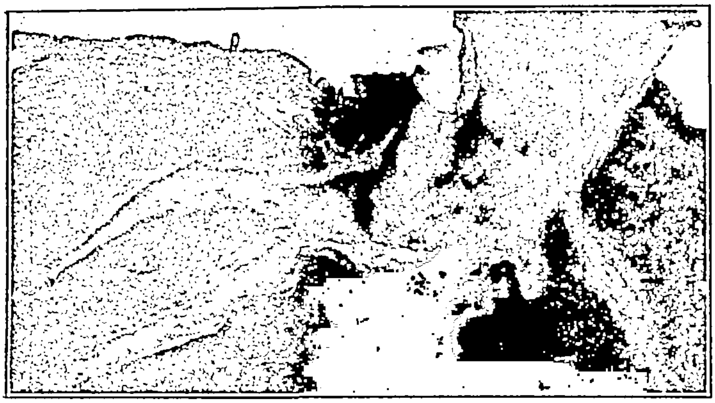
	Right Heart.	*Left Heart.*
Cavities.. ..	Greatly dilated ..	Normal.
Valves	Tricuspid normal .. Pulmonary " ..	Mitral normal. Aortic "
Myocardium ..	Firm and dark ..	Brownish in colour. Some subendocardial fibrosis.
Ventricle wall: thickness at apex.	9 mm. (Normal, *2·5–3 mm.)*	12 mm. (Normal, *9–12 mm.).*
Circumference at orifice.	Pulmonary 9·35 cm. (Normal 8·5–9 cm.)	Aortic 6·75 cm. (Normal 7·7–8cm.)

Ratio of circumference of pulmonary artery to that of aortic, 1·38. Normal, 1·1.

Coronary vessels: Normal.

Aorta.—First part of arch and upper half of the thoracic aorta showed considerable change. Intima, irregular pitting and depressions, some stellate. Pearly-white scarring. Also yellowish raised patches with calcification and, in first part, some ulceration. Changes became less severe and terminated somewhat abruptly about halfway down the thoracic vessel. The appearances suggested syphilitic mesaortitis with superimposed atheroma. The abdominal aorta showed no change, nor did the vessels of spleen, liver, and kidneys show any abnormality.

FIG. 3.



Right lung. Arteries laid open. The walls of the vessels are thickened, their course tortuous; the atheroma is more severe in the smaller vessels.

Pulmonary Artery.—Main vessel. Lumen dilated, some slight thickening of walls. Intima, no naked-eye changes. Main branches, some intimal change, but no large patches of atheroma till the root of the lung was reached (Figs. 2 and 3).

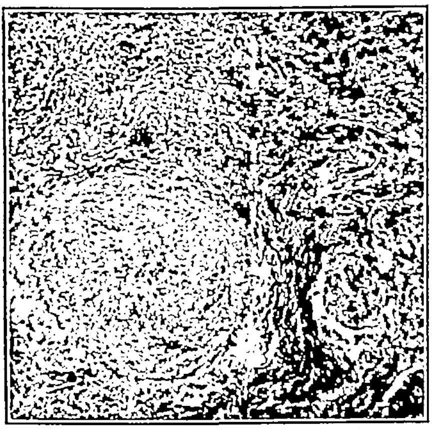
Spinal Cord.—Naked-eye and microscopic changes typical of tabes. Pal-Weigert preparations showed symmetrical degeneration in posterior columns.

The other viscera showed no changes of any importance except those due to congestive heart failure.

Histopathology.

The *aorta* showed vascular invasion of the media with accompanying lymphocytic and plasma cell infiltration typical of syphilis, and a superadded atheroma and some calcification.

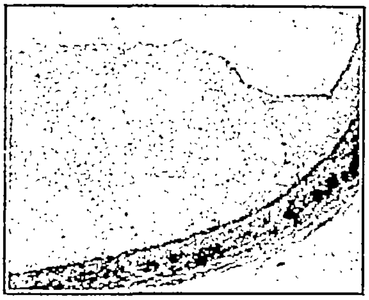
FIG. 5.



Artery in substance of lung showing extreme obliterative endarteritis, perivascular fibrosis with carbon deposit, and some infiltration by lymphocytes and plasma cells.

Pulmonary Artery.—(1) Vessels over 3 mm. in diameter: The main vessel had slight thickening of its walls, mainly due to increase of thickness of the strong band of elastic tissue visible in longitudinal section. The elastic tissue of the outer part of media was increased in amount, but here showed localised fibrous tissue areas. The intima, even in areas which appeared normal to the naked eye, showed some increase in fibrous tissue. The right and left pulmonaries and their larger branches showed atheroma without calcium deposit. There was no evidence of any inflammatory change (Figs. 2, 3, 4). (2) Vessels about the diameter of 3 mm.: Some of these showed invasion of their walls by lymphocytes and plasma cells. Atheroma present at the same time. There was periarterial fibrosis. (3) Vessels smaller than 3 mm.: The change was severe and took the form of a chronic panarteritis. In some of the vessels (Figs. 5 and 6) the lumen was almost obliterated owing to proliferation of the intima. In vessels lying near the more cellular areas of fibrosis the arteritis was subacute and some plasma cells and lymphocytes were present in the wall.

FIG. 4.



Right pulmonary artery. Longitudinal section through a plaque of atheroma.

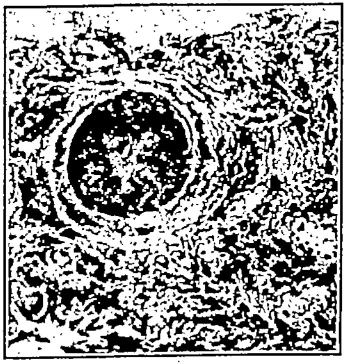
Lung: Fibrous Nodules.—Occasionally truly perivascular, the vessel lying in the centre of the nodule. More often the nodules lie near the vessels. In the subpleural region these nodules were vascular and showed a considerable amount of cellular infiltration (Fig. 7), and, since they contained elastic tissue deposed more or less regularly throughout, they may be supposed to have arisen by the obliteration of alveoli. There was a carbon deposit. Some of the nodules in the substance of the lung contained numerous lymphocytes and plasma cells, with an occasional giant cell.

Alveoli.—The changes in the alveoli in the neighbourhood of the sclerotic patches were: (*a*) proliferative. The alveolar lining cells were cubical and in places filled the entire lumen. Macrophages, laden with brown pigment, were present in large numbers (Fig. 8); (*b*) obliterative. Plasma cell and lymphocytic infiltration and, later, a development of collagenous connective tissue.

In other parts of the lung high-grade emphysema was present.

Bronchi.—The changes in the bronchi were relatively slight and of the nature of a compression rather than actual involvement in the inflammatory process. In some bronchioles involved in the sclerosis of the lung parenchyma the epithelium showed squamous metaplasia.

FIG. 6.



Subpleural arteriole, showing almost complete obliteration of lumen.

Clinical Summary.

Twelve years' history of tabes dorsalis. Blood Wassermann slight positive. Two years' severe progressive dyspnœa, accompanied by asthma and cyanosis. A few weeks' œdema of legs. Progressive right heart failure with regular pulse.

Summary of Post-mortem Examination.

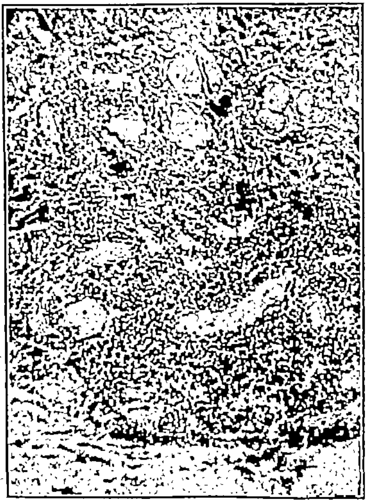
1. Chronic bilateral pleurisy with dense universal adhesion. 2. Chronic vesicular emphysema. 3. Diffuse and nodular fibrosis of both lungs, equal in the two sides. Emphysema of high grade in both upper lobes

and here fibrosis inconspicuous. Fibrosis marked at the roots and in lower lobes and here emphysema less. Nodular fibrosis present throughout both lungs, both subpleural and in their substance. 4. Marked hypertrophy and dilatation of the right heart. 5. Universal atheromatosis of the main right and left pulmonary arteries and their larger branches. Main vessel spared. 6. Widespread periarteritis and obliterating endarteritis of intrapulmonary branches of the pulmonary arteries; severe and accompanied by periarterial inflammatory changes in almost all vessels from 3 mm. diameter to precapillaries. 7. Mesaortitis and atheromatosis of thoracic aorta. 8. Degeneration of the posterior column of the spinal cord. 9. Chronic venous congestion of viscera.

Review of Cases.

Vaquez[11] has suggested the division of cases of sclerosis of the pulmonary arteries into two broad groups, "sclérose complication" and "sclérose maladie." In the first group the changes in the pulmonary artery arise as a complication of some antecedent cardiac or pulmonary condition and the clinical signs and symptoms of the underlying morbid changes are usually apparent. In the second group (and it is to this group that the present case belongs) the signs and symptoms are those due to or consecutive to the alterations in the pulmonary vessels themselves. That this second group does not consist of cases having a common ætiological basis is clear from the scrutiny of the published cases in the recent literature.

FIG. 7.

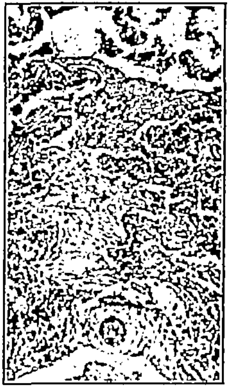


Section of subpleural fibrous nodule, showing new formation of vessels, carbon deposit, numerous lymphocytes, and plasma cells.

In reviewing these cases of arterial disease, confined or largely confined to the pulmonary circuit, it is proposed to disregard those cases with no post-mortem and those in which no exact pathological (based on histological evidence) diagnosis is possible. Only cases in Vaquez's second group will be considered. That such a restriction curtails the number of cases reviewed is obvious and some series of cases, notably five cases reported by Eppinger and Wagner,[12] are omitted on the grounds of inadequate histological reports.

It will be seen that among the collected cases many are syphilitic in origin. The diagnosis of syphilis has rested upon (1) the Wassermann reaction; (2) the presence of other stigmata of syphilis, especially aortitis; (3) the histological changes in the pulmonary vessels and in the lung itself. The final decision for or against syphilis rests upon the histological examination of the pulmonary vessels.

FIG. 8.



Proliferative changes in alveoli at the margin of a fibrous nodule.

Wassermann Positive or Strongly Positive (11 Cases).—All showed syphilitic arteritis of small pulmonary vessels. In addition aortitis in six cases (Nos. 6, 8, 10, 16, 17, 24). Arteritis of main pulmonary in ten cases (Nos. 2, 6, 8, 10, 12, 13, 14, 16, 17, 24). Tabes dorsalis in one case (No. 10). Alveolar lesions in three cases (Nos. 2, 10, 24).

Wassermann Very Slightly Positive (2 Cases).—One showed syphilitic arteritis of small pulmonary vessels and in addition aortitis, tabes dorsalis, alveolar lesions (No. 1). One showed no other evidence of syphilis, and the vascular lesions were non-inflammatory (No. 4).

Table of Collected Cases of Acquired Disease of the Pulmonary Artery.

Dbt. = doubtful.

N.B.—In referring to these cases in the text the number in the left-hand column will be quoted in brackets—e.g., (No. 11) refers to the case reported by Darré and Albot.

Wassermann Negative (3 *Cases*).—None showed any inflammatory element in the lesions of the pulmonary artery. Two showed no evidence of syphilis (Nos. 3 and 6). One had a definite history of syphilis (No. 10).

Wassermann, no Record (8 *Cases*).—Four cases showed arteritis of the small pulmonary vessels (Nos. 7, 11, 21, 23). In addition: aortitis (Nos. 11, 23). Arteritis main pulmonary (Nos. 11, 23). Alveolar lesions (Nos. 7, 11, 21). One case showed arteritis consecutive to typhus (No. 20). Three cases showed non-inflammatory lesions of the pulmonary vessels. No ætiological factor (No. 9). History of syphilis and bronchitis (No. 18). Congenital stenosis of pulmonary veins (No. 22).

The total number of cases under review is 24, and they may be divided into the following groups: (1) 16 diagnosed as having a syphilitic basis; (2) two in syphilitics with non-specific histology of arteries; (3) one following typhus; and (4) five diagnosed as primary. The average age of syphilitics is 47·8, of the primary cases 21, and of those in groups (2) and (4) 27·5. In groups (2) and (4) combined the oldest case (49) had a definite syphilitic history; the histology of the arteries was not diagnostic. None of the others was over 40. In group (1), in which the youngest was 29, only four were under 40.

We may draw two conclusions from these figures—viz., that syphilis is by far the more important ætiological factor in older patients, and that primary sclerosis of unknown ætiology is found in younger patients.

In the analysis of the post-mortem findings and the clinical signs and symptoms which follow reference is only made to the syphilitic cases.

Lesions in the Pulmonary Vessels and Lungs.

1. *Main Pulmonary Artery and Extrapulmonary Branches.*—Thomas[13] points out that, although the classical conception of the distribution of syphilitic vascular disease is that syphilis attacks the aorta, but respects the pulmonary circulation, in his series of cases there are numerous instances of both vessels being attacked. (Out of 10 cases showing arteritis of the pulmonary artery six had aortic lesions.) He shows that in some cases the aortic lesions are considerable, while the pulmonary artery is only mildly damaged, but that in other cases the alterations in the two vessels are of equal importance. Some of the cases described by Thomas are not included in the present series since the aortic lesion provides the clinical phenomena. Taking all the collected cases it is interesting to analyse the frequency with which syphilitic lesions of the main pulmonary vessels and syphilis of the aorta are associated with syphilitic arteritis of the smaller branches of the pulmonary artery. In 16 cases there was syphilitic arteritis of small pulmonary vessels:—

In 12 with main pulmonary and right and left pulmonary artery syphilitic: aorta syphilitic in 7, aorta normal in 5.

In two with main pulmonary and right and left pulmonary arteries, showing athero-sclerosis: aorta syphilitic in one; normal in one.

In two with main pulmonary and right and left pulmonary arteries, showing dilatation only; aorta normal in both.

These figures show that in syphilitics with an initial vascular lesion of the smaller pulmonary arteries the main pulmonary artery and its branches are more often (12 cases) affected than is the aorta (8 cases). The lesions in the large pulmonary vessels when purely syphilitic are similar to the classical picture of syphilitic mesaortitis due to syphilis. There is, in nearly all cases, superimposed athero-sclerosis. The vessel may be very greatly dilated. The ratio of the circumference of the pulmonary artery to that of the aorta is increased to 1·3 (No. 10), 1·38 (No. 1), 1·4 (No. 2), normal 1·1. In one case (No. 14) there was a saccular aneurysm of the pulmonary artery.

Thomas in his thesis states that the syphilitic lesions scattered and not intense in the trunk and great branches are more numerous and widespread in the branches at the hilum and in the medium and small branches; the majority of the collected cases show the same distribution. Trémolière, Tardieu, and Nativelle in their case, which also showed mitral stenosis, found the most severe lesions in the smaller vessels (about 5 mm. diam.) and in the trunk and first branches no longer specific panarteritis, but athero-sclerosis with atheroma (No. 21). The present case (No. 1) shows a similar distribution—whereas syphilitic arteritis was generalised throughout the intrapulmonary branches of the artery and most severe in the arterioles, the vessels at the hilum showed only slight inflammation with considerable athero-sclerosis and the trunk and first branches athero-sclerosis alone. Only one case in the series showed as healthy main pulmonary and healthy large branches (No. 7), the infundibulum of the artery alone showing dilatation.

2. *Intrapulmonary Vessels.*—All the cases show lesions in the intrapulmonary branches of the pulmonary artery. These lesions are more or less widespread (Nos. 11, 14), but tend to differ in severity and activity in the vessels of different calibre. In one case the lesions are stated to have been most severe in the vessels of the second and third degree (No. 23). In others the arterioles show the most extreme alterations (Nos. 1 and 10). The typical lesion is a panarteritis usually of a subacute form. All the vascular coats are altered and are infiltrated by plasma cells and lymphocytes with newly formed capillaries passing into the media and even to the intima (Thomas). The intima is thickened and the lumen may be partly or completely obliterated. Chronic panarteritis with periarterial fibrosis, with in some instances hyperplasia and in some cases destruction of the elastic tissue of the media (Thomas) may be present. Thrombosis occurs with considerable frequency. This may have been an incident during the course of the disease (Nos. 2, 7, 10, 21) or thrombosis with infarction of the lung may supervene without premonitory symptoms (No. 13). In some cases thrombosis has been followed by organisation with recanalisation, and a collateral circulation may have been established with a localised production of dilated blood-vessels (No. 2).

There is considerable uniformity in the vascular lesions throughout the series. Darré and Albot (No. 11) describe lesions which are identical with those in the present case. Trémolière, Tardieu and Nativelle and Thomas give valuable accounts of the vascular changes.

3. *Lung.*—Nearly all cases show the changes due to chronic congestion. Many cases show an extreme degree of emphysema (Nos. 1, 6, 8, 23, 24), in some there is a terminal œdema (Nos. 7, 13, 15, 21, 24), and infarcts of varying age were present in six cases (Nos. 11, 12, 13, 15, 16, 21). Lesions which can be truly referred to the results of syphilis are present in seven cases (Nos. 1, 2, 7, 10, 11, 21, 24). The changes take two forms: fibrosis spreading in broad bands throughout the lung and having origin in the dense fibrous tissue around the vessels (No. 10), and nodular areas of fibrosis.

The origin of the nodular areas of fibrosis may be interstitial or intra-alveolar. The interstitial nodules arise by organisation of perivascular or subpleural foci of lymphocytic infiltration. Such foci were described by Letulle and Dalsace[14] under the title of nodular cortico pleuritis, as one of the forms of latent syphilis of the lung reported by those authors. In later stages these foci become fibrous and often very vascular (Nos. 1, 7, 11). The intra-alveolar origin of fibrous tissue is described by French authors as "alveolite végétante." Alveoli or groups of alveoli become airless and filled with desquamated cells, many of which are loaded with brown pigment. Some mononuclear cells are also present. There is proliferation of the alveolar epithelium which has become cubical. Later the cells disappear and collagenous fibres take their place. Pigment may remain among the fibres. In sections stained with Weigert's elastic stain the remains of the alveolar walls can be made out in the resultant fibrous nodule (Nos. 1, 7, 11). In some cases true miliary gummatous foci are described (Nos. 1, 2, 21).

4. *Bronchi.*—The changes in the bronchi are slight in nearly all cases. Some catarrhal inflammation is reported (Nos. 8, 10) and some epithelial metaplasia (Nos. 1, 11). In one case only is there any evidence of the bronchial lesion being syphilitic and antecedent to or of the same age as the arterial lesion (No. 15). In reporting this case Thomas describes it as being a case of syphilitic arteritis arising in the course of bronchial syphilis, and therefore comparable to the cases described as "Ayerza's disease" by Escudero.

Changes in the Heart and Other Organs.

Two of the cases in this series had some degree of mitral stenosis (Nos. 7 and 21). None of the others showed any valvular disease. The characteristic change in the heart is great hypertrophy and dilatation of the right side of the heart. The right ventricle forms the whole anterior surface and the apex of the heart (Nos. 1, 2, 10, 12). The wall is extremely thickened, 2·5 times or even 3 times normal (Nos. 10, 8, 1). In one case the enlargement of the heart, which was very great, was due almost entirely to dilatation (No. 23). In this case also the right auricle formed about one-third of the heart bulk, but in the majority of cases the right auricle was dilated and hypertrophied in proportion to the changes in the right ventricle. The left ventricle shows hypertrophy and dilatation in some cases (Nos. 6, 7, 13, 14, 15, 17, 23).

This series of cases shows no lesions of any importance in the other organs beyond those due to chronic venous congestion. No case of splenic enlargement is reported.

Clinical Review.

In reviewing the cases an attempt has been made to determine which symptoms give the disease, syphilitic arteritis of the pulmonary artery, a true entity and distinguish it from other affections of the pulmonary artery.

The diagnosis from alterations in the pulmonary artery secondary to some underlying cause in the lungs or heart rests with the presence of the symptoms and signs of the underlying lesion. The syphilitic arteritis following on a prolonged history of chronic bronchitis (Ayerza, Arrillaga, Escudero) in the syphilitic subject may produce a terminal clinical picture not unlike the cases under discussion. The history and signs of severe bronchial damage must be taken into consideration. In distinguishing between syphilitic arteritis and non-syphilitic primary sclerosis there is no sure method; only the age and history of the patient will be of assistance.

Symptoms.

Two symptoms take on a significance of the first importance; they are of insidious development and follow a progressive course during the clinical history. These are dyspnœa and cyanosis.

Dyspnœa makes its earliest appearance as dyspnœa on exertion. This may be the only symptom for as long a period as four years (Nos. 6, 7, 11). Nocturnal paroxysmal attacks are frequent (Nos. 6, 7, 14, 21, 23). Later dyspnœa becomes constant with attacks of orthopnœa.

Cyanosis is one of the most characteristic signs but it may be early or late in its appearance and varies greatly in its intensity. Eight cases showed intense cyanosis. Where radiological reports are given it is found that intense cyanosis is associated with increase in the hilar shadows and enlargement of the middle left arc of the cardiac shadow, confirming the views expressed by Thomas that cyanosis in these cases does not appear without general dilatation of the main pulmonary vessels. In some cases (No. 23) cyanosis may be constant, while during attacks of dyspnœa and thoracic discomfort the cyanosis deepens to "black."

Other Symptoms.—A sense of oppression in the thorax (Nos. 1, 8, 23) is sometimes present, often coming on after exertion or during attacks of dyspnœa and increased cyanosis (No. 23). None of these cases has complained of severe pain, such as is described as "angor cœruleus," "angine pulmonaire hypercyanotique," &c. (Vaquez). *Hæmoptysis* may be due to purely vascular change or due to thrombosis with infarction. Hæmoptysis was slight in four cases and profuse in two cases. One case (No. 13) had slight hæmoptysis for three years and then had a sudden attack of hæmoptysis with cyanosis two months before death. This later hæmoptysis was due to thrombus formation in the middle branch of the right pulmonary artery with infarction of nearly the whole of the middle lobe of the lung. On the other hand quite extensive thrombosis or infarction may take place without hæmoptysis (No. 11). *Palpitations* occur during the course but are not constant. *Attacks of vertigo* may be the earliest symptom (No. 1, 2) or may occur later (No. 6). *Somnolence* has been described as a constant and characteristic symptom by various writers but in the present series only two (Nos. 21, 23) cases are reported as showing this symptom. *Clubbing of the fingers* is not described in these cases. It appears to be present in nearly all cases where alterations in the pulmonary artery are secondary to lung or bronchial conditions.

Physical Signs.

The clinical examination of these cases allows the exclusion of more usual causes of cyanosis and dyspnœa by ruling out chronic pulmonary conditions, congenital lesions, or acquired valvular disease of the heart, &c. The total absence of physical signs is one of the most characteristic peculiarities of primary arteritis or sclerosis of the pulmonary artery.

Cardiac.—The pulse is regular. The heart is enlarged both to right and left. The only alteration in the cardiac sounds which appears to be constant is that of reduplication or accentuation of the pulmonary second sound—occasionally a diastolic murmur of pulmonary insufficiency symptomatic of dilatation of the pulmonary artery (Thomas, No. 16). Later, signs of right heart failure or of total cardiac failure appear. Thomas describes a gallop rhythm in many of his cases (Nos. 12, 14, 15, 16, 17, 18) and in some refers it to the right ventricle (Nos. 14, 15).

Pulmonary.—There are no constant physical signs in the lungs. Signs of emphysema or various râles may be present.

Œdema is present in all cases and varies in intensity, some cases showing œdema of the hands, feet, and legs, some showing generalised anasarca (No. 24) or ascites (Nos. 2, 6, 12) in addition. The spleen is not enlarged in the majority of cases (exception No. 23).

Special Examinations.

The Blood.—There are eight records of the number of red blood corpuscles. The counts vary from 5,200,000 to 8,700,000, the average being 6,605,000. There are only six records of the leucocyte count giving an average of 11,160. The counts in individual cases may vary from time to time. In two cases two results are given (No. 15), 5,500,000–7,000,000 and (No. 23) 7,200,000–8,700,000.

The *electrocardiogram* gives valuable information about the state of the right ventricle. There are reports in three cases which correspond fairly closely. Right ventricular preponderance. Rate increased. No arrhythmia in two cases, occasional extrasystoles in one. Inversion of T_2 and T_3 and P_2 large, suggesting auricular hypertrophy.

Radiography.—There are radiographic reports in ten cases. Examination by X rays gives the most characteristic findings and the radiographic appearances are fully discussed by Thomas in his thesis. He points out that the characteristic findings are:

(1) Increase in length and projection of the left middle arc (Nos. 1, 12, 18, 21). (2) Increase in size of the arterial shadows at the hilum with pulsation greater in amplitude and more visible than normally (No. 21). (3) The branches of the pulmonary arteries show more clearly than normal

and can be followed in their course towards the periphery of lung. Some cases show pulsation (No. 14).

These three points he refers to the increased arterial tension.

(4) Modifications of the cardiac shadow due to the enlarged right ventricle with enlargement of the infundibulum of the pulmonary artery and rotation of the heart, causing bulging of the middle arc. (5) When pulmonary insufficiency is present "La danse hilaire" can be seen. The hilar shadows are seen to move with expansile impulses with each beat of the heart. The aneurysm of the pulmonary artery in No. 12 was diagnosed from the radiological examination.

Skiagrams also show the presence of fibrosis whether spreading from the hilum or in the substance of the lung (Nos. 11, 21), and may show the presence of infarcts.

Conclusions.

A well-defined group of cases exists in which arterial disease is confined or largely confined to the pulmonary circuit. These cases differ from other cases with arterial lesions in the lesser circuit in that there is no antecedent pulmonary, cardiac, or bronchial lesion. Twenty-three fully reported cases have been collected from the literature, and a further case is now described.

It is found that syphilis is by far the most important ætiological factor in older patients. Primary non-inflammatory sclerosis of unknown ætiology is found in younger patients. In the syphilitic cases the lesions in the intrapulmonary arteries take the form of an obliterative arteritis, usually most severe in the smaller branches and arterioles. This condition leads to a raised blood pressure in the lesser circuit. Dilatation and hypertrophy of the main pulmonary artery follows with atheroma of the right and left pulmonary arteries and larger branches, whether the latter show inflammatory lesions or not. The right side of the heart becomes greatly dilated and hypertrophied. Clinically the cases are characterised by dyspnœa, cyanosis, and hæmoptysis, and in the later stages by progressive congestive heart failure with a regular pulse.

Syphilitic arteritis of the pulmonary arteries, while admittedly rare, is worthy of notice, since by early diagnosis antisyphilitic treatment might afford some hope of amelioration of the symptoms.

A BIRMINGHAM POOR-LAW HOSPITAL.—The Birmingham Board of Guardians have adopted a scheme for the enlargement of their Dudley Road Hospital at a cost of £80,000. The pressure upon the institution has become very severe. The in-patients have increased from 8867 in 1924 to 13,232 in the year ended with March last; in the same period out-patients grew from 3701 to 17,003. So great is the pressure that of late non-resident nurses have had to be engaged, an expensive process justified only by the lack of accommodation. The existing nurses' home holds 103 nurses, 49 live in adjoining buildings, and over 90 are housed in hospital wards. The proposed extension of the home will accommodate 142 nurses, and is so planned as to permit of further enlargement. It is intended in the future to provide a new mortuary, and post-mortem and pathological departments.

SUBCUTANEOUS NODULES IN THE SCALP

IN FATAL CASES OF GLANDULAR ENLARGEMENT WITH MONONUCLEOSIS.

BY F. JOHN POYNTON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; SENIOR PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
ALAN MONCRIEFF, M.D., M.R.C.P. LOND.,
MEDICAL REGISTRAR AND PATHOLOGIST, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE following two cases present such a remarkable likeness to one another, and such unusual signs and symptoms, that they seemed to us worthy of record, the more so because in one of the cases a post-mortem examination was carried out. How to give a title to this contribution which will enable others to recognise the condition we are attempting to describe is in itself a difficulty, and equally difficult for the same reason is a search of the literature for similar cases. Their interest is increased by the great difficulty in diagnosis, and the liability of falling into the mistake of calling such a case one of rheumatism. It is an interesting fact that rheumatic symptoms are not uncommon among the early warnings of such fatal diseases in childhood as the leukæmias and the grave anæmias. Radiographic appearances in these two cases seem to us to throw some light on these symptoms, though this by no means explains the swelling of the wrists in the second case, which were suggestive in their appearance of Still's disease.

Account of Two Cases.

CASE 1.—A boy, aged 3 years and 3 months, was admitted to the Hospital for Sick Children on Oct. 5th, 1928. He was the only child of parents who are first cousins. He was breast fed as a baby, and remained perfectly healthy up to the beginning of 1928, when he twice had bronchitis. In April, 1928, enlarged glands first appeared in the right side of his neck, and two weeks later he developed some fever, with pain and swelling of his joints. These swellings were fleeting in character, and affected the ankles, knees, wrists, and elbows. During this illness the glands became enlarged in both sides of the neck and in both groins, and these glands remained large up to the time of admission. In June, 1928, the pains in the legs recurred, and the boy was admitted to the Metropolitan Hospital, where he remained for two months, when he was removed by his parents.

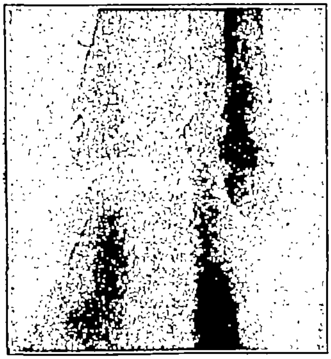
The house physician at the Metropolitan Hospital kindly furnished some particulars of the investigations carried out there. A gland was excised, and the pathological report said: "No evidence of new growth: there is some hyperplasia, but nothing to suggest lymphadenoma." A blood count showed a secondary anæmia with a slight leucocytosis (10,000 per c.mm.), and the differential leucocyte count was normal. The Wassermann reaction was negative.

The boy's condition became worse after discharge from the Metropolitan Hospital, and he was sent to the Hospital for Sick Children.

On admission he was a pale boy, with a somewhat puffy face, of average development for his age. There were masses of enlarged, discrete glands on each side of the neck and on the posterior aspect beneath the occiput. The axillary, inguinal, and epitrochlear glands were also considerably enlarged, and over the mass of glands on the right side of the neck—the largest collection—were many dilated venules. Scattered over the skull were several small hard masses, about the size of a pea, not fixed to the bone, and apparently in the scalp. There were similar swellings, rather more fixed, deep to each eyebrow. The heart was not enlarged, there were no murmurs to be heard, but the first sound was very short and accentuated. The pulse was rapid, 140 per minute, soft, and of poor volume. The temperature was normal. The abdomen was slightly distended, the liver being enlarged about two fingers-breadth below the costal margin, while the spleen was not palpable. There were no signs of disease in the respiratory or central nervous system, and the urine was normal.

Progress.—The pulse remained very rapid, and the swellings on the head became more enlarged. The temperature was now raised, and had a swinging character. Pain occurred in the regions of the left elbow-joint and the right knee.

Radiographic examination showed evidence of rarefaction in the regions where pain was experienced (see figure), and the appearances suggested infiltration of new growth. The parotid glands became enlarged, and on Oct. 20th the spleen became palpable for the first time. The boy's condition became worse, the temperature being more raised, often as high as 102° to 103° F., the pulse was more rapid, 160 to 180 per minute, and the glands became more enlarged, especially in the parotid region. There were no hæmorrhages to be found anywhere over the body nor in the retinæ. He was removed by his parents on Nov. 3rd, and died at home two weeks later with great abdominal distension.



Radiogram showing rarefied areas at end of long bones.

The blood counts in this condition were very puzzling, and are summarised in Table I.

TABLE I.

Date in 1918 ..	Oct. 5th.	Oct. 19th.	Oct. 28th.
	Per c.mm.	Per c.mm.	Per c.mm.
Red corpuscles	3,700,000	3,237,500	2,637,000
Hæmoglobin	40 %	25 %	35 %
	Per c.mm.	Per c.mm.	Per c.mm.
White corpuscles	10,000	32,000	62,000
Polymorphs	29 % (2,900)	8 % (2,560)	6 % (3,720)
Small lymphocytes ..	52 % (5,200)	32 % (10,240)	3 % (1,860)
Large lymphocytes ..	12 % (1,200)	60 % (19,200)	83 % (42,460)
Mononuclears	2 % (200)	—	
Eosinophils..	1 % (100)	—	—
Transitionals	4 % (400)	—	3 % (1,860)

In the last cell count there was also about 5 per cent. of myelocytes, but the predominating cell was a large mononuclear with non-granular cytoplasm, which did not show any granules with the "oxidase" stain. This was called a lymphocyte in earlier films, but was possibly a "pro-myelocyte."

CASE 2.—A boy, aged 2 years and 1 month, was admitted to the Hospital for Sick Children on March 27th, 1920. He was the only child of healthy parents, and was quite well until January, 1920, when he is stated to have had "ulcerated tonsils," and he was ill for three weeks. About a fortnight after this he was suddenly seized with pains in his joints. These pains were somewhat fleeting in character, and affected his hips, knees, wrists, ankles, and especially the finger-joints on the left hand. He improved for a week, and then relapsed, and a fortnight after the beginning of his arthritic pains the glands in his neck became swollen. Feverishness was stated to have been present throughout the illness.

On admission he was a well-nourished, pale child, very fretful, and apparently in pain. The glands on both sides of the neck were obviously enlarged, discrete, and rather tender, while the glands in the axilla and groin were easily palpable. There was some indefinite swelling of the wrists, the left being slightly tender. Radiographic examination of the long bones showed in positions corresponding to the situations of his pain somewhat irregular rarefied areas in the shafts close to the epiphyses. The tonsils were enlarged and red, but without an exudate. The heart was not enlarged, but there was a systolic murmur at the apex with abrupt heart sounds. Over the head were several hard swellings about the size of a pea, not attached to bone, and movable with the scalp. The liver was enlarged to about two fingers-breadth below the costal margin, the spleen was not palpable, and there were no enlarged glands palpable in the abdomen. The respiratory and nervous system were normal, and the urine contained no abnormality. The temperature was raised on admission (100° F.), and the pulse-rate was 140 per minute, the pulse being soft and easily compressible.

Progress.—At first there was some improvement, and the glands became a little smaller. The nodules on the head varied from time to time, occasionally almost disappearing. A right-sided ear discharge developed, and early in May, 1920, the glands in the neck all became larger, while glands over both parotids also enlarged. Some œdema, redness, and tenderness over the right side of the lower jaw developed in association with a septic tooth socket, and shortly after this on May 18th the spleen became palpable. From this time onwards the progress was downhill. The temperature became higher (102°–103° F.) and swinging, a brassy cough developed, and a purpuric rash appeared over the right side of the trunk and legs. The swellings on the head became at first rather larger, but towards the end almost completely disappeared. The heart developed a "bruit de galop," and death occurred on June 14th. The Wassermann reaction was negative.

The blood counts throughout the illness also were somewhat puzzling, and were complicated by the various septic processes which occurred (otitis media, septic tooth). The counts are summarised in Table II.

TABLE II.

Date in 1920 ..	March 28th.	April 16th.	May 3rd.	June 13th.
	Per c.mm.	Per c.mm.	Per c.mm.	Per c.mm.
Red corpuscles ..	4,950,000	2,900,000	3,375,000	806,000
Hæmoglobin ..	60 %	50 %	50 %	Less than 20 %
	Per c.mm.	Per c.mm.	Per c.mm.	Per c.mm.
White corpuscles ..	24,000	11,400	19,000	1,760
Polymorphs ..	50 % (12,000)	28 % (3,192)	54 % (10,260)	—
Small lymphocytes	6 % (1,440)	—	8 % (1,520)	—
Large lymphocytes	28 % (6,580)	46 % (5,244)	24 % (4,560)	—
Mononuclears ..	14 % (3,290)	24 % (2,736)	13 % (2,470)	—
Transitionals ..	2 % (480)	2 % (228)	1 % (190)	—

The large lymphocytes and mononuclears were very similar to the abnormal cells present in Case 1, being non-granular single nucleated cells, giving a negative "oxidase" reaction.

Post-mortem examination was performed 12 hours after death by Dr. C. Kellett.

The scalp showed only a few indefinite areas of thickening; no definite nodules could be found. The skull, brain, and meninges were normal. The thymus was small, the thyroid normal, but all the glands in the neck were distinctly enlarged, as also the lymphoid tissue in the nasopharynx. The glands on section were white and hard, and showed no caseation. The lungs and pleuræ were normal, and there was no enlargement of the mediastinal glands. The heart was slightly enlarged with pale and easily friable muscle. In the abdominal cavity there were numerous enlarged lymphatic glands, especially in the pre-aortic region in the neighbourhood of the pancreas. The liver was pale, somewhat enlarged and firm, and the spleen was moderately enlarged, weighing 60 g., and showed some hyperplasia of the lymphoid areas. There were no naked-eye deposits of any abnormal material in either liver or spleen. The kidneys were pale, and suprarenals somewhat shrunken. The intestines showed hyperplasia of the lymphoid elements, both in small and large bowel. The left femur showed very pale bone-marrow throughout, but there were no definite infiltrations of bone found in the portions examined.

Histological examination showed some evidence of bronchopneumonia in the lungs, and cloudy swelling with fatty degeneration in the kidneys. The liver showed fatty degeneration of the liver cells, and the portal tracts were infiltrated in an irregular manner with small round mononuclear cells with poorly stained cytoplasm. The spleen and lymphatic glands showed definite changes which were similar in both series of sections. These consisted of (*a*) definite increase in the fibrous tissue elements; (*b*) hyperplasia of all the cells with a slight predominance of the endothelial cells; (*c*) slight increase in eosinophils; and (*d*) no evidence of any tubercle formation or of abnormal malignant cells. Some of the endothelial cells were larger than normal, but no definite multinucleated cells were found. On the whole the sections seemed to conform to the "lymphadenoma" type of glandular hyperplasia.

Discussion.

The early age is a remarkable feature of these cases, and this, combined with the pains in the joints and limbs at an age too old for scurvy and, in general terms, too young for rheumatism, is at once perplexing and warns the clinician of difficulties ahead. The deposits in the scalp in these two cases appeared to us very remarkable. They were especially numerous on the vault of the cranium and not in the occipital region; but except for this they were suggestive of unusually large and numerous rheumatic nodules, such as may occur in occasional examples of virulent rheumatism. Further, they varied in size, diminishing in the second case so obviously that everyone was struck by such an occurrence when the disease itself was clearly advancing. There were no nodules on the elbows and knees or elsewhere, except in the first case those lying below either eyebrow. The rheumatic pains in the joints and muscles were striking and in the second case puffy swellings around the wrist-joints were observed in the hospital. In the first case the arthritic symptoms had disappeared before he came under our care, but the history was sufficiently definite to have made the diagnosis of acute rheumatism a probable one to the earlier observers. The blood picture in the first case gradually developed along the lines of an acute leukæmia, and when this child was taken from the hospital the pigeon-hole into which the case was placed was that of leukæmia. In the second case the nearest pigeon-hole appeared to be lymphadenoma.

These two cases appear to us to illustrate a view which we believe to be a valuable one in the study of the blood diseases in young children, which is to throw over boldly any classification based upon classical leukæmia and lymphadenoma, and start anew on the assumption that we are dealing with infective processes to which there is a reaction by the tissues, and by the blood, in particular, of an unusual kind. We recognise that in suppurative infections, such, for example, as empyema, the usual reaction is an increase in the polymorphonuclear leucocytes, that in glandular fever there is a mononucleosis, that in mumps there is a lymphocytosis, and in typhoid fever a leucopenia. It seems a reasonable hypothesis to suppose that the leukæmic and aplastic conditions met with in childhood may represent some disordered response to infection or some curious type of infection which calls forth these unusual results. In both these cases, and in many of the cases of leukæmia in childhood, we find suspicious evidence of previous infection such, for example, as tonsillitis or bronchitis.

It has already been stated that in attempting to search the literature for other similar cases we have been hampered by the problem of under what heading to look. There was a case, however, under the care of Dr. Hugh Thursfield some years ago, and shown at the Section for the Study of Disease in Children of the Royal Society of Medicine in 1925,[1] which was in the memory of one of us as being very similar to the two cases under discussion.

Dr. Thursfield's case was a boy of 4¼ years, who had enjoyed good health until five months before admission to hospital, when the glands in the neck and axillæ enlarged. He had curious nodular swellings in the scalp which, according to the mother, "came and went," and certainly varied in size while he was under observation. His blood count showed a secondary anæmia, while the white cells numbered 7800 per c.mm., of which 90·6 per cent. were lymphocytic. He had severe epistaxis on several occasions, developed a purpuric rash, and had retinal hæmorrhages. His right ear began to discharge freely while he was in hospital, and a septic condition of his lower jaw developed. His spleen was only just palpable, and after making an apparent recovery he became worse again, and died with great enlargement of the spleen. At a post-mortem examination large, pale lymphatic glands were found all over the body, and on section the liver showed a patchy infiltration, with small lymphocytes along the portal tracts, while the spleen was greatly congested and infiltrated with similar small round cells.

This case was presented by Dr. Thursfield as either an unusual type of lymphocytic leukæmia or an abnormal lymphocytic response to some infection, and one subsequent speaker suggested the term "leukæmic lymphadenosis." Whatever label be applied, the case shows remarkable similarity to our two cases: glandular enlargement, sepsis of ear and jaw, nodules in the scalp, a mononuclear type of response in the blood without leucocytosis, and a fatal termination.

The hypothesis we put forward, which this third case would seem to support, may not be sound, but it would lead to a study of the reactions of the blood to infections in childhood unhampered by the conception of certain primary blood diseases. It is well known that the present pigeon-holes set aside do not serve to find a place for many of the unusual blood pictures we find among the anæmias and leukæmias of childhood, and these unusual blood pictures may eventually be found to mark stages in a faulty reaction to infective processes, the final picture being in some cases the classical anæmias and leukæmias which we all recognise.

Summary.

In conclusion, we should like to summarise the salient features of the cases we have described, so that other observers may be able to recognise the condition—subacute onset, glandular enlargement, arthritic pains and swellings, nodules in the scalp, fever, mononuclear response in the blood, slight enlargement of the spleen, serious course and severe nature of the malady, with terminal hæmorrhages in various situations.

TUMOUR IMMUNITY.

TREATMENT BY AUTO-VACCINATION OF IMPLANTED MOUSE CARCINOMA (M. 63.)

BY THOMAS LUMSDEN, M.D. ABERD.

(From the Department of Experimental Pathology, Lister Institute, London, S.W.)

SOME 18 months ago it was shown in THE LANCET[1] that sarcomata (Jensen's) growing in the flank of rats could be caused to regress by injecting 1 per cent. formalin into them, and that the rats so treated were thereafter immune to reinoculation with this tumour in all parts of their bodies. This procedure was named vaccine treatment, because it was held that at some stage of the destruction of tumour cells by formaldehyde, a soluble antigen was produced and absorbed into the circulation in sufficient quantity to arouse immunity.

The justness of this view was evident to those who observed systematically the animals while under treatment, but was less apparent to cancer research workers who had no actual experience of the treatment. This was not unnatural, since Jensen's rat sarcoma is a tumour which induces some concomitant immunity, and hence even rats from which it has been simply excised exhibit thereafter a considerable though lesser degree of resistance to reinoculation.

In order to demonstrate unexceptionably the mechanism involved, it was necessary to show that comparable results could be obtained in the case of a tumour which, it was universally admitted, did not evoke effective concomitant immunity and which could therefore always be successfully reinoculated into an animal from which it had been excised. Such a tumour is the mouse mammary carcinoma, M. 63 of the Imperial Cancer Research Laboratory. Russell[1] stated that this is "a strain giving progressively growing tumours in practically every animal inoculated," and that "its power of inducing resistance is nil." With these dicta all other investigators have agreed. The results obtained by vaccine treatment of this tumour are detailed below.

---

[1] THE LANCET, 1927, ii., 1283.

Experiments.

A single fragment of very active tumour material (M. 63), weighing from 0·005 to 0·01 g., is inoculated into the right flank of each of a series of mice. The mice are examined after a week, and those (generally about 60 per cent.) in which a progressively growing tumour has resulted are separated for treatment. This is begun usually on the eighth to tenth day after inoculation, when the tumour has attained a diameter of 4 to 5 mm—i.e., a size comparable (allowing for the difference in body-weight) to a tumour the size of an orange in man. By means of a very fine hypodermic needle a solution of formalin (1 per cent. in *normal saline*, not distilled water) is injected slowly into the centre of the tumour so as to distend it as much as possible without bursting its capsule, some of the solution is then injected around and deep to the tumour. About 0·1 to 0·25 c.cm. of the formalin solution is inoculated altogether. This procedure is repeated daily until the tumour is evidently disappearing. The decision as to whether treatment should be continued or stopped and the appropriate dose for injection is always difficult and only experience makes the best results attainable. The thing to aim at is gradual regression of the tumour, without so much damage to the surrounding normal tissues and the skin over it as to cause ulceration. In an animal so small and fragile as a mouse this entails delicate and sensitive handling.

T_1, T_2, T_3 represent the number of tumours which had to be treated before immunity (I) or failure (F) resulted. I_5, I_4, I_3, &c.—Immunity evidenced by 5, 4, or 3 consecutive negative tests. The letters W = white, B = black, Br = brown, G = grey, F = fawn, BW = black and white, &c., indicate the colour of each mouse.

As soon as the tumour has regressed and any inflammatory reaction which was present has disappeared, a second—i.e., first test—inoculation of active tumour material is made into the left flank of each treated mouse, controls being inoculated with similar material and dose in *every* instance. In a proportion (about half) of the treated and tested mice no tumour appears, but even so the mice are not judged to be certainly immune until they have been tested three or four times with inocula of increasing amount (0·02 to 0·05 gr.).

If the first test inoculation on the left side gives rise to a tumour it frequently indicates that the tumour originally treated had not, in reality, been eradicated and recurrence on the right side is apt to take place if the test inoculation on the left side is made too early. When this happens both the left flank tumour and the recurrence on the right side are treated with formalin, and only after both have entirely disappeared is the mouse retested.

In a few mice it has been necessary to treat more than two tumours in this way. The detailed results are as shown in the table.

It will be seen that the experiment concerned 55 tumour-bearing mice. Of these 30 were ultimately cured, while in 25 mice treatment failed, and these 25 mice, though the course of the disease was much delayed, ultimately died from cancer. Of the 30 cured mice, 26 were tested for immunity; of these, 15 were found to be immune after treatment of one tumour only, 8 after treatment of two tumours, and 3 after treatment of three tumours. The remaining four cured mice died of intercurrent diseases (such as diarrhœa and pneumonia) before the result of the test inoculation was evident. Of the 26 cured and immune mice:

2 were tested negatively on 5 consecutive occasions.
7 ,, ,, ,, 4 ,, ,,
5 ,, ,, ,, 3 ,, ,,
8 ,, ,, ,, 2 ,, ,,
4 ,, ,, ,, once.

The average number of consecutive negative tests in the 26 immune mice was thus 2·8 per mouse.

While these results are inferior to those obtainable when treating rat tumours[2] they are considered sufficiently striking to demonstrate that the conclusions arrived at previously were sound. Although others have, in rare instances, observed spontaneous regression in the case of tumours of the strain here dealt with (M.63), it is clear from the sentence quoted above that this was not Russell's experience, and in my laboratory spontaneous regression has never been noticed in a series of over 7000 implantations. To have caused regression followed by immunity in 50 per cent. of the treated animals is therefore a significant result, especially since mice are so small and fragile as to make successful treatment of this sort difficult for purely mechanical reasons.

Remarks.

It will be appreciated that in this experiment all the mice were proved to be *not naturally immune*, since they were chosen for treatment only after a progressively growing tumour had resulted from implantation of a fragment of M.63. Any confusion from this source is thus entirely excluded. The virulence of the test material was in *every* instance demonstrated by inoculating it into an equal number of normal mice. In these controls the implantations grew progressively in 80 per cent. to 100 per cent. of the different batches of normal animals. The degree of immunity evoked and the percentage of cures obtained depends on the skill and judgment exhibited by the experimenter, yet it is believed that even an investigator with but little experience of the method will obtain results good enough to convince himself as to the principles concerned, which is, after all, the most important point.

---

[1] Fifth Sci. Rep. Imp. Canc. Res. Fund, 1912, p. 5.

[2] The Lancet, 1927, ii., 1283.

It may be well to recapitulate here some of the details of technique which should be meticulously followed:

1. The original inoculations should consist of a single fragment of very active material about 0·01 g. in weight, and the injecting needle or cannula should be inserted as far as possible from the inguinal glands, since if these get infected cure is more difficult to effect.

2. After sucking the fragment into the injecting cannula the point of the latter should be washed in saline.

3. When treating the tumours inject through a very fine hypodermic needle about 0·1 to 0·25 c.cm. of 1 per cent. formalin in saline very slowly into the growth, trying to distend it without bursting its capsule. Some of the formalin should, before withdrawing the needle, be injected around the tumour.

4. Begin treatment when the tumour has a diameter of 0·4 to 0·6 cm. and continue the injections daily, as long as any definite circumscribed growth can be felt, through the œdematous swelling caused by the injections.

5. Do not test for immunity until it seems certain that the treated tumour has completely disappeared, otherwise the test inoculation is apt to grow and the original tumour to recur. If this happens, repeat the treatment.

6. Keep a careful record of the dates on which each individual mouse has received a formalin injection, and the dates of each test and retest inoculation.

7. Do not inject formalin into the inguinal gland unless it is progressively enlarging or the skin over it looks purplish. It often gets enlarged as the result of simple inflammation and regains its normal size when treatment of the tumour is finished.

A high degree of immunity as indicated by failure of the first and all subsequent test inoculations is most likely to occur when the original tumour was of considerable size—i.e., in the neighbourhood of a quarter to a half gramme in weight—and where its regression has been achieved without ulceration of the skin or much destruction of normal tissue. Since tumours of a variety (M.63) which does not tend to regress naturally are caused to disappear completely, and the animals in which this has been effected are thereafter immune to recurrence or reinoculation, there need be no hesitation in using the word "cure" in relation to the results of auto-vaccination of this sort in the case of the implanted cancers of rats and mice. With the slower growing Twort's carcinoma results equivalent to the above are much more easily attained.[4]

Taken along with the results previously reported the above findings indicate that by means of auto-vaccination we are either (1) aiding by our intervention some natural protective mechanism which every animal possesses, or (2) evoking some new curative process. The former appears to the writer the more probable of these alternatives. A general review of the pertinent observations suggests that all animals exhibit in varying degree resistance against the growth of any variety of tumour cells inoculated into them. If this be so, any sharp classification of tumours into two distinct groups—viz., those which give rise to concomitant immunity and those which do not—is misleading.

The facts that implantations of heterologous tumours never grow progressively, that homologous tumour implantations sometimes fail to grow and sometimes spontaneously regress, and that in rats tretted by auto-vaccinatinn autoplasties of spontaneous tumours are not invariably successful, all lend support to this view. The rare but well-authenticated cases of spontaneous recovery which have been observed in man give justification for the hope that even in the case of human cancer the body resists the invasion of its tissues by malignant cells, by means of a mechanism comparable to that by which it resists the growth of implanted tumours—a mechanism which it may, in like manner, be possible to assist to the extent of rendering it effective in a large proportion of cases.

In the long series of experiments previously reported[5] the aim has been to discover the mechanism of the spontaneous control or cure of cancer, and the conclusions arrived at are that natural recovery is, in the case of implanted tumours, characterised by the production of anti-malignant-cell bodies in the serum of the affected animal, along with the elaboration by extravasated leucocytes of a lytic substance capable of destroying (even homologous) cancer cells.

The facts observed suggest that the agency which induces this process of regression is the absorption from the tumour area of some product of dying tumour cells which provides the necessary antigenic factor. Evidence in favour of this view has been published in previous communications.[6]

In the above schema the facts herein reported are of interest as indicating that the methods which evoke increase of immunity against a tumour which gives rise to a high degree of comcomitant immunity—e.g., J.R.S.—are applicable to a tumour of which it has been agreed that, in the words of Russell, "its power of inducing resistence is nil"—viz., the mouse carcinoma, M.63 of Imperial Cancer Research.

One further step has to be taken in lower animals before human tumours can be hopefully treated along these lines. It is necessary to discover whether vaccine or serum treatment can be effectively applied to spontaneous mouse and rat tumours. The author has now bred some 700 mice from a strain kindly sent him by Dr. Burton T. Simpson, of Buffalo, U.S.A. Seventy per cent. of the *females of this strain* are, in America, found to develop spontaneous mammary cancer when they reach the age of 5–20 months. If a similar proportion of these mice develop tumours in this country (none has done so yet), the great initial difficulty of obtaining an adequate amount of experimental material should be obviated. It seems certain that it will be especially difficult to evoke immunity against spontaneous and therefore autologous tumours, but it may nevertheless be found possible to overcome this final difficulty. In any case the attempt must and will be made as soon as sufficient material is available.

Summary and Conclusions.

1. In 30 out of 55 mice in which mammary cancer (M.63) was growing progressively, the tumours were caused to regress by auto-vaccine treatment (injection of 1 per cent. formalin saline into the growth) and the mice so cured showed a high degree of immunity against subsequent implantations of the tumour.

2. The facts reported indicate that all animals resist the invasion of their tissues by implanted (and possibly by spontaneous) tumour cells, through a mechanism which can be strengthened by auto-vaccination. In the case of certain animals and tumours this natural mechanism is without further stimulation occasionally sufficient to prevent progressive tumour growth—e.g., Jensen's sarcoma in rats. In other instances the unaided natural resistance is inadequate—e.g., M.63 in mice. It is misleading to think of implantable tumours as falling into two discrete groups—viz., one group in which concomitant immunity is evoked and another in which no such immunity appears. No hard-and-fast line can be drawn between the one group and the other. Any differences seen, appear to be not in kind but only in degree.

The author gratefully thanks Sir Charles Martin, F.R.S., for helpful criticism and for facilities at the Lister Institute, the British Empire Cancer Campaign for its grant, and Miss A. C. Kohn Speyer, M.A., for assistance in keeping records of the experiments and in other ways.

THE SOUTHEND HOSPITALS.—New mental wards of Rochford Poor-law Hospital have recently been opened. The institution will be taken over by the Southend Town Council when the guardians are disestablished, and cases will then be received from the area outside Southend. The Rochford Board of Guardians have refused to renew their subscription of £125 to the Southend Victoria Hospital unless they are represented on the governing body.

Clinical and Laboratory Notes.

A CASE OF
SEBACEOUS CYST UNDERGOING MALIGNANT CHANGES.

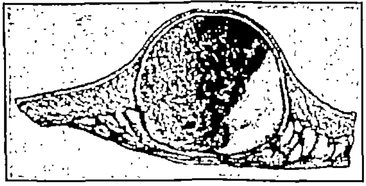
BY A. CLIFFORD MORSON, O.B.E., F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL FOR URINARY DISEASES; SURGEON TO OUT-PATIENTS, HAMPSTEAD GENERAL HOSPITAL;
AND
C. RICKWOOD LANE, B.M. OXF., D.P.H.,
PATHOLOGIST TO HAMPSTEAD GENERAL HOSPITAL.

THE danger of neglecting to act upon medical advice with regard to the treatment of a simple tumour has been well exemplified in a case which recently came under our observation.

Colonel A., aged 75, consulted one of us about four years ago on account of a swelling on the back just below the angle of the right scapula. He had had no pain, and his attention had been drawn to its presence by the attendant at a Turkish bath. On examination the tumour proved to be a simple sebaceous cyst. The patient was told that its removal was an easy matter and entailed very little discomfort, but nothing more was seen of him until December, 1928, when he once more asked for an interview. His story was that he had enjoyed good health since his last visit, and that he was only seeking advice because the Turkish bath attendant had informed him that something seemed to be going wrong with the lump on his back. Investigation revealed the fact that a hæmorrhage had occurred into the cyst which was the size of a walnut, and that there was considerable infiltration of the subcutaneous tissues. There was no evidence of inflammation.

It was represented to the patient that excision of the tumour was now urgently required, and permission was obtained to operate under local anæsthesia. A 1 per cent. solution of novocaine was injected beneath the skin and into the cellular tissue around the cyst, and by an elliptical incision the whole mass down to the muscles of the back was removed. The convalescence calls for no comment.

FIG. 1.



A drawing of the tumour as it appears on vertical section.

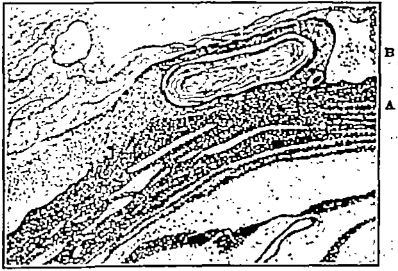
The interest of this case lies in the pathological changes which apparently occurred during the course of the last four years.

Sebaceous cysts commonly become inflamed and suppurate. They may even fungate, producing a foul offensive mass which has been mistaken clinically for a cancer. Rarely an encapsuled tumour somewhat resembling a sebaceous cyst has been observed growing from the scalp. This is filled by a folded ingrowth of squamous epithelium, and has been given the name of "benign epithelioma." The case which we record is clinically a sebaceous cyst, but on histological examination proves to be a basal cell carcinoma. Most of the red mass (which appears dark in Fig. 1) consists of fairly recent blood clot which is beginning to organise. The white mass in the bottom right hand segment consists of structureless homogeneous material.

The capsule is formed of rather cellular fibrous tissue, and externally forms a definite boundary everywhere except at the most prominent part of the tumour where it blends with the skin epithelium. Internally the capsule is less defined and at places shows island of fairly normal squamous epithelium forming horny pearls. Lying beneath the capsule and tending to blend with it is a mass of cells of basal cell type arranged in anastomosing strands to produce a reticular appearance, some of the spaces of which are occupied by a loose connective tissue with very thin-walled blood-vessels, some by only a thin-walled blood sinus, and others by homogeneous acellular material.

At certain places the basal cells can be seen to be originating from one of the islands of squamous epithelium mentioned above; this is well shown in Fig. 2. At other parts these cells are arranged in a manner recalling the structure of a sweat gland. This tissue lines the whole of the internal surface of the capsule, except opposite the white mass of structureless material. It varies in thickness, and in one place forms a band which can be recognised microscopically as a mass somewhat lighter than the blood clot.

FIG. 2.



Microscopic section showing outgrowth of basal cells (A) from an island of squamous epithelium (B).

The presence of the epithelial islands in the position described bears out the clinical finding that the tumour was originally a sebaceous cyst; the origin and type of cells in the new growth are those of a basal cell carcinoma (rodent ulcer). The somewhat unusual arrangement is what might be expected from the fact that the tumour has grown into a non-resisting structureless mass and has had to form its own stroma and blood-vessels. To this fact also the extensive hæmorrhage may be attributed.

AN OUTBREAK OF SCARLET FEVER AMONGST ADULTS.

BY J. TODESCO, M.D. FLORENCE, M.R.C.S. ENG.,
RESIDENT MEDICAL SUPERINTENDENT, BOROUGH HOSPITAL, CROYDON.

DURING the first six months of 1929 322 cases of scarlet fever were admitted to the Borough Hospital, Croydon, and 74 (23 per cent.) of these were in-patients between the ages of 15 and 50 years. In the corresponding period of 1928 there were 259 scarlet fever cases, of which only 34 (13 per cent.) were in this age-group. Most of the scarlet fever admissions in 1929 were in March and May, whereas in 1928 the number was greatest in February, after which there was a steady fall. The greatest incidence of the disease was in the age-group 15 to 20 years, as shown in the table.

Ages.		M.		F.	Ages.		M.		F.
15–20 years	..	12	..	13	40–45 years	..	1	..	1
20–25 „	..	6	..	13	45–50 „	..	—	..	2
25–30 „	..	7	..	4			—		—
30–35 „	..	3	..	4					
35–40 „	..	2	..	0	Total ..	..	31		43

M. = males. F. = females.

Many of the 74 cases were of the septic type with intense rashes, marked injection of fauces, and dirty tonsils, glandular enlargement, and high fever. The complications were as follows: adenitis, 6; albuminuria, 2; rheumatism, 2; rhinorrhœa, 5; otorrhœa, 1; secondary sore-throat, 5. There were two relapses on the 17th and 24th days.

Of the cases of septic type 25 were treated with scarlet fever streptococcal serum, of which they received 10·0 c.cm. intramuscularly on admission—i.e., between second and fourth day of disease. Serum rashes with slight rise of temperature and joint pains, either scarlatiniform, urticarial or papular, were noted in 12 cases, the rash appearing within 7–14 days of injection and usually lasting 24–36 hours, but there were no cases of serum sickness. The giving of serum did not seem to bring down the temperature more rapidly, but no relapses occurred in the serum-treated cases. The average stay in hospital for the serum cases was 30 days, whereas it was 31 days for the others.

The interesting feature of this outbreak is that 23 per cent. of the cases occurred after the third quinquennium of life, whereas the disease is usually commonest between the ages of 2 and 6, two-thirds of the cases occurring, as a rule, in the first and second quinquenniums. According to Kerr, cases are few in number after the age of 15 years. The giving of scarlet fever streptococcal serum did not seem to affect the incidence of complications or the length of stay in hospital to any great extent. All but one of the serum cases which developed complications were females.

I wish to thank Dr. Oscar Holden, medical officer for Croydon, for permission to publish this note.

A CASE OF
BRUCELLA ABORTUS INFECTION IN MAN.

By H. E. Bloxsome, M.R.C.S. Eng.,
SURGEON TO THE FAIRFORD COTTAGE HOSPITAL.

With a Pathological Report by
E. N. Davey, M.D. N.U.I.,
PATHOLOGIST TO GLOUCESTER ROYAL INFIRMARY.

A DISPENSING chemist, aged 50, was attacked at the end of last March by what I called influenza.

The onset was sudden, with chilliness and sweating, and some headache and fleeting pains. The temperature was moderate, and I thought he would be well in a week; but at the end of that time his temperature was still 101° F. at night, and his pulse-rate kept steadily high (120). He sweated a great deal, but had no aches or pains, and on examination I could find no physical signs. There was no previous medical history of note, except occasional febrile attacks in winter.

The patient was thin, and had a slight cough, so I asked Dr. W. A. Dickson, the Gloucestershire tuberculosis consultant, to see him, but he could not find any physical signs in the chest, abdomen, or central nervous system. The urine was free from albumin and sugar. The bowels acted normally. The features of the illness were the drenching sweats and the undulant character of the fever, and the rapid and weak pulse. He had no joint pains, and no enlargement of spleen or liver. After about a fortnight of this pyrexia I sent a specimen of his blood to Dr. Davey, who reported no signs of typhoid or the paratyphoids. He found, however, that the serum agglutinated the *Brucella abortus*—a strain of which he was working with at the time. The patient lived a very sedentary life, and seldom went out except on his motor-cycle, so that he had not come into contact with any animals; he drank very little milk, and had only once been out of his market town in a year, for half a day. No one else in the town had shown any signs of a mysterious disease. His brother had rather a prolonged influenza, which we afterwards thought might have been this infection, but his blood did not clump the bacilli.

The drug treatment used was urotropine grs. x t.d.s. Quinine in 5-grain doses had no effect on the temperature. After a course of urotropine the patient himself suggested salol, and from the moment it was employed the fever abated—post hoc probably, but worth remembering in a future case. The febrile period was about three months, and the temperature was normal by June 25th. On August 21st, however, the patient had to be readmitted to the Fairford Cottage Hospital with a recrudescence of a milder type. On this occasion his pyrexia lasted only ten days. He has now (Oct. 12th) resumed work.

There is always a great deal of contagious abortion in this neighbourhood, the veterinary surgeons tell me; but there is no clue to show how this patient picked up the organism.

Pathological Report by Dr. Davey.

Owing to the prevalence of contagious abortion amongst cattle in this area, we have been making it a practice to examine all sera submitted for agglutination reaction for typhoid fever, against the *Br. abortus* Bang, Oxford standard cultures.

The serum of this patient was submitted on May 7th. It gave a negative reaction with *B. typhosus* and *B. paratyphosus* A and B, but was found to agglutinate *Br. abortus* in dilutions of 1 : 25 to 1 : 250. When the agglutination was carried to its highest titre it agglutinated in as high a dilution as 1 in 5000 after four and a half hours' incubation. It also agglutinated *Br. melitensis* in dilutions of 1 : 25 to 1 : 500.

We saw the case in consultation on May 13th, and beyond the tachycardia and high temperature there were no objective signs present. The blood count was: red cells, 3,000,000 per c.mm.; white cells, 5600 per c.mm. Differential white cell count: polymorphonuclears, 42 per cent.; small lymphocytes, 45 per cent.; hyalines, 8 per cent.; and myelocytes, 5 per cent. Blood cultures in Douglas's broth and trypsin broth and on serum and blood-agar were sterile after six days' incubation; both aerobically and under partial CO_2 pressure. Urine cultures were sterile.

On July 12th, after the temperature had subsided, a further agglutination reaction was performed, the titre then being *Br. abortus* 1 : 25 to 1 : 2500, and *Br. melitensis* 1 : 25 to 1 : 500. The patient was again seen on August 19th, when he was convalescent. His only symptom was tachycardia, and his blood picture was: red cells, 4,500,000 per c.mm.; white cells, 4600 per c.mm.; hæmoglobin, 60 per cent.; colour-index, 0·66. Differential count: polymorphonuclears, 47 per cent.; small lymphocytes, 30 per cent.; hyalines, 18 per cent.; myelocytes, 5 per cent.

The interesting points in connexion with this case are: (1) The very high agglutination titre, the fact that it was higher for *Br. abortus* than *Br. melitensis* being diagnostic of an infection with the former organism. (2) The leucopenia with relative lymphocytosis, which persisted well into convalescence. (3) The absence of any signs beyond the undulant character of the temperature which would lead to a diagnosis of the condition other than by the presence of agglutinins in the patient's serum. It is becoming increasingly important in this country to examine sera in cases of pyrexia of unknown origin for *Br. abortus* agglutinins.

Donations and Bequests.—Mr. Henry Dakin, of Millers Dale, Buxton, left one-third of his estate amounting to over £4000 upon trust for his brother for life with remainder to the Derbyshire Royal Infirmary, part of this bequest to be used to endow a Henry Dakin bed.—Miss Ellen Constance McKee, of Bentinck Mansions, Bentinck-street, Marylebone, left £500 each to the Elizabeth Garrett Anderson Hospital, Euston-road, and the South London Hospital for Women, Clapham Common; £250 to the London (Royal Free Hospital) School of Medicine for Women; and £100 each to the National Education Association, Caxton House, and the Association for Moral and Social Hygiene, Great Smith-street, Westminster.—Miss Evelyn Winifred Riley, of Harrington-gardens, South Kensington, left estate of the value of £178,189, and made many bequests to charities, including £1000 each to the Royal Surgical Aid Society, the United Kingdom Beneficent Association, and the National Society for the Prevention of Cruelty to Children; £500 each to the West London Hospital, the Hospital for Women, Soho-square, the Middlesex Hospital, and the National Institute for the Blind, Great Portland-street; and £100 to the Society for the Prevention of Cruelty to Animals. She left £14,500 in trust to pay certain annuities and subject to such annuities between the Surgical Aid Society, the United Kingdom Beneficent Association, the Society for the Prevention of Cruelty to Children, the West London Hospital, the Hospital for Women, the Middlesex Hospital, and the National Institute for the Blind.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PATHOLOGY.

ON Oct. 15th Prof. A. E. BOYCOTT, F.R.S., delivered a presidential address to this Section on

THE BLOOD AS A TISSUE.

Besides being a carrier of food, excreta, and hormones, the blood, he said, is a tissue. As such it has a life of its own, malformations (e.g., acholuric jaundice) and tumours (e.g., leukæmia, splenomegalic polycythæmia), and can be studied for itself. There being no name for the total quantity of red corpuscles with the marrow cells from which they come, he suggested the word "erythron" as convenient. Hypertrophy of the erythron is caused by relative lack of oxygen whether this is due to high altitudes (anoxic type of Barcroft) or slowness of circulation (stagnant type), though in many cases of heart disease the associated increase in viscosity would be harmful and the reaction does not occur. Similar active growth (regeneration) in anæmia is also due to anoxæmia (anæmic type). Atrophy of the erythron is caused by relative excess of oxygen as in compressed air, persons returning from high altitudes to sea-level, and after transfusion. Hypertrophy and atrophy are both conditioned by the needs of the animal; similar conditioned responses (atrophy and regeneration) in the liver and kidney in mammals, in the claws of a prawn, and in the tentacles of a worm were considered. In all cases the result has the appearance of a purposive action, and it was urged that a frank acceptance of a teleological outlook made pathology more intelligible and formed a sound guide in investigation. The normal quantity of hæmoglobin and its concentration in the blood is a compromise between the desirability of having plenty of oxygen and the disadvantage of having blood which is too viscous, the best balance depending on the rate of the circulation.

SECTION OF NEUROLOGY.

AT a meeting of this Section held on Oct. 10th, the retiring President, Mr. DONALD ARMOUR, introduced Dr. GORDON HOLMES, who delivered his presidential address on

DISSOCIATION OF THE OCULAR MOVEMENTS.

It was often assumed, he said, that the almost ceaseless movements of the eyes were purely voluntary; indeed, clinical pathology and physiology had shown that the majority occurred without the intervention of the cells in the higher regions of the cortex. These movements were, however, profoundly influenced by labyrinthine activity, other sensory impressions, proprioceptive stimuli from the muscles of the neck, and probably also by the basal ganglia. A very large number of ocular palsies were theoretically possible. Dr. Gordon Holmes said that some of these had been recognised and these would form the subject of his address, together with observations on five patients who had been under his care.

The essential feature of a lesion of the pons in the neighbourhood of the sixth nerve nucleus was the loss of conjugate movements towards the paralysed side; these could not be obtained voluntarily, reflexly, or by any other means. The result was like that of an interruption of the final common path, but that the internal rectus contracted normally on convergence. The paralysis was therefore not of muscles but of movement. The possibility of loss of associated movements of the eyes, in spite of the integrity of muscles, nerves, and nuclei, had been described in 1883, and the first example had been recorded in 1895 (Oppenheim's case). Many cases manifesting very varied clinical signs had been recorded since then.

A typical case had first been seen by Dr. Gordon Holmes three months after the acute onset of the trouble. At that time the vertical and convergent movements were quite normal, but there was absolutely no deviation to the right. The eyes moved very slightly to the left of the midline, but the movement was incomplete, jerky, irregular, and required a great effort; it showed what Hughlings Jackson had called "punctuation of movement." The patient could, however, follow a moving object if it were not moved too rapidly or jerkily. If he fixed a stationary object and rotated his head his eyes remained fixed on the object; they therefore deviated fully and regularly—i.e., they responded normally to proprioceptive impulses from the neck muscles. When the eyes were fully deviated to the right he could not move them back to the centre; they only returned when the object was brought back or the head was rotated to the left. Later on he learned to bring his eyes back by blinking repeatedly and firmly closing the lids. In the street he relied on head movements, and if any object excited his attention just as he wanted to turn the eye would remain fixed and would not turn with the head, which was often very awkward. Reading was slow and awkward; he had to pick out each letter in succession. The end of each line offered great difficulty; almost the only therapeutic success obtained was in teaching him to fix his eyes on his finger at the end of each line, and move it back to the beginning of the next. Irrigation of the left ear with cold water, which normally causes vertigo and nystagmus with a quick component to the right and a slow one to the left, brought about no change in this patient, even after three minutes, and when 600 c.cm. of water had been used, but his outstretched arms deviated normally to the left. However, as soon as the irrigation ceased his eyes deviated slowly and forcibly to the left, and remained there for two or three minutes. When the right ear was similarly irrigated there was no nystagmus or deviation, but at the end of the process the eyes moved slowly to the right and became fixed, so that for a few seconds he could not even follow a finger or move them by rotating his head. He was remarkably tolerant to galvanic stimulation of the labyrinth; even 12 milliampères caused no vertigo, but it induced some deviation of the eyes to the right. Briefly, therefore, the quick phase of nystagmus was absent in this patient, who was by no means an isolated example. Another patient who had lost voluntary vertical movement showed forcible, almost violent, deviation upwards when rotated clockwise in a chair with the head bent to the right shoulder. With the head on the left shoulder both eyes deviated downwards, but in neither case did the rotation cause the normal nystagmus with a quick component downwards. Other observers had recorded the same phenomenon.

The Quick Phase of Nystagmus.

The highest levels of the central nervous system were probably concerned in the quick phase of nystagmus, which might be located in the cortex. On the other hand, typical labyrinthine nystagmus could be induced in animals from which the whole brain above the mesencephalon had been removed; the cortex might, however, play a more important part in the optic reflexes of the higher animals. There was no evidence in favour of the influence of the cortex on the quick phase of nystagmus, except that cold aural irrigation produced conjugate deviation instead of nystagmus in patients comatose from various causes. This phenomenon had been ascribed to inactivity of the cortex in coma.

The inevitable conclusion seemed to be that the symptoms seen in these patients were due to damage of some mesencephalic structure by a lesion which at the same time interrupted the paths of voluntary movement of the eyes in the immediate neighbourhood of the vestibular apparatus. In some of these palsies stimulation of the labyrinth might make voluntary deviation possible. There had been much discussion of this relative movement, which was generally regarded as a labyrinthine reflex. Certain observations, however, were hard to explain on this hypothesis, and suggested a calcarine-cortical reflex. The weight of evidence, however, was in favour of the labyrinthine origin.

If the head of the first patient were passively rotated in a dark room with his eyes closed, the eyes deviated to the opposite side, but more promptly and forcibly to the right than to the left, while vertical movements could not be provoked. Since retinal impressions were certainly not active, this deviation must have been excited by proprioceptive impulses, either from the labyrinth or from the muscles of the neck, probably the labyrinth. Later on, when he had begun to recover, he was tied in a chair with his head fixed so that no neck movements were possible; his eyes were closed, the room was darkened, and the chair tilted to the right through 90°. No deviation was obtained, but by this time a fair range of voluntary movement to the left had been recovered. If the chair were tilted to the left through the same angle, the eyes deviated strongly to the right and stayed there. The deviation was always more marked if the movement were slow and uniform than if it were quick or irregular. The fact that the semicircular canals were more stimulated by rapid movement suggested that spastic deviation of the eyes in the direction in which movement was lost might be excited by the otoliths.

The Maculo-calcarine Reflex.

The ability to follow a fixed object if moved slowly and steadily had been noticed in most of the recorded cases, but was defective or absent in some. One patient could not bring her eyes above the horizontal; clockwise rotation in a chair with her head on her right shoulder produced no nystagmus or deviation, but opisthotonus and faintness. In some patients the eyes failed to follow an object, but they could usually follow it if it were moved at a uniform slow rate. There must be separate mechanisms involved in these two forms of deviation. No part was played by the labyrinth when the head was fixed; retinal impressions only were active. Some authorities thought the deviation was evoked by a short direct reflex through the superior quadrigeminal body and external geniculate body, but this was disproved by the fact that only objects in the field of attention and fixed by the conscious will could be followed; it was of no use to move some chance object. The reflex was a true cortical one in which the calcarine visual sphere was active. The affective stimulus must come from the region of the maculæ, therefore the reflex was maculo-calcarine. Apparently only impressions from the immediate neighbourhood of the fovea were potent, so that steady movement of the object was essential in order that the eyes might make a series of minute movements, each of which brought an extra-foveal image on to the fovea, in the same way that the first patient climbed from letter to letter in reading. The patient was, in fact, able to deviate his eyes through a very small angle. The path of the maculo-calcarine reflex was conjectural.

In two patients optic nystagmus had been investigated from another point of view. A drum with figures on it had been rotated vertically. Normally this led to nystagmus with its slow phase in the direction of rotation as seen by the patient. In this nystagmus the cortex intervened; it depended on the integrity of a path between the visual area and the frontal lobes. In one patient the drum produced normal nystagmus when rotated on a horizontal axis, but rotated on a vertical axis it caused no nystagmus but extreme deviation of the eyes in the direction towards which the slow phase of nystagmus would have occurred. The eyes remained fixed for several seconds. Another patient had lost voluntary upward movement. When the drum was rotated upwards on a horizontal axis the eyes deviated upwards spasmodically. It was, therefore, possible to evoke spasmodic deviation like that of labyrinthine stimulation by visual stimuli alone. The deviation was always in the direction of the slow phase of the absent nystagmus and persisted for some time, in one case for five minutes; the patient was unable by voluntary effort to return the eyes to the position from which they had been deviated. Neither labyrinthine nor proprioceptive neck mechanisms were concerned in this deviation, which must be caused by retinal or ocular stimuli. No other form of prolonged retinal stimulation had the same effect, so the cause was probably proprioceptive apparatus in the orbits or ocular muscles. There was a release of some subcortical mechanism, probably in the mesencephalon.

Oculogyric Crises.

One patient had complained that her eyes were "not under control." The first patient had given an intelligent description of the same sensation. Six months after the onset of his trouble, when rapid improvement was setting in, he had first experienced double vision, which he attributed to the spasmodic inturning of the right eye, which might remain fixed for a couple of hours. A few months later the left eye began to do the same thing, and might stay fixed for two or three days. Three years later, when some voluntary movement had been regained, the eyes would at times, especially first thing in the morning, turn to one side and stay fixed for a few seconds. The patient said they seemed "too loose" and that they "rolled about, so that he could not get them on the thing he wanted to see." This suggested the oculogyric crises of epidemic encephalitis. There were two types of spasm: spasm of individual muscles and conjugate deviation as in oculogyric crises, and the deviation excited by labyrinthine and retinal stimuli. Compulsive ideas and other mental stimuli appeared in oculogyric crises. The patient in whose eyes a rotating drum caused deviation complained of discomfort and, as deviation increased, of actual pain, until finally he sweated and shrieked that his eyes were being torn out of his head and the test must stop. He used the same word "agony," so often used by sufferers from oculogyric crises.

Although these patients eyes could not be moved voluntarily they often moved involuntarily, as if exploring space around them, when the attention was diverted from the eyes. This often suggested an hysterical origin of the trouble but really indicated lower level mechanisms which had escaped damage. Dr. Gordon Holmes said he had tried to provoke these movements, but had only succeeded in one man who was unable to deviate his eyes to the right. If his head was fixed and a loud and unexpected sound was made to his right, his eyes would sometimes come round for a moment in the direction of the sound. Oppenheim had also obtained this reaction to sound.

No anatomical findings had been published in these dissociated supranuclear ocular palsies. In most cases the trouble was undoubtedly a thrombosis or hæmorrhage. Localisation had been determined in two patients, and in both the site had seemed to be in the mid-brain. In a few of the earlier cases extensive bilateral softening of the forebrain had been found.

A vote of thanks to the President was proposed by Dr. A. S. BARNES and seconded by Prof. EDWIN BRAMWELL.

BIRKENHEAD GENERAL HOSPITAL.—Last week a new out-patients' department of this hospital was opened. The accommodation includes a large waiting-hall, the usual examination rooms, an orthopædic room, eye, ear, nose, throat, and dental departments, an almoner's office, and a buffet for the refreshment of patients from a distance.

"TINFOIL BEDS."—The Province of Mercia of the Ancient Order of Druids last week completed the payment of £1250 for the dedication of a bed in the Birmingham General Hospital. The money has been derived from the sale of tinfoil. The Druids have from this source endowed 20 beds in various hospitals since 1910.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Dr. J. F. Halls Dally delivered the presidential address before this Society on Oct. 4th. The following is an abstract of what he said on

Low Arterial Blood Pressure.

Hypopiesis includes all forms of absolutely low arterial pressure, whether these be physiological or pathological, temporary or permanent. Any pressure which falls below the limit of 110 mm. Hg systolic is said to be absolutely low, since those above 110, which may be relatively low for age, sex, and body-weight, fall into a different category. The diastolic is prone to vary more widely. One person, for example, may have a systolic of 100 and a diastolic of 80, while another may have a similar systolic of 100, but a diastolic of 55. Of the two pressures, the diastolic is of by far the greater importance, since it is a more constant indicator not only of the propulsive force of the heart and of the eliminatory capacity of the body, but also of peripheral resistance and vasomotor nervous tone. Hence, in the absence of disease of the heart muscle or valves, a notable fall in diastolic pressure, such as occurs in conditions of shock, points to peripheral damage to the vessels. A further illustration may be noted during the acute stage of influenza. Often the lowest average diastolic pressures are found in association with autonomic-endocrine disturbances, and the highest in nephritis. In general it may be said that the common range of absolutely low arterial pressures is from 110 to 90 for the systolic pressure, and from 80 to 60 for the diastolic pressure at adult ages in men, and slightly less for women.

Low Pressure as a Symptom.

Low arterial pressure is met with as a symptom of many diverse conditions. Physiologically it is induced temporarily as a result of quiet sleep, recumbent rest, fatigue, moist heat, the menstrual cycle, pregnancy, and labour. It tends to become permanent in athletes, in those of placid and gentle temperament, in routine occupations, uncomplicated old age and warm climates. It follows acute collapse and shock, intoxications and circulatory disorders. It may be congenital and persistent, or acquired and persistent. It accompanies nearly all the acute infections, chronic states attended by wasting, certain constitutional affections, the anæmias, chronic infections and intoxications, and as a terminal event. Thus the list of associated conditions is a long one, and since low arterial pressure has been stated by every previous observer to be compatible with perfect health, it will readily be appreciated that the scanty literature on this subject has reach no definite conclusions about its ætiology.

The only way in which the paradox becomes simple is first to dismiss groupings based solely on clinical or anatomical conditions of association, and next closely to examine hypopiesis in the light of modern conceptions of metabolism.

Any factors that upset metabolic balance cause either nutritional or endocrine disequilibrium, or both. Hormonic dysfunction in combination with vasomotor disturbance leads to variations in arterial pressure, and inability to respond to stimuli in adequate fashion tends to produce symptoms of insufficiency of which low arterial pressure is one of the most important. Thus I have sought a comprehensive and unifying principle that would explain the striking diversity of association of low arterial pressures, and would link them with the incidence under opposite conditions of high arterial pressures. This unifying principle has been arrived at along the lines of biochemical investigation, and by expansion of the well-known dictum of the late Sir James Mackenzie that "response to effort" is the most valuable test of circulatory efficiency. Hence I have stated as "The Biological Law of Hypopiesis" that "low arterial blood pressure is always to be regarded as an expression of a low vitality state." In other words, the hypopietic subject is never a normal individual, but exists in an inferior constitutional state in which he suffers from inadequate and low reactive capacity to normal and abnormal stimuli. Up to a point stimulation is beneficial but, even so, the reactive capacity is diminished as compared with that of subjects in perfect health, and, if stimulation be carried to a point just beyond the narrowed limits of reserve force, depression of vita energies rapidly ensue. The whole matter resolves itself into cellular, lymphatic, capillary, and endocrine balance.

For diagnosis and prognosis it is necessary (1) to differentiate the case capable of reacting to stimuli from that which is incapable, and (2) in the former case to assess the degree of reactive capacity. This may be done by hypodermic injection of 1 c.cm. of 1 in 1000 adrenalin solution. Pressures are recorded at the end of each five minutes for four consecutive readings. Such a series of observations shows that, whilst in some people after injection the pressure levels rise, in others there is little or no change.

Clinically, low pressure subjects tend to poor bodily build; they are thin and pallid, with narrow chests, low diaphragms, and small elongated hearts. Length predominates over breadth. Through errors of assimilation they are deficient in calcium and other vital salts. Hence they are prone to respiratory diseases. At school unstable and unsatisfactory they do little that is worth while. Mental response is slow, although given sufficient time a correct answer may be elicited. In games they are usually ineffective, and though able to sprint 100 yards, they cannot last a 220 yards' race, nor keep up with their fellows in long-distance runs. Lethargic and easily fatigued, the capacity for sustained interest is lacking, and they soon become bored. Notwithstanding a poor youth, as life goes on these subjects tend to improve, and, though during childhood and adolescence frequently requiring medical attention, seldom need a doctor after 50, and often live to a ripe old age. Tardy in development and sluggish in habit, they are static rather than dynamic, taking long in their profession or business to make good, but in later life are often found to have shot far ahead of their high pressure competitors, who in early days carried all before them in work and sports. The last stages of these high pressure people are worse than the first, whereas low pressure subjects, having fought through their initial disabilities, from the standpoint of longevity are welcomed by life assurance companies. Naturally there are exceptions to the rule, hypopiesis being at times encountered in those of sthenic habitus, but, even in these, careful investigation often reveals evidences of narrowed reserve capacity. The basic proposition that hypopiesis is invariably an expression of low vital capacity based on inherent or acquired nutritional defects has proved a stumbling-block to those who cite the performances of certain athletes in support of their contention that low arterial pressure is compatible with well-sustained effort such as long-distance running. If one analyses these cases, however, one finds that the majority do not belong to the class of absolute hypopiesis with systolic pressure below 110 mm. to which my law refers, but are in reality instances of relatively low arterial pressures ranging above 110.

Control of Low Pressure.

Touching control, low pressure cases fall into three groups:—

1. Those who require no treatment. The acquired class including many athletes who present no symptoms, and in whom the diagnosis is made solely by the sphygmomanometer, fall into this group, as well as those apparently fit for all ordinary affairs of life, and particularly for those above 50 in whom low pressures are often salutary.

2. Those in whom treatment is usually ineffective. With increasing knowledge this group becomes smaller. It includes diatheses, such as status lymphaticus, infantilism, myasthenia gravis, adiposis dolorosa, &c., which appear to rest upon a basis of disordered

endocrine function. Certain of these may be relieved by hormone therapy.

3. Those in whom treatment is required:—

(*a*) *General Measures.*—Daily life should be so regulated as to conserve energy and to raise the standard of vitality. It is a mistake to try to raise pressures too rapidly. In the former case metabolic balance may be still further upset, whilst in the latter throbbing in the head, followed by irritability, may be induced. Seldom is it necessary, or even possible, to raise pressures to any great extent. Experience shows that a rise in pressure of only a few millimetres makes all the difference between comfort and discomfort. One should be content gradually to raise pressures to and maintain them at a level which appears to be the optimum, checking results by readings at regular intervals. Diet should be nourishing, balanced, and easily assimilable. A sufficiency of vitamins should be ensured. In addition to ordinary drinks, a pint of water for each 5 st. of body-weight should be taken daily. As a general rule alcohol is best avoided, but in cases of gastric neurasthenia, or anorexia due to mental or physical exhaustion, a little stimulant with meals tends to restore vital balance. For exhaustion bed is indicated, followed by rest after the chief meals, and by early hours. Exercise should never be persisted in till breathlessness, palpitation, or other symptoms supervene. Horse-riding and dancing, within moderate limits, by sending up arterial pressure to more standard levels, act as beneficial stimuli. Excessive exertion depletes vitality and drops pressures to levels of discomfort. Graduated exercises, at first on the level and later on prescribed gradients, favour oxidation and counteract respiratory deficiency. These objects are also furthered by physical exercises of stretching and bending, in combination with deep breathing. For most hypopietics who live in cold, damp, and changeable climates holidays and sunshine are beneficial. The craving for sunshine is often greater than that for food.

(*b*) *Special Measures.*—Relaxation, passive movements, massage with graduated resistance exercises, ultra-violet radiation, static electricity, oxygen foam baths or injections, and hydro- and balneo-therapy all have their appropriate uses. In the majority of cases of hypopiesis endocrine dysfunction is present. Thyroid gland should not be given in too large doses, otherwise further instability may be added. It should be combined with other glands in accordance with definite indications. Next in importance comes the pituitary. Whole gland, in doses up to two grains, thrice daily is given until slight throbbing in the head or palpitation point to the limit of tolerance. Thereupon the dose should be reduced by half, continued for several weeks in accordance with pressure readings. A convenient method of giving posterior pituitary is by an intranasal spray. As pitrescin it may be given hypodermically. Whole gland pituitary and suprarenal when administered by mouth are best prescribed with a coating so as to render these glands insoluble in the gastric juice. Pure suprarenal crystalline substance (tab. supramedulla) is active by mouth, and may be given in dosage of gr. 1/1000 up to gr. 1/100 twice daily. Pluriglandular syndromes may originate in disorders of the gonads, but up to now I have found no testicular or ovarian preparation to fulfil its promise. Most parathyroid preparations by mouth are inert, parathormone hypodermically or intramuscularly being the only one that yields appreciable results. As regards drugs, ephedrine is one of the most generally useful. It possesses low toxicity and stimulate cardiac action, at the same time increasing basal metabolism and urinary output. The usual dose is gr. ½ in tablet form by mouth, or hypodermically if more rapid action is desired. For emergencies, cardiazol or coramine are serviceable. In cardiac failure, nothing equals standardised preparations of digitalis in sufficient amount. Similarly with auricular fibrillation, quinidine being also useful in certain of the more chronic forms if cautiously administered.

In acute infections low arterial pressure is brought about by a combination of vasomotor paresis with myocardial weakness and hormonic depletion. Treatment should be directed to whichever of these factors is in the ascendant. After diphtheria, influenza, and pneumonia it is essential that during convalescence the heart shall be given prolonged rest. For rheumatic fever rest must be continued for three months or even longer, otherwise a state of permanent low pressure may be entered upon.

ANNUAL MEETING IN MANCHESTER.

(Continued from p. 774.)

SECTION OF PHYSIOLOGY AND BIOCHEMISTRY.

PHYSIOLOGICAL TESTS OF RENAL FUNCTION.

Prof. H. S. RAPER (Manchester) being in the chair, Prof. E. B. VERNEY (London) opened the discussion by defining tests of renal function as observations of the response of the kidney to stimuli superimposed upon that which it is already receiving, and interpreted in terms of renal reserve. Renal reserves, he said, were *structural*, in that there was a large excess of renal tissue over and above that which was competent to carry on the excretory work during resting metabolism, and *functional*, represented by an inherent and variable capacity for the performance of increased work. He briefly reviewed the work of A. N. Richards and his colleagues which so clearly establishes the existence of these reserves, which, he held, constituted a first line of defence against the inroads of disease. First, as the work demanded of the kidney increased more units (glomeruli plus tubules) would become active and the rest pauses would be diminished. As the work demanded of each unit increased further its commencing failure would be reflected in changes in the composition of its secretion, a change exhibiting an approach towards the composition of blood plasma, such as is seen in the polyuria of chronic nephritics. This change in composition indicates a drain on functional, as against merely structural, reserves, and is probably initiated by a change in the glomerular capillary pressure.

An analogy was here suggested, said Prof. Verney, with the work of the heart as observed in the Starling heart-lung preparation, and he went on to develop the comparison between right auricular and glomerular capillary pressures. In the kidney, however, the work is osmotic in character, and to all intents a kidney engaged in producing a urine having the same composition as the protein-free filtrate of the blood plasma is doing no work; failure is complete. As Rose Bradford had demonstrated, a diminution in the amount of kidney substance led to an increase in the urine production of the remaining tissue. Similarly, a diminution in the anatomical reserves of the kidney was partially or completely compensated by an encroachment upon its functional reserves. Further guidance in the interpretation of a case was afforded by the facts that the excretion of urea and the substances eliminated by a similar mechanism was dependent mainly upon the *amount* of kidney substance, that of chloride mainly upon the *rate* of urine flow.

In renal failure there were theoretically three types to be considered: (1) that due to a severe diminution in the number of renal units; (2) that due to a fall in the magnitude of the pressure stimulus; and (3) that due to impairment in the tone of the secretory units, and possibly there was a clinical parallel to all three of these, or all might be involved together. Caffeine had been shown to affect the number of effective glomeruli and the pressure stimulus, and much might be learnt from the response to its exhibition under controlled conditions. The surest indication of renal function would, he concluded, be given by administering urea or some such substances as phenol red, and comparing the elimination in a given time at any given concentration in the blood plasma with that of the normal. Any assessment of renal reserve was, however, fraught with difficulty.

Discussion.

Sir WILLIAM WILLCOX (London) said he regarded the information given by blood-urea determinations as most useful, especially in colon bacillus infections, and in chloroform and alcohol nephritis, but we must remember that the blood-urea concentration might be high without serious import. The indigo-carmine test was useful, but he did not use phenol-sulphone-phthalein as he had found that its excretion might be identical with that in the normal subject in a patient at the very onset of uræmia. Observations on the rate and concentration of chloride excreted were of great value. He had found caffeine citrate useful for a short time only, a few days at the most. There was no doubt, though it was liable to be overlooked, that uræmia might be purely cardiac in origin instead of being due to damaged kidneys.

Prof. E. C. DODDS (London) said that in assessing the value of a test we must ask ourselves to what aspect of kidney function the test was directed. The tests were of value in estimating the extent of the lesions in chronic nephritis, with or without œdema, in albuminuria prior to the administration of an anæsthetic, and in renal dwarfism. He recommended the estimation in the blood of urea, non-protein-nitrogen, cholesterol, and total protein, these last two being especially helpful in the œdematous type of nephritis. Patients with low cholesterol and total protein responded well to a high protein diet. As an aid to prognosis in cases of uræmia he recommended the estimation of blood calcium and phosphorus. He would like to emphasise his view that the mere estimation of blood-urea was liable to lead to a fallacy, if a look out was not kept for dehydration, which alone might account for a blood-urea of over 100 mg. per 100 c.cm. An estimation of the total solids of the blood in such a case might show a rise from 20 to 28 per cent. As regards urine analysis, if the urea reached 2 per cent. or over gross renal changes might be regarded as excluded.

Prof. J. SHAW DUNN (Manchester) described the results of his observations on animals, both normal and diseased. He had so far failed to produce experimentally the equivalent of human nephritis. In man the damage was usually glomerular at first, in animals there was a tubular necrosis affecting urea excretion, but water and chloride excretion was not affected till later, with the onset of œdema. He had repeated Frankson's work on urea excretion, urea being given by the mouth, and was able thus to induce the non-drinking rabbit to become a water-drinker for the elimination of the urea. In animals with nephritis urea by the mouth caused a large rise in blood-urea when on a dry diet, but no rise in urinary urea, and it was clear that the rise in blood-urea was greater than could be accounted for, as Prof. Dodds had suggested, purely by a concentration of the blood. He would like to stress the importance of free water-supplies for the excretion of urea, and the value of dry diet as a test of urea excretion.

Mr. H. D. KAY said that a simple and conclusive test, devoid of ill-effects on the patient, was still to found, but that the glycerophosphate test, which had now been tested on 70 cases at the London Hospital, had definite advantages over the urea-concentration and phenol-sulphone-phthalein tests. The principle of the test lay in the estimation of the excess phosphate excretion after the administration of sodium β-glycerophosphate, a chemically pure substance which was cheap and easily obtainable, harmless, and sterilisable. The routine of the test was as follows: At 8 A.M. the bladder is emptied, 400 c.cm. of water or weak tea is taken, and at 9.30 A.M. 10 c.cm. of a sterile 8 per cent. aqueous solution of the drug, corresponding to 550 mg. of phosphate, is given intravenously. The urine is taken in an hour, and its phosphates estimated after precipitating the proteins. The excess of phosphate may vary from nil (in chronic nephritis) to 250 mg. or more. After a solution had been prepared only two urinary analyses were required, and these could be satisfactorily performed by any sensible laboratory attendant. There was no decomposition of the substance to be estimated if the analysis could not be done at once, and the test was independent of the volume passed and unaffected by urinary pigment or blood. Their results so far had been as follows:—

1. A normal subject excretes at least 150 mg.
2. If there be less there is renal involvement, which varies inversely as the amount excreted.
3. The test compares favourably with any other test as regards the correspondence of its finding with the whole clinical picture.

Mr. J. B. MACALPINE (Manchester) spoke as a genito-urinary surgeon who was using these tests constantly. Estimation of the blood-urea, he found, brought precision to his knowledge, and was a great help as a supplement to the clinical picture. He regarded the tests as widening the rungs of the uræmic ladder; for example, before a prostatectomy he carried out bladder drainage until the blood-urea fell below the 40 mg. level. Sometimes the drainage provoked a profuse polyuria. He had got over 200 ounces from one case within 12 hours. This polyuria, when extreme, was an unfavourable omen, tending to end with a fatal anuria. As regards tests of the separate function of the kidneys this was a cystoscopic problem, and he liked the indigo-carmine test because it was simple, quick, and avoided ureteral catheterisation. He was unwilling, where it was avoidable, to catheterise a possibly aseptic kidney through a septic bladder, and he was not a strong believer in the quantitative value of the urea-concentration and phenol-sulphone-phthalein tests because he had satisfied himself that urine escaped around the average ureteral catheter. Mr. Macalpine also dealt with the problems of hypertrophy and the great value of pyelography, especially in stone, and particularly where a stone was seen on one side and the other kidney seemed to be inactive.

Dr. F. H. SMIRK (Manchester) described the effects on the normal and the nephritic of the administration of water, urea, and caffeine by the mouth. In the nephritic the loss of water was slow and delayed, and, after urea, the urinary urea concentration might even fall. After urea the sodium chloride excretion rises in the normal but not in the nephritic, and of 22 normals examined 18 had above 0·8 per cent. sodium chloride, while of 60 nephritics only 4 had above 0·8 per cent. He had tried giving grs. 5 of caffeine by mouth as a routine test, and found this increased the chloride excretion out of all proportion to the other constituents. The urea increase was less marked. Caffeine caused a greater rise in chlorides than urea did.

Prof. E. P. POULTON (London) took Prof. Verney to task for not developing, from his extremely valuable observations on kidney function, a physiological theory of Bright's disease. To the glomerular filtrate, which could be increased by caffeine, the tubule added urea and subtracted chloride and (at a more distal point) water. Bright's disease was primarily due to impervious glomeruli. He did not approve of Calvert's test, and thought that half the value of the urea-concentration test was lost if the total excretion was not considered as well as the concentration.

Mr. J. SWIFT JOLY (London) thought that, from the surgeon's point of view, an excretion of 1 gramme of urea per hour was satisfactory. He agreed with Prof. Poulton that for this water was necessary.

Reply.

Prof. VERNEY said there was so much disagreement as to the precise location of the functions of the kidney in the organ itself that he preferred not to dissociate entirely glomerulus and tubule. He had been very pleased to hear of the use of the caffeine test by Dr. Smirk, and was full of admiration for Mr. Kay's contribution to the discussion.

SECTION OF PUBLIC HEALTH.

HUMAN TUBERCULOSIS OF BOVINE ORIGIN.

Dr. W. G. SAVAGE (M.O.H., Somerset), in opening the discussion, estimated the human deaths caused annually by the bovine tubercle bacillus at 2000 to 2300. Most of them were the deaths of children, and we had no knowledge as to how many non-fatal infections occurred. As to the extent of bovine tuberculosis among cattle in this country, he thought that about 40 per cent. of the cows were infected; that about 1 per cent. of the cows were "open" cases; and that about 0·3 per cent. had tuberculosis of the udder. He passed on to consider methods for the reduction of the prevalence of tuberculosis in cattle under five heads:—

(1) *Elimination of all tuberculous cattle*—viz., by the destruction of reactors. This could be done successfully in small areas—e.g., the Channel Islands. It was the official plan in the U.S.A., where 207,830 tuberculous cattle were slaughtered in 1927. The average percentage of reactors in the U.S.A. was only 8·3, and it would be impracticable in England with more than ten times that percentage of reactors to adopt the elimination plan.

(2) *Building up of herds free from tuberculosis.*—The procedure advocated by Prof. Bang was theoretically easy, but there were many administrative difficulties, and the method even in Denmark had not made the progress that was expected. The same principle had been followed in England with regard to Certified and Grade A (T.T.) milks, but the increase in the number of herds, which produced these two designated milks, had been slow. At the end of September, 1928, there were only 152 Certified and 207 Grade A (T.T.) milk producers—an entirely insignificant proportion of the whole. In Somerset, with at least 7300 producers, there were only 11 producers of these two types of milk at the end of 1928. This method could not, therefore, be regarded as a practical solution of our problem.

(3) *Elimination of particular classes of tuberculous cows.*—Theoretically we could reduce the infection among bovines and the risk to humans if we eliminated all infectious cows. In fact, however, partly from administrative but mainly from scientific difficulties these animals were not removed from the herds as soon as they became "open" cases, but only after they had done most of the harm they were capable of doing. The discovery of the infectious cases was not being followed up by a systematic examination of the other animals, and the cases of tuberculosis of the udder were not being detected until after the milk-supply had been affected for long periods. Systematic veterinary inspection was being urged as a means for the reduction of the amount of bovine tuberculosis. The first difficulty was that the ablest veterinary inspector could not detect infectious animals in their early stages, and the second difficulty was that financial considerations severely limited the frequency of inspection. The third difficulty was: Would the removal of some of the infection in the case of physiologically overlooked cows play any decisive part in reducing the amount of bovine tuberculosis? The figures available from places where routine inspection has been in vogue for years did not show any such reduction. He estimated the cost of an adequate system of veterinary inspection at about £300,000 a year, and was of opinion that veterinary inspection must stand or fall on its merits as a means of reducing bovine tuberculosis. The onus was on their veterinary friends to demonstrate that veterinary inspection could bring about such a reduction. If it could, it was a true preventive measure and worth the price.

(4) *Measures directly aimed at reducing the amount of tubercle bacilli in milk.*—When milk was found to contain tubercle bacilli, it was feasible in something like 60 per cent. of the cases to find an infective animal and eliminate her, but only an insignificant proportion of the milk-supply was tested for tubercle bacilli, and after the expenditure of public money in searching out the cow with the tuberculous udder the farmer was in no way penalised, but, on the contrary, received compensation for the cow. Pasteurisation of the milk-supply would probably largely eliminate the dangers of tuberculous milk. Its adoption would be a confession of failure, and the acceptance of the second-best.

(5) *Immunisation of cows against tuberculosis.*—Calmette's vaccine was on trial, and should be very fully tested, but the latest results were not very favourable.

After considering the various remedies advocated, Dr. Savage went on to summarise his suggestions. Routine veterinary inspection as a thing by itself he considered was not worth doing, but it occupied quite a different place as part of a comprehensive attack on bovine tuberculosis. The cow should be kept under much more open-air conditions. A more active educational campaign must be undertaken. Part of the onus of preventing the spread of infection must be put on the cow-keeper. Feeding problems and other factors likely to affect tuberculosis must be carefully considered. In such a comprehensive scheme immunisation experiments, the formation of tubercle, free herds, the operation of a modified Tuberculosis Order, and the routine veterinary inspection of cows will all find a place. If the agricultural community was not prepared to coöperate actively in the schemes of the State, and of local authorities for reducing the incidence of bovine tuberculosis, pasteurisation seemed less of an evil than "the present tinkering procedures." He himself, however, favoured the adoption of a comprehensive scheme such as he had indicated.

Discussion.

Colonel J. W. BRITTLEBANK (Chief Veterinary Officer, Manchester) thought that Dr. Savage was unduly pessimistic. He estimated the loss to agriculture through bovine tuberculosis at £1,000,000 annually. He thought something had been done to reduce the incidence of tuberculosis by veterinary inspection in Manchester from 1904 onwards. The West Riding, Cumberland, and Durham had all adopted veterinary inspection, and such schemes should not be limited to inspection, but include feeding, housing, management, &c.

Mr. A. GOFTON, M.R.C.V.S. (Edinburgh), thought Dr. Savage's figures of the incidence of bovine tuberculosis were too low, and that the percentage of cows with tuberculous udders in Edinburgh was nearer 0·5 than 0·3. The designated milk scheme had made a great appeal to the agricultural community, and the safe milk in question, in both Edinburgh and Glasgow, very largely went to the children who were most at risk. He regarded the Tuberculosis Order as purely a public health measure, and he believed that the Order and veterinary inspection had been instrumental in bringing about a reduction in the incidence of tuberculosis among Edinburgh children.

Dr. F. H. MORISON (M.O.H., Cumberland) thought that 5 per cent. of the cows had diagnosable tuberculosis. He referred to the dope use of tuberculine, and to the difficulty in maintaining herds free from tuberculosis. He had found Certified milk highly infected with tubercle bacilli. The graded milks were a failure, and pasteurisation was only doubtfully safe. He believed that milk dried by the roller process was the best solution, and he looked forward to the establishment of milk-drying factories throughout the country.

Dr. T. EUSTACE HILL (M.O.H., Co. Durham) said that his county had just appointed a chief veterinary surgeon and four whole-time assistants. They would both inspect the cattle and preach sanitation. He anticipated an enormous improvement in the sanitation of the cow-sheds as a result. When milk samples were found to be tuberculous they usually succeeded in finding the offending cow. They had found the direct microscopical test quite useful in saving the delay incidental to the biological test.

Dr. MIDDLETON MARTIN (M.O.H., Gloucestershire) said that their cattle were examined every half year by part-time veterinary surgeons, but that they seemed to get the same percentage of emaciation, &c., at each inspection.

Dr. VEITCH CLARK (Manchester) stated that they had succeeded in maintaining a tubercle-free herd for supplying the local hospitals.

Reply.

Dr. SAVAGE remarked that Colonel Brittlebank had not answered his question as to the resistance to infection of a physiologically overworked cow. If inspection was to be adopted it must be thoroughly done, and at least every quarter, and, of course, if the cows were out at grass, it was the farmer's business to bring them in for the inspection.

SECTION OF ANÆSTHETICS.

SPINAL ANÆSTHESIA WITH SPINOCAIN.

Dr. GEORGE P. PITKIN (New Jersey, U.S.A.) gave an account of the experimental work done by himself and his co-workers in producing what he claims to be a controllable spinal anæsthetic. They set out, he said, to produce a spinal anæsthetic that would minimise toxic reactions, be certain in effect, constant in duration, act in direct ratio to the amount of anæsthetic agent injected, and be without effect on the heart action, vascular tension, and respiratory function. The chief factor in the control of a spinal anæsthetic being to prevent its diffusion in the subarachnoid space, they had tried to find a substance which would prevent this diffusion until the anæsthetic had been absorbed. They had evolved what, for the lack of a better name, was called amyloprolamin; it was derived from gliadin, the mucilaginous content of wheat starch. They had also determined the capacity of the dural sac at various heights in adults and in children of different ages. Novocain was chosen from the other drugs used in spinal anæsthetics as giving a complete anæsthesia of the sensory nerves, affecting the tactile and muscular sensation only slightly, not increasing the cell count of the spinal fluid, and not raising the intradural pressure. Faulty technique was responsible for the production of hypotonic headaches, which were more often seen when the puncture was made with the patient sitting up, owing to the greater amount of spinal fluid lost. To prevent extensive trauma of the dura the use of needles of small gauge with a short bevel was advisable. As a result of these experiments and reports on over a thousand inductions they were now justified in asserting that spinocain was controllable within the dural sac. This method of producing spinal anæsthesia had been developed as a protection to the surgeon, owing to the difficulty of procuring expert anæsthetists, the large proportion of anæsthetics in the United States being given by nurses who were merely technicians. He considered it important that the technique of giving spinocain should be in expert hands. Dr. Pitkin concluded by showing on the screen the essential points of his method.

Dr. FRANK A. KELLY (Detroit) limited himself to the clinical aspects of controllable anæsthesia. He said that Dr. Pitkin's technique had negatived all previous objections to spinal anæsthetics. The transitory nature of the anæsthetic had been corrected by the addition of a mucilaginous substance, the height and extent of the anæsthesia was controlled by the tilting of the table, the depression in blood pressure—so often a serious objection in the past—was prevented by the preoperative injection of ephedrine. Another safety factor of great importance was the use of the lighter gravity solution, for if a serious fall in blood pressure occurred the head of the table could be lowered so as to prevent cerebral anæmia. What they called low anæsthesia was a true sacral or caudal anæsthesia where only the perineum, vagina, and rectum were involved, together with the saddle area on the inner side of the thigh. In order to obtain this, one-half of an ampoule of spinocain was injected at the fourth lumbar interspace, and the patient immediately tipped into at least a 15° Trendelenburg position, the degree being reckoned by Dr. Pitkin's tiltometer. What they called high anæsthesia extended to the costal arch, and was obtained by injecting the anæsthetising agent into the first lumbar interspace and mixing it with 6 c.cm. of spinal fluid: when this anæsthesia extended to the costal arch it was considered complete, and the patient was placed in the Trendelenburg position to stop the upward extension. His experience in doing very high abdominal work was that if the anæsthesia was carried to a level high enough to allow the operation to be completed without difficulty, some patients complained of difficulty in breathing and a feeling of weakness. It was therefore his practice to limit the spinal anæsthetic, and to supplement it with an intercostal block of the eighth, ninth, tenth, and eleventh costal nerves at the angle. Ephedrine before the spinal injection prevented any fall in blood pressure; the drug, given intramuscularly or subcutaneously, acted as rapidly as when it was given intravenously, in contrast to adrenalin which, in skin or muscle, caused a local ischæmia, but was quickly absorbed intravenously, though its action was transitory. In a cinema demonstration Dr. Kelly showed points of technique, including a common fault in the position of the patient, resulting in a "corkscrew spine." He demonstrated the presence of peristaltic action during an abdominal operation under spinal anæsthesia, and explained it by the unopposed action of the sympathetic and vagal nerves, due to the blocking of the vasomotor nerves. Barbital, he said, was regarded as an antidote to novocain poisoning, but he had never had occasion to use it.

Dr. E. FALKNER HILL (Manchester) agreed that Dr. Pitkin's method did away with previous objections to spinal anæsthesia. From his own experience of the method, however, he was inclined to think that there was some fall in blood pressure due to operative procedure, but this was not a bad thing for the patient. He gave illustrations from bad surgical risk cases in some of which he had given chloroform and ether as well. He did not think that strychnine should be included in the anæsthetic solution, as it increased the irritability of the spinal canal.

Dr. A. L. FLEMING (Bristol) said he hoped Dr. Pitkin and Dr. Kelly might come to give their patients the benefit of inhalation anæsthetic as well. Peristalsis, he thought, was not always inhibited under an inhalation anæsthetic; he had seen it on one or two occasions.

Dr. K. B. PINSON (Manchester) gave his experience of stovaine and novocain anæsthesia; he had had only 55 per cent. of complete success on all counts, from the point of view of patient, operation, and recovery. He was much struck by the absence of shock with this method. He considered that 45 per cent. of failures made the use of spinocain something of an experiment; they might have been due to the human response to novocain. An improvement in the solution might obviate the difficulties.

Dr. W. SALISBURY (Northampton) narrated his success with stovaine and glucose in shock-producing operations. He always used the heavy solution, and attributed his success to attention to small points of technique.

Dr. DONALD said he had had a happy experience of spinocain in some cases; his six partial failures were all in young virile men with acute appendicitis. He thought that women and patients with lowered resistance did better under spinocain. He found it difficult to decide whether the good effects he noted were due to the spinocain or ephedrine.

Dr. E. A. **Gerrard** (Manchester) gave an account of the use of spinocain in obstetrical work, noting the ease with which the cervix dilated, the extreme relaxation of the perineum, and the delight of the patient. The parturient woman could bear down better, because the pressure of the head on the perineum was not too painful. For instrumental delivery he advised that the anæsthetic should be carried higher than the sacral or caudal type; pituitrin should in any case be used with care.

Demonstrations.

Dr. G. A. **Schwartz** (New York) gave a demonstration of the apparatus used in intratracheal anæsthesia and resuscitation by the Flagg method. He showed on the screen the intubation of the larynx by a flexible catheter, and a simple method of maintaining the anæsthesia by fixing a tube connected with the catheter to a can of ether. He also demonstrated on the screen the resuscitation of a new-born child with oxygen and carbon dioxide through a pharyngeal tube.

Dr. F. L. **Richardson** (Boston, U.S.A.) gave a cinema demonstration on the teaching of anæsthetics. The student, he said, should be taught to give one or two drugs well; it was not possible to teach everything by the film, but important points could be brought out by slowing down the projection. The demonstration included the administration of spinocain and ether vapour.

Avertin.

Dr. G. **Edwards** (London) read a paper on the use of avertin or tri-brom-ethyl-alcohol, a white crystalline solid, soluble in water to the extent of 3½ per cent. at body temperature. Introduced in solution into the rectum it was readily absorbed, appearing in the urine in combination with glycuronic acid. Avertin was a basal narcotic; once a patient was under its influence only a very small quantity of inhalation anæsthetic was required to make the anæsthesia complete. The anæsthetic could be given in the ward without fuss, induction was gradual, and though the narcosis had been light there was no memory of anything unpleasant. Avertin was of particular value in dealing with highly nervous patients, with cases of Graves's disease, and with children. Avertin was contra-indicated in ulcerated conditions of the rectum and colon, in the presence of severe renal and hepatic disease, acidosis, and serious blood diseases. On the other hand, cases of hyperthyroidism tolerated massive doses of avertin and could eliminate them quickly. The fall in blood pressure was usually within the limits of that observed in deep sleep, between 10 and 30 mm. Hg. The respiratory centre was depressed, and a slight cyanosis was usually observed, more particularly after a preliminary dose of morphia. Marked cyanosis did not occur if the dose had not exceeded 0·1 g. per kilo of body-weight, and the airway was kept clear. Anæsthesia took 20–30 minutes to reach completion, the ocular reflexes disappeared in the usual way, and a skin reflex might remain. A sudden blast of strong ether vapour might produce a cough—a useful preliminary test to determine how much inhalation anæsthetic would be needed. The actual administration was simple; some observers thought it good to give a sedative overnight. The usual duration of narcosis was 1½–2 hours from the time of injection; about four hours from the start the patient was usually quite conscious. In only one case had he seen any trouble directly due to the avertin anæsthesia; in this case[1] the patient died 20 hours after the administration of a dose at the rate of 0·125 g. per kilo. Probably a deficiency of thyroid secretion had diminished the power of detoxicating and eliminating the drug. In delayed return to consciousness the respiration might be stimulated by injection of lobeline or inhaling carbon dioxide and oxygen, the circulation by injections of ephedrine.

Dr. E. F. **Hill** (Manchester) suggested that avertin, combined with spinal anæsthesia, would be an ideal anæsthetic.

Dr. H. P. **Fairlie** (Glasgow) described a case in which the patient did not respond well to avertin, but with gas-oxygen the operation went off well. The trouble with avertin began six hours after operation, when there was intense rectal irritation with diarrhœa and passage of mucus. He considered the death-rate with this method was unduly high.

Reviews and Notices of Books.

PHYSIOLOGY.

Bainbridge and Menzies' Essentials of Physiology. Sixth edition. Edited by H. **Hartridge**, M.A., M.D., Sc.D., F.R.S., Professor of Physiology, University of London. London: Longmans, Green and Co. 1929. Pp. 497. 14*s.*

Elements of Physiology. By E. G. **Martin**, Ph.D., Professor of Physiology, Stanford University, California; and F. W. **Weymouth**, Ph.D., Associate Professor of Physiology in the University. Philadelphia: Lea and Febiger. Pp. 784.

The sixth edition of Bainbridge and Menzies' "Essentials of Physiology" has been revised and brought up to date by Prof. Hartridge. The book retains its original character—that is, it gives in a clear, dogmatic manner a brief but adequate account of human physiology. Certain sections are perhaps too brief—for example, the section on reproduction. Prof. Hartridge has, however, found space to mention a great deal of new work without materially increasing the size of the book. The new chapters on exercise and work, and on the nervous system are excellent—the diagrams in the latter being particularly good. Unfortunately, a few mistakes have been allowed to creep in—for example, on p. 495 we read that "Parkes and his co-workers have extracted from ovarian tissue a substance 'œstrin' which causes menstruation when injected into the blood," whereas, of course, it does not. The use in the index of thick type for the principal subdivisions under each letter facilitates quick reference to any subject.

Dr. Martin and his colleague have written their book with the object of expressing a point of view rather than that of teaching examination students. They explain in their preface that they have tried to present the subject of physiology "by development of two key-principles." The first consists in the application of physico-chemical laws to physiological processes, and the second is that "every protoplasmic cell is inherently a self-sustaining system." The book is divided into four chief sections, the first two of which contain material usually found in works on general physiology. It is written with little regard for economy of words; moreover, these tend to be arranged in sequences which seem strange to English readers. The second section of the book deals more systematically with human physiology. It is, however, very unequal, and the arrangement makes it difficult to read. For example, the section on the respiratory system does not mention hæmoglobin—for that we must turn to the earlier section on general physiology; in the section on digestion, the pancreas is discussed without mention of insulin, and here, too, we must refer back to the earlier section for complete information. Great prominence is given to the special senses, at the expense of other subjects; the section on the special senses contains 216 pages, that on the central nervous system only 45. From these examples it will be seen that the "key-principles" have not enabled the authors to give us a very clear general view of physiology.

RECENT ADVANCES IN SURGERY.

Second edition. By W. H. OGILVIE, M.A., M.D., M.Ch. Oxon., F.R.C.S., Assistant Surgeon, Guy's Hospital; Surgeon to Out-patients, Hampstead General Hospital. London: J. and A. Churchill. 1929. Pp. 495. 15*s.*

THE revision of this useful book has been well done, and the reader who depends upon one manual to keep him abreast of surgical thought will find that the author has not failed to record any of the important advances in surgical science since the first edition was published. Even more assiduous readers of surgical literature will be grateful for the admirable summaries of various topics of interest here set out. The book is more than a record of new surgical methods, good or bad; it is a discriminating account of what has happened in recent years and well deserves its title. Its compilation must have been difficult. Certain omissions and occasional evidence of reluctance on the part of the author to give adequate prominence to views or methods which he regards unfavourably are not wanting. But generally he has shown wise judgment both in his selection of material and in the manner of its presentation.

TREATMENT OF RHEUMATOID ARTHRITIS.

By A. H. DOUTHWAITE, M.D., F.R.C.P. Lond., Assistant Physician, Guy's Hospital; Honorary Physician, All Saints' Hospital. London: H. K. Lewis and Co., Ltd. 1929. Pp. 80. 6*s.*

PRACTITIONERS will find this an interesting and useful book. The author skilfully avoids the dogma of any extreme school of thought and sets out the known facts of an obscure subject with clarity. On the question of focal sepsis he is eminently sane, and in dealing with treatment he has not overlooked the need for practical advice on such subjects as climate and the correction of deformities. These are of great importance but are often neglected when the treatment of rheumatoid arthritis is being considered. On the endocrine factor and on metabolic features of the disease his views would invite comment in another connexion, but the interest of these matters is too academic to justify criticism of a book which is essentially practical.

GYNÆCOLOGY.

By LYNN LYLE FULKERSON, A.B., M.D., F.A.C.S., Instructor in Obstetrics and Gynæcology, Cornell University Medical School. Philadelphia: P. Blakiston's Son and Co. 1929. Pp. 842.

THE scope of gynæcology in America extends to the urinary system, the lower bowel, and the lower abdomen generally, and the impression given by this book is that gynæcology as we know it is to be correlated with diseases of the urinary tract and rectum rather than with the physiology and pathology of parturition. This attitude finds no favour in this country, but that will not prevent this work, which includes operations on the intestines and abdominal wall, from finding interested readers among general as well as gynæcological surgeons. The systematic teaching given by Dr. Fulkerson is clear and up to date, and many erroneous statements which make their wearisome appearance in successive editions of well-known books are corrected. For example, chronic endometritis is correctly described as a rare disease. In America radium has entirely replaced operation in the treatment of carcinoma of the cervix, and the radical operation is considered to be so obsolete that it is not even described here. On the other hand, some of the operations advised are seldom, if ever, performed in this country, particularly the exploration of the pelvis through the anterior and posterior fornices of the vagina.

Rather less than half the book is devoted to operative surgery. A good deal of space is wasted on the author's methods of sterilisation and theatre management. Many useful points are to be gleaned from the operations for displacement and prolapse of the genital tract which include George Gray Ward's technique for prolapse of the pouch of Douglas and rectocele. The author seems to like ligaturing pedicles by means of continuous sutures. A method of performing hysterectomy in which not only are all the vessels ligatured by one continuous suture, but the pelvic peritoneum is closed by the same suture, seems on paper to be a risky procedure. Myomectomy through the anterior fornix is not likely to be practised by British gynæcologists; it appears to have every disadvantage and no advantage over addominal myomectomy. There are over 600 illustrations in this book and they are exceptionally clear and apt.

THE STUDY OF PHYSIC.

An Introduction to the Study of Physic. By WILLIAM HEBERDEN. Prefatory essay by LEROY CRUMMER. New York: Paul B. Hoeber; London: Humphrey Milford, Oxford University Press. 1929. Pp. 159. 10*s.* 6*d.*

DR. Crummer here prints, for the first time in book form, the manuscript of the elder Heberden's introduction to the study of physic and gives a reprint of the same author's classical account of angina pectoris—the whole being a reprint, with additions and corrections, from "Annals of Medical History" (Vol. X., Nos. 3 and 4, 1928). The author was lucky enough to discover in a second-hand London bookshop three manuscript volumes, one of which was the introduction to the study of physic in Heberden's holograph, and with his signature at the end of the preface. Comparisons with known Heberden manuscript at the Royal College of Physicians of London made it quite clear that this is a genuine Heberden item, and while congratulating the author on his good fortune, we may thank him sincerely for giving us the contents of a book by a very celebrated English physician, about whom we have always wished to know more. Heberden appears to have written the book for the benefit of any of his children who might contemplate taking up the study of medicine. It contains much shrewd advice as to what books to read and what practical studies are to be undertaken. Heberden's spelling is expressly preserved, but one or two odd mistakes have been overlooked in passing the essay through the press; Heberden was, we think, too good a classical scholar to have written "Demonsthanes" for Demosthenes, and there is a sad hash of Homer's description of Machaon on page 71. These slight blemishes do not detract from the value of this book as an addition to medical history. It is enriched with a fine representation of Beechey's portrait of Heberden, facsimiles of the preface to the book, and a letter from Heberden to William Hunter, the title page of the "Commentarii," and other illustrations.

ACUTE INFECTIOUS DISEASES.

Second edition. By JAY FRANK SCHAMBERG, A.B., M.D., Professor of Dermatology and Syphilology, University of Pennsylvania; and JOHN A. KOLMER, M.Sc., M.D., D.P.H., D.S.C., LL.D., Professor of Pathology and Bacteriology, University of Pennsylvania. London: Henry Kimpton. Pp. 888. 50*s.*

IN view of the mass of new knowledge accumulated during recent years on the acute infectious diseases this text-book has been thoroughly revised. Although a third of its bulk is devoted to the study of vaccination and small-pox, this volume deals minutely with the diagnosis and treatment and general care of practically all the infectious diseases met with in this country. One important omission is enteric fever, a disease which, though happily rare nowadays, is still worthy of a place in such a work as this. Many interesting tables and temperature charts are included, also 161 engravings and 27 full-page plates. All of these are excellent and lifelike; among them are pictures showing the old method adopted of holding a patient during the operation of intubation in laryngeal diphtheria. The writers themselves recommend a slightly different technique, with the patient lying down instead of sitting up in the nurse's arms. Their ideas on the feeding of intubation cases are very sound. The book is undoubtedly an excellent one and provides interesting reading. The authors quote much evidence obtained from America and from British sources in support of their opinion that small-pox is commonly spread by aerial convection. Some public health authorities in this country may agree with this view, but experts on infectious diseases are rightly sceptical on this subject. Evidence to be valid must include proof that rigid precautions have been taken to ensure that the infection could not have been transmitted through the staff of an institution. The chapters on diphtheria, scarlet fever, and measles have been largely rewritten in order to include an account of the extensive work which has been done, chiefly in America, on the treatment and prevention of these diseases. The Schick and Dick tests are clearly described, and the methods adopted—in the attempt to prevent other infectious diseases such as measles and chicken-pox—are carefully considered. The clinician will find this book useful, since the authors have made full use of the recent contributions to the literature of the subject—not only by American authorities but also by European ones—and have thoughtfully dotted the pages with many useful references.

SKIN.

Its Uses in Six Phases. By LEWIS E. HERTSLET, M.R.C.S. Eng., L.R.C.P. Lond. London: J. and A. Churchill. 1929. Pp. 206. 10*s.* 6*d.*

THIS book will gladden the hearts of the fresh-air and sunlight devotees, who from a handful of so-called cranks have in the past few years developed, the world over, into national armies whose ranks will yet engulf the faltering remnants of the overclad. It was written, the author claims (p. 107), without a headache. It is doubtful if the careful reader will so easily escape, for the information has been collected from no less than 106 essays and papers on a variety of dermatological, social, actinotherapeutic, hydrotherapeutic, and physiological subjects; all the authors receive their measure of thanks and acknowledgment in tabulated form. The skilful compounding of their statements has resulted in a veritable encyclopædia of the functions of the skin such as is contained in no single text-book hitherto published. To those with sufficient power of concentration the work will reveal new aspects of the subject. We trust it will find its way to the precincts of those who have the power to raise the blind and let in the sunshine on the commonwealth of peoples.

THE CASE OF MISS R.

By ALFRED ADLER. Translated by ELEANORE JANSEN and FRIEDRICH JANSEN, M.D. London: George Allen and Unwin, Ltd. 1929. Pp. 306. 12*s.* 6*d.*

THIS is an autobiography, beginning in childhood and leading up to the development of a compulsion neurosis soon after puberty, of a young woman. Her motives are an open book to Dr. Adler when elaborated in the light of his belief that the raison d'être of neurotic disease is the attainment of a goal by influencing the environment. The translators' preface explains that such is the way of all neuroses and psychoses, "for whose recognition and description, the theory, and for whose prophylaxis and treatment, the practice of individual psychology serves." Dr. Adler's views are marked by simplicity, in contrast to the difficulties of psycho-analytical theory, and appeal to the widespread feeling that the neuroses are nothing but unconscious malingering—an element admittedly so common that to handle it vigorously in Adler's way is often sound practice. Yet the reader, if he is familiar with cases in which symptoms are concealed by the patient and do not interfere with his task in life, may decide that Adler's individual psychology is not sufficiently individual, since neurotic symptoms can exist without the aim that he postulates as the foundation of their ætiology and the point of therapeutic attack. Except for more detailed anamnesis and explanation, Adler makes but little advance upon the medical use of morale and exhortation employed by Dejerine at the end of the last century; we can picture him using irony, severity, or kindness to urge the patient towards the renunciation of symptoms, and in this good work his certainty of belief in his own methods must give him an advantage denied to people of less confident temperament. His book will be useful to those who incline towards the methods of explanation and persuasion in the treatment of psychoneurotic disability.

A TEXT-BOOK OF MATERIA MEDICA.

Fifth edition. By HENRY G. GREENISH, D.-ès-Sc., F.I.C., F.L.S., Professor of Pharmacy to the Pharmaceutical Society of Great Britain and in the University of London. London: J. and A. Churchill. 1929. Pp. 561. 25*s.*

IN spite of the now half-forgotten depreciation of Huxley, materia medica has continued to occupy a place in medical study, and even to take on a new attraction as pharmacognosy, the generalised knowledge of such remedial agents as are selected for the purposes of a curriculum. Prof. Greenish's text-book has, for the past 20 years, been included among the really indispensable manuals. In the five years which have elapsed since the issue of the fourth edition, the work has been thoroughly overhauled; the historical introduction has been extended, and several illustrations have been added. The section on animal materia medica is not intended to deal exhaustively with anatomical features, which must be studied in other authorities.

The pattern of the work is clear and easy to follow. For example, if we turn to senna, we find (page 41) its chief constituents, and certain other substances of which the chemical constitution is specified; we are then introduced to several laxative drugs which "form a natural group allied by the similarity of their constituents" owing to the presence of oxymethylanthraquinones. An authoritative generalisation of this kind gives the student confidence; it delivers him from bondage to dry facts, and affords some inkling of the relation between chemical constitution and physiological effect.

INCOMPATIBILITY IN PRESCRIPTIONS AND HOW TO AVOID IT.

New edition, revised and enlarged. By THOMAS STEPHENSON, D.Sc., Ph.C., F.R.S. Edin., F.C.S. Edinburgh: "The Prescriber" Offices. 1929. Pp. 61. 4*s.* 6*d.*

THIS useful handbook first appeared in 1915 as a 32-page pamphlet. A revised edition and several reprints have borne witness to its acceptability, and it has now been subjected to further revision and expansion. The second half of the book, arranged in dictionary form, is easily consulted, and is likely to prevent many mistakes. Few busy prescribers, for instance, would be prepared to name off-hand the substances incompatible with mercurochrome. In a future edition two statements (on pages 47 and 31 respectively) should be modified. The well-known tincture of iodine of the French Codex, 1908, was, by ministerial decree, superseded in 1922 by a "teinture d'iode officinale," containing potassium iodide, and reduced in strength in iodine, and this important change should be made clear. Secondly, recent work by D. B. Dott has disproved the general statement that alkalis decompose acetylsalicylic acid. We find little to criticise in this work which is of proved value.

THE LANCET.

LONDON: SATURDAY, OCTOBER 19, 1929.

THE CHICAGO SURGICAL CONGRESS.

ON Monday last, Oct. 14th, the annual Clinical Congress of the American College of Surgeons was opened, and the proceedings will last throughout the week, while arrangements are outlined extending the time limits of the Congress until Oct. 30th in order to provide an opportunity for the congressists of visiting clinical centres in the environment. No more suitable city in the world exists for holding a massively attended congress than Chicago. Public buildings are on the large scale which characterises the architecture in the capital of the Middle West; the Murphy Hall, a remarkably handsome example of modern florid architecture, makes an excellent centre of reunion; such hospitals as the Wesley Memorial Hospital, the Cook County Hospital, St. Luke's Hospital, and the Montgomery Memorial Hospital afford perfect opportunities for carrying out an extensive clinical programme; while some 20 huge hotels, many of them placed within short walking distance of the headquarters of the Congress, afford accommodation at graded rates for an unlimited number of visitors.

Three addresses will be delivered in plenary congress when members can be accommodated in the ball-room of the Stevens Hotel; one by the new President of the American College of Surgeons, Major-General MERRITTE W. IRELAND, Surgeon-General of the United States Army, ushers in the meeting; one by Dr. GLENN FRANK, President of the University of Wisconsin, is directed to the convocation of Fellows; and a scientific discourse, the Murphy Oration, is delivered by Prof. D. P. D. WILKIE, professor of surgery in the University of Edinburgh, in which he reviews the present position of abdominal surgery. This oration is published in THE LANCET to-day and it is apposite that, in the city where MURPHY was so long a leading figure, the principles which at present prevail in abdominal surgery should be brought to mind. We have here a résumé of knowledge along lines where MURPHY himself made many valuable contributions, for although he traversed the whole field of his art his most fruitful energies were directed towards the improvement of abdominal surgery. MURPHY was gifted alike with remarkably clear vision, a fierce power of concentration, and boundless enthusiasm, and these qualities, which characterise all his work, were nowhere better exemplified than in his early endeavours to extend the range and improve the technique of operative procedure in connexion with the abdomen. MURPHY was one of the pioneers in the brisk and important development of American surgery which became so marked some 20 years ago, and his name occurs among the first Board of Regents of the American College of Surgeons, now engaged in its nineteenth annual session. The College derived much of its initial plan from the constitution of the Royal College of Surgeons of England, and acknowledged this indebtedness by inviting Sir RICKMAN GODLEE, then President of the English College, to be present at its first congregation held on Nov. 13th, 1913, at Chicago. A fundamental difference between the English and the American body is the absence, in the latter case, of strict examinational tests; but an elaborate system of scrutiny has been designed to keep the list of Fellows up to the standards demanded by the College, while the machinery of the College has been used, to great practical advantage, as a lever for securing proper surgical provision at provincial hospitals.

The subjects selected at the Chicago Congress for the operative clinics and demonstrations and the scientific symposia indicate a meeting of general and practical interest upon more or less familiar lines; but ample use is to be made of motion pictures in association with the spread of lymphangitis, with the story of intestinal peristalsis, and other phenomena where these films have been often employed. Pictorial representations also accompany the expositions of difficult labour and cardiac movements, and other communications—such as those upon inguinal hernia and rabies, where pictorial help will be a novelty to most of the audiences. The valuable interest taken by the College in the provision at hospitals of proper accommodation and equipment is represented at the meeting by a conference on hospital standardisation.

◆

THE STOMACH IN PERNICIOUS ANÆMIA.

INTEREST in Addisonian pernicious anæmia has received an impetus during the past few years from the discovery, announced by G. R. MINOT and W. P. MURPHY in 1926, of the successful treatment of the disease by means of liver. Since then various chemical fractions of liver have been isolated, and by their critical employment in the treatment of patients much knowledge has been gained of the changes induced in the patient, and of the nature of the effective principle, which is probably a nitrogenous base. These discoveries have naturally led to further speculation about the essential nature of the disease, and several new hypotheses concerning its causation have been advanced. MEANS and RICHARDSON[1] have reviewed the new facts available, and conclude that the disease must be in some sense a deficiency rather than an infectious, toxic, or neoplastic condition. However, they conclude that it is apparently not in close relation to the already recognised deficiency diseases, since the diet of the great majority of normal individuals will not suffice to relieve the condition once developed. MEANS and RICHARDSON believe that to develop pernicious anæmia some defect of the individual is probably necessary, as well as some defect in the diet. DAVIDSON[2] has reached somewhat similar conclusions, and has considered the liver as the possible site of formation of the effective principle in normal individuals. The attractive simplicity of this idea has appealed to others, notably S. HARRIS and E. SCHWARZ, but the fact that the kidney, and apparently also the stomach, of the pig[3] has been shown to contain the effective substance, makes it difficult to prove that the principle is formed in the liver, or, indeed, in any of these organs. It has, however, been repeatedly observed in the past that the stomach contents of the patient with pernicious anæmia almost invariably show no free hydrochloric acid. It now appears that under treatment with liver the achlorhydria remains unchanged,[4] though the patient remains well as long as he continues the treatment. Hurst [5] has insisted strongly upon the significance of the gastric defect in the causation of the disease. Although much has been written about the absence of hydrochloric acid in the stomach, no particular attention has been given to the possible significance of the lack of ferments accompanying the achlorhydria. Recently, however, the possible importance of the lack of ferments in the stomach of these patients has been brought into prominence by the work of Dr. William B. Castle[6] of the Harvard Medical School. His observations on patients, carried out in collaboration with Dr. W. C. Townsend, at the Thorndike Memorial Laboratory of the Boston City Hospital, may prove an important contribution to human gastric physiology as well as to the understanding of pernicious anæmia.

---

[1] Means, J. H., and Richardson, W.: Jour. Amer. Med. Assoc., 1928, xci., 923.

[2] Davidson, S.: Edin. Med. Jour., 1928, xxxv., 322.

[3] Sturgis, C. C., and Isaacs, R.: Jour. Amer. Med. Assoc., 1929, xciii., 747; Sharp, E.: Ibid., 1929, xciii., 749.

From the facts concerning the relationship of the achylia gastrica to the disease, and in view of the circumstance that the improvement of the blood appears to bear a definitely quantitative relationship to the amount of liver consumed, a simple conception of a deficiency mechanism for the causation of the disease was evolved by Dr. Castle. He supposed that the secretory defect might be responsible for the failure of a principle necessary for preventing Addisonian anæmia. Accordingly, he decided to test the effect of substituting for the presumably defective digestion in the stomach of the patient the normal gastric activity of a healthy man. This experiment appeared to be feasible, since Minot and his co-workers had shown that the efficacy of liver extracts can be tested within a few days by estimation of the changes in the number of circulating immature red blood corpuscles (reticulocytes). From a study of some 30 cases of pernicious anæmia Castle and Townsend, using this reticulocyte reaction as a criterion, showed that feeding with 200 g. of beef muscle daily for ten days had no effect on patients with pernicious anæmia. On the other hand, if this amount of beef muscle, representing a convenient source of protein, was first eaten by a normal person, recovered by induced vomiting at the end of an hour, and thereafter given daily by stomach-tube to patients with pernicious anæmia, the same improvement in their blood occurred as is regularly produced by somewhat smaller amounts of liver. A precisely similar effect was observed on giving to the anæmic patient 200 g. of beef muscle after incubation in vitro with 300 c.cm. of human gastric juice secreted by normal men following the subcutaneous injection of histamine. The daily administration by stomach-tube of 300 c.cm. of normal human gastric juice was, however, found to be without effect. Apparently a principle capable of acting like liver or kidney was evolved from the interaction of the two individually inert substances, beef muscle and normal human gastric juice, whether combined within the lumen of the stomach or in the incubator. The presence of the beef muscle in the stomach of the patient with pernicious anæmia could apparently produce none of the effective principle; but either within the stomach of the normal man or with normal gastric juice in vitro this substance could be formed. Furthermore, it was found possible to produce the effective substance in the presence of normal gastric juice from beef muscle proteins free from fat and carbohydrate. This, however, could not be done if the gastric juice had previously been heated sufficiently to destroy its enzyme activity, or, curiously enough, if active commercial pepsin (in the presence of hydrochloric acid) instead of normal human gastric juice was used. It is clear, therefore, that hydrochloric acid alone is not responsible for the production of the effects observed.

If, then, the normal stomach can produce from beef muscle a substance effective in relieving the anæmia, it is reasonable to suppose that it could produce this substance in sufficient quantity to prevent the appearance of the disease in the normal individual. On the other hand, the defective stomach of the patient with achylia gastrica might, through a failure to produce this substance, permit the disease to develop. Such are the conclusions drawn by the experimenters, who believe their observations to suggest that the preventive process in the normal stomach is of the nature of an enzyme action upon protein in an acid medium. An obvious objection to the hypothesis is the fact that persistent achlorhydria is stated to occur in individuals who show no other features of pernicious anæmia. Many of these cases, however, can be shown to have only a temporary or an incomplete lack of hydrochloric acid, whereas the reduction of the acid of the stomach contents in the case of Addisonian pernicious anæmia is usually profound, as is also the deficiency of ferments. If Castle and Townsend's observations are substantiated a considerable simplification of the problem will have been achieved, and it will then become possible to focus attention on the causes leading to the gastric defect.

◆

CHRONIC NEPHRITIS AND LEAD POISONING.

Medical practitioners in Brisbane and other parts of Queensland have long held that chronic nephritis terminating fatally in uræmia is more prevalent in that State of the Australian Commonwealth than it is in other parts of the world. That this clinical impression has a strong basis of fact is proved by the statistical study recently published by D. Gifford Croll,[1] who shows that in the ten-year period 1917 to 1926, 1309 persons died of chronic nephritis in Queensland before the age of 40, whereas in the other three States the average number was only 425. Closer analysis of the figures from which these statistics were derived supports the belief that an unknown cause, non-existent or not operative in the other States, was responsible for this strangely high mortality. His paper is followed by a thoughtful contribution by L. J. J. Nye, who endeavours to explain the facts and by close inquiry and reasoning, which is a priori beyond criticism, reaches the conclusion that these cases of nephritis are a late result of lead poisoning in childhood.

The clinical characters of this chronic nephritis in young people appear to be a long hyperpiesis with cardiac hypertrophy and retinal changes in the late stages of the disease, albuminuric retinitis and "choked disc" being frequent. Chronic anæmia, lassitude, and gastro-intestinal disturbance are prominent. Œdema is inconspicuous, and renal failure ending in uræmia is the usual conclusion. Examining the question of streptococcal infections in the State, Nye is unable to find any evidence of undue prevalence, and whilst searching for some other possible cause, he was struck by the fact that an important proportion of cases of chronic nephritis admitted to the Brisbane General Hospital gave a past history of treatment for lead poisoning. Closer inquiry amongst the group of nephritics without such a history revealed that many of them came from wooden houses where the paint was often dry and in a powdery condition, and that as children they had been devotees of thumb-sucking, nail-biting, or a local pastime which consists in licking the rain-drops from the veranda railings. The investigator then made special inquiry into the renal function of twelve children known to have suffered from lead poisoning, and although in most of these the plumbism had occurred from six to ten years previously, he was able to show that unsuspected chronic nephritis with elevation of blood pressure was present in all of them to a sinister degree.

[1] Mod. Jour. Australia, 1929, ii., 144.

Without accepting NYE's conclusions as final until they have been confirmed in a still larger series of cases, it must be accepted that he has made out an excellent case for the consideration of public health authorities in all countries. The prevalence of wooden houses in Queensland and the tendency for paint to crumble and flake in the hot climate make lead poisoning easier than in many countries, but there is perhaps too strong a tendency in England to regard plumbism as a disease which has been practically abolished by modern regulations in the potteries and other dangerous industries. Cases of chronic nephritis in children occur sporadically, and diseases such as renal dwarfism remain unexplained. The incidence of cardiorenal disease in older people continues to a distressing degree, and NYE's investigations should stimulate inquiry as to whether lead poisoning has been as fully eliminated as is generally imagined.

◆

THE WELFARE OF THE BLIND.

THE League of Nations, in response to a request made by the British Government in 1927, has issued a report[1] on the provisions made by the various Governments of the world for the welfare of the blind. The report is based on a questionaire, replies to which were received from 20 Governments representing all the principal States of the world. A difficulty which appears at the outset of any such inquiry concerns the definition of blindness. Stone blindness, that is to say, lack of perception of light, is comparatively rare, and for practical purposes all countries include in their statistics those with some degree of vision. Many countries, including England, recognise two standards of vision, a higher one for children and a lower one for adults, the standard for children being based on educational needs, that for adults on capacity to use the eyes for work, or on a numerical standard of visual acuity supposed to correspond with this. These standards vary in different countries, and the report recognises that though useful as a guide they are quite unsuitable for rigid enforcement. No universal definition of blindness as a disability is either possible or desirable. This is a fact which of necessity makes accurate comparison between the statistics of blindness in the various countries fallacious. Taking the different categories of the blind with which the report deals, it appears that infantile blindness has been materially reduced owing to the systematic campaign conducted in most countries during the last 20 years against ophthalmia neonatorum. There are, however, still enough blind children under 5 years of age to make it desirable to have a definite policy for their care and welfare. In Switzerland efforts are directed to inform the parents of blind children how best to bring them up. Special nursery schools for these children exist in many countries, including England and Switzerland itself. These nursery or preparatory schools are nearly always in the hands of voluntary societies with or without State grants. With regard to children of school age, in many countries where compulsory education is the rule, blind children are exempted. It is only possible to provide special day schools for the blind in large cities, and apart from them schools for the blind must be residential. Among countries where compulsory education is extended to the blind their education is a subject apart, to which a great deal of attention has rightly been devoted. The leaving age in Great Britain is 16 years; in the United States and elsewhere it is higher, up to a limit of 21 years. The curriculum includes most subjects taught in ordinary schools, with the addition of Braille reading and writing. Various outdoor games are possible, including rowing, and physical culture takes a prominent place in the curriculum. Tests of intelligence are in use both in the United States and in Great Britain. It is important to make special provision for blind children who are also mentally defective. The cost of the education of the blind is borne in varying degrees by the State, public authorities, and voluntary societies. Teachers in blind schools, it is generally recognised, must be specially trained. In Austria and Great Britain they must pass a special examination. The problem of the weak-sighted, such as high myopes, is far from being solved. In Great Britain, the United States, and Canada a beginning has been made by myope or sight-saving schools or classes; for rural districts nothing has even been attempted.

Vocational training generally begins when the period of elementary education is over, but though facilities for this exist in most countries they are not as a rule compulsory. In Great Britain the Blind Persons Act of 1920 requires the local education authorities to secure adequate provision for the technical education of blind persons ordinarily resident in their area, who are capable of being benefited by such education, and the statistics for 1927 show that only 1400 out of a total registered blind population of 46,000 had failed to obtain it when suitable. Occupations in which vocational training is given include music, piano-tuning, massage, basket-, brush-, mat-, and mattress-making, chair-caning, sewing and knitting, both hand and machine, poultry farming, gardening, and domestic science. Even when trained, the blind worker remains at an economic disadvantage compared with the sighted worker. Special workshops for the blind provide for a proportion of them, a system which has been most highly developed in Great Britain. Others are organised as home workers with outside help for the provision of materials and disposal of the products. In Germany the experiment is being made of bringing the blind into ordinary factories, setting them to work among sighted workers. In 1920 a Reich law was passed requiring employers to engage a certain percentage (usually 2 per cent.) of war-disabled men, and in 1923 all blind persons, whether war-disabled or not, were included.

---

in this law. The success of this experiment is doubtful, but in a few branches of industry, such as clock-making and the production of small parts for electrical apparatus, it has been signally successful. Similar experiments have been made in England, where, of course, no compulsion exists, but there are several objections to the plan of allowing blind and sighted workers to compete with each other, even where that is possible. In ordinary industrial occupations the output of a blind worker is less than that of a competent sighted worker, by an amount variously estimated as 25 to 66 per cent., and in order that the former may earn a living wage additional payments known as "augmentation" are made to him in most countries, either from State or from voluntary funds. Numerically larger is the problem of the unemployable blind. In most countries it is dealt with by the poor-law organisation. In America the practice varies in the several States. In Great Britain, under the Blind Persons Act, the certified blind receive their old age pensions at the age of 50, and by the Local Government Act of 1929 the local authorities will have power to grant relief to poor blind persons under 50, apart from the poor-law. All these services involve a great expenditure. In England and Wales it was estimated to amount to £1,250,000 in 1924-25, of which £420,000 was contributed by voluntary societies and the balance partly by the State and partly by local authorities.

The sixtieth report of the National Institute for the Blind gives an encouraging summary of the position of the blind, so far as England is concerned. The work of the Institute is threefold: first, the organisation and allocation of charitable funds so as to avoid waste and overlapping; secondly, undertakings directly for the benefit of the blind—the publication of books and music in Braille type, the provision of homes for blind babies (the recent fire at Chorley Wood Sunshine House necessitated moving the children into Devon pending the rebuilding), the maintenance of various other schools, homes, and hostels—personal services to the blind, including the distribution of wireless sets; and thirdly, research into new openings for blind workers both in manual and non-manual occupations. Efforts are being made to increase the openings in those professions which a limited number of blind persons already practise. The Advisory Committee on the Welfare of the Blind is considering the question of promoting the further education of the adult blind by means of correspondence. Courses were organised by voluntary effort last year, and requests have been received for instruction in such subjects as English composition and literature, business correspondence, history, French, German, Latin, industrial history, and the theory of music. Such courses are likely to broaden the interest and outlook of blind persons in all phases of life and human activity. Those who are interested are asked to send in their names to the secretary of the voluntary association to which they are attached, or to their home visitor.

◆

THE RADIUM COMMISSION.

AT a meeting of the Commission on Oct. 11th it was decided to allot the four-gramme bomb of radium to the authorities of the Westminster Hospital, subject to agreement on the conditions of the loan. This bomb has been secured by the National Radium Trust for a period of three months from Nov. 1st, with an option to purchase at the end of that time. The Commission's policy of selection is based on the principle of concentration of radium at a limited number of centres in Great Britain, to which patients will be brought for treatment. At the same time it is proposed to distribute under proper safeguards supplies of radium emanation, prepared under the direction of the Commission.

Annotations.

"Ne quid nimis."

A STATIONARY POPULATION.

"WE are," says Sir George Newman in his annual report for 1928, "almost within sight of a stationary population" and the press and the public seem at last to be taking notice of a prospect of which they have been assured for the last ten years by Prof. A. L. Bowley, Prof. Raymond Pearl, and other statisticians. The population of this country was about 9 millions in 1800, 18 millions in 1850, 32 millions in 1900, 36 millions in 1910, and 40 millions now. The increase during the nineteenth century was unprecedented; from about 5 millions in 1600 the number of the people slowly grew to some 6 millions in 1700, and we have every reason to suppose that we are now returning to the almost stationary condition of the seventeenth century. Elderly and middle-aged people to-day were brought up in an atmosphere of rapid increase and universal expansion derived from their own experience of what was going on around them and from the literature of the preceding generation. What was to them the obvious fact that there were yearly more and more people, that towns were ever growing larger, that more and more public buildings were needed necessarily coloured their whole outlook on life, and their attitude towards social questions which has been passed on to those who are at present young has much the same complexion. It will need something of a mental convulsion to realise in all its implications that no further considerable increase of population is to be anticipated, feared, or hoped for, as the case may be. And it is difficult to see quite plainly what the change will involve though it is obviously of extraordinary importance.

Sanitarians will be concerned with migrations of populations rather than with changes in total numbers. No one can foretell how far the urbanisation of rural people will continue. Towns maybe will stop growing altogether and town-planning schemes will stay in the cupboard. The speculative builder will grow cautious, perhaps not till over-building has produced a useful decline in house prices and rents. Generous schemes of water-supply, sewage disposal, and other public services will suffice. Above all, sanitary authorities will have a breathing space in which they can make their equipment more nearly perfect without the immanent nightmare of unmanageable growth.

But in one important respect the stationary population of the twentieth century will be very different from that of the seventeenth. Numbers rose little between 1600 and 1700 because the death-rate was so high; they will increase only slightly between 1929 and 2000 because the birth-rate is so low. The average expectation of life at birth has enormously increased and the population of 1950 will differ from that of 1750 by containing a much larger proportion of old people. It is not our concern at the moment to discuss the effect of this on industry, production, and consumption; its medical implications are enough. Man's body in Western Europe nowadays begins to decay somewhere about 35; his elastic tissue loses its elasticity, he tends to become generally fibrous, his aorta begins to die and dilate, the glomeruli of his kidney perish a few at a time, his functional defects are obvious if he tries to run. And there is no suggestion that in increasing the average length of life anything has been done towards extending life's maximum possible duration; death at the end of the natural span is postponed, not averted, and the human body is where it has always been since vital statistics were collected. It follows that medicine and surgery will, progressively more and more, have to conduct their operations on bodies which are more or less decayed and senile. It is estimated that one-fifth of the whole population will soon be aged 55 years or over, which means that their bodies will have but an indifferent capacity of healing themselves and doing anything which involves cell growth. Medical men will spend more of their time in helping lame dogs over stiles; in its mercy civilisation is learning to put up fewer and fewer obstacles.

AYERZA'S SYNDROME.

THERE are two chief reasons or excuses for attaching a man's name to a particular disease or syndrome—one that he was the first to describe or called particular attention to it, the other that the use of a single name provides an escape from the use of a cumbersome phrase. These two reasons are often combined as they are in the case of Ayerza's disease (better called syndrome). Further, it often happens that a syndrome which appears clear-cut when first published is found to include a number of unrelated pathological conditions, and as time passes and additional similar or related cases are brought to light it becomes increasingly hard to define. At this stage, if it is to serve any useful purpose, its use should be limited to those cases which had escaped previous recognition or else to those which have distinguishing clinical or pathological features. The chief feature of the cases to which the term Ayerza's syndrome has been applied is a severe cyanosis developing secondarily to disease starting in the respiratory system. Associated with the disease of the lungs changes in the pulmonary arteries, atheroma, thrombosis, endarteritis, and hypertrophy of the right side of the heart were found.

Before Ayerza's teaching was made known by his students' publications it was recognised that many respiratory diseases, notably chronic bronchitis and emphysema, asthma, and tuberculosis might, and not infrequently did, terminate with severe cyanosis, following failure of a hypertrophied right heart and changes in the pulmonary arteries. It therefore seems unnecessary to introduce a new term for this familiar association. There remain, however, the rarer cases in which the primary lesion is in the pulmonary arteries themselves and for these a distinctive name might be advantageous. It is in drawing attention to this group of cases that Ayerza, his pupils, and subsequent writers have performed their chief service; the accounts of primary lung diseases, with secondary changes in pulmonary vessels, included in their papers have only obscured the value of their contributions. In 1920 Escudero, one of Ayerza's pupils, affirmed that there were two stages in the production of the syndrome: one bronchial, syphilitic bronchitis; and the other secondary to this, a degeneration of pulmonary arteries. This would limit the group to one in which the pathological basis consisted of syphilis of lung and either syphilitic inflammation or secondary degeneration of the pulmonary arteries. Arrillaga in 1913 had recognised the association with syphilis, but had only regarded it as playing the part of a sensitising adjuvant to chronic pulmonary disease such as chronic bronchitis and emphysema. Although it will differ markedly from the earlier conceptions and will be broader than that put forward by Escudero, it will be useful to suggest the limits of the syndrome as it is now emerging. In this sense it would be limited in its application to cases of severe cyanosis associated with diseases of the pulmonary arteries and right-sided cardiac hypertrophy in which primary lung and heart lesions can be excluded. In addition to the cyanosis, other signs of chronic venous engorgement and heart failure, such as dyspnœa, polycythæmia, œdema, and hæmoptysis, would contribute their quota to the clinical picture.

Of these primary diseases of the pulmonary artery only two kinds have been described so far, one due to primary atheroma with thrombosis, and the other syphilitic. Neither is common, and of the two so far reported the syphilitic cases have been twice as numerous as the atheromatous. It is possible that as the condition becomes better known other causes connected with such diseases as rheumatism or periarteritis nodosa may be added to them. As it is, taking the syphilitic and atheromatous together a sufficient number have been published to enable Dr. Dorothy Hare and Dr. Joan Ross to collect 23 cases to which they add another in the paper published on p. 806; whilst a further case not included in their list was contributed by Dr. Konstam to our last issue. It seems evident that cases are accumulating and are sufficiently distinctive and important to merit description and a label. Konstam evidently regards his as an example of Ayerza's syndrome; Hare and Ross, on the other hand, suggest that theirs is not. The two cases are nevertheless very similar. Each provided definite evidence of syphilis apart from the lesions in the lungs; each had a positive Wassermann reaction. The lesions in the smaller and the secondary atheroma in the larger pulmonary arteries, together with the fibrosis of the lungs and right heart hypertrophy, were so similar that although Prof. H. M. Turnbull (in Konstam's case) describes a more fibrotic and Dr. Ross a more cellular reaction they must be accepted as phases in the same process. Both cases would fit quite comfortably into the syndrome as defined above. Hare and Ross would probably, and quite legitimately, object that in the first descriptions of Ayerza's syndrome the chronic pulmonary disorders were regarded as primary and therefore we have not defined Ayerza's syndrome. As has already been explained, the chronic lesions of the lung with secondary pulmonary artery and cardiac changes are very numerous, many of them unrelated and were well known before Ayerza's teaching became public. The 23 cases collected by Hare and Ross, together with their own and that of Konstam, do form a definite group and are characterised by an equally clear clinical picture giving the necessary basis for a syndrome. Are we to call it Ayerza's when there are other authors who appear to have much stronger claims to the distinction of having it called after them? It would be easy to suggest alternative titles, but names creep insidiously into medical nosology and once established are very difficult to eradicate. Whether "Ayerza's syndrome" is so established or not it is impossible to say. In any case as first used it would be much better dropped, and if this is impossible it would, though illogical, be far better to confine its use to the only clear-cut syndrome which has emerged from the nebulous, ill-defined, and confused conceptions which first appeared.

AN ATTEMPT TO IMPROVE DOMESTIC DIET.

Mr. H. L. Mencken somewhere argues that American women provide shocking meals because they are too intelligent to bother about food. The Cattaraugus County Board of Health, on the other hand, attributes their shortcomings to ignorance, and in 1924 it appointed Miss R. M. Odell[1] as nutritionist in the hope that she would bring the findings of the laboratory and the clinician into daily life. An investigation into the food habits of the people was started by the study of school medical records and by a questionaire of representative homes. The latter inquiry was undertaken through the local groups of home bureau women (corresponding to our women's institutes) so as to obviate the natural resentment of the families to apparently impertinent questions from an outsider. Groups were selected from (1) professional workers, (2) town labourers, and (3) farmers, and their food intake was analysed for a week. Various groups were thus examined over a period of 12 months so as to avoid seasonal considerations, and it was found that in the rural districts there was a lack of green vegetables in the diet. The people were therefore stimulated into planting gardens, and home. This at present can only be a voluntary effort, for private dwelling houses are expressly exempted by all Acts so far passed by Parliament. In the 1926 Act permission is given to local authorities to unite with adjoining authorities to form statutory bodies for carrying out the provisions of the Act. Several such bodies have been formed. Two years ago, at the instigation of the Coal Smoke Abatement Society, 90 of the local authorities in and about London held a conference at the Guildhall which was addressed by Mr. Neville Chamberlain, the Minister of Health then in office. The conference appointed a committee to draw up recommendations to secure uniformity of administration of the Smoke Abatement Acts, and this committee on Oct. 15th brought its recommendations to the conference. Some of these recommendations were presented to the conference held in Buxton this month and have become an accepted part of the policy of the newly formed National Smoke Abatement Society.

GAS GANGRENE IN THE AMERICAN ARMY.

THERE were 2718 cases of gas gangrene, 1267 of them being fatal, among the 224,080 American soldiers wounded during the war on the Western front. This incidence of roughly one case of gas gangrene per cent. of the wounded, with a mortality-rate up to 50 per cent. of the cases, is consistent with the records of the British, French, and German medical services. The Americans on taking the field had the advantage of the considerable research already done by the other belligerents on the prevention of anaerobic infection. To counterbalance this, however, they found themselves for the most part fighting in a terrain which had been richly manured for centuries, and was thickly strewn with human and animal organic matter as a result of several years of intense stationary warfare. In Volume XII. of the archives of the Medical Department of the United States Army in the World War[1] a fully illustrated account of gas gangrene, as it affected the American army, is set out. It is interesting to compare the account of its pathology with that given in the first volume of the System of Bacteriology recently published by the Medical Research Council, which is also based largely on the experience gained during the war of this infection. In the American work gas gangrene is considered under two headings. First the virulent forms are described and subdivided into emphysematous, toxic-œdematous, mixed and putrefactive types. The illustrations provide a comprehensive atlas of the pathology and histology of these states. Secondly, an avirulent form is recognised and described, in which the infection tends to resemble in time a bronze-like erysipelas and has a good prognosis. The bacteriological descriptions are mostly concerned with the four anaerobes *B. welchii*, *Vibrion septique*, *B. œdematiens*, and *B. histolyticus*. *B. welchii* naturally receives most consideration. It is stated to be not a true parasite, but a saprophyte incapable of growth in healthy tissue, and able to thrive only if the body cells are first injured by some mechanical or chemical means. Its lesions are said to involve the muscles, the blood-vessels, and the subcutaneous connective tissues. On this point American views differ from those held in Great Britain, where the site of the local lesion is not regarded as of supreme importance. In a Medical Research Council report published in 1919[2] it is suggested, as the outcome of experimental infections, that the localisation of the infection in muscle is purely an accidental phenomenon; since the organism does not grow more readily in muscle than elsewhere. On the other hand, the importance of septicæmia with visceral dissemination is emphasised. Two small matters emerging from the American survey are at least of retrospective interest. The first concerns "laudable pus" which military surgeons in former times greeted with enthusiasm as of good prognostic significance; it is recorded that pyogenic organisms, with certain exceptions, though they might not alter the general outlook for the patient, yet tended to inhibit the growth of the gas gangrene organisms. The second concerns scabies. It was noticed that the burrow of the female provided an ideal and much-frequented culture tube for the anaerobes.

THE annual dinner of the Royal Society of Medicine will be held at the May Fair Hotel, Berkeley-square, London, W., on Thursday, Nov. 21st, at 7.30 for 8 P.M. The Prime Minister, the Minister of Health, and the French Ambassador have consented to be the Society's guests of honour.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XLVIII.

THE DIAGNOSIS OF GONORRHŒAL INFECTIONS IN THE MALE.

THE bacteriologist can give considerable help in the diagnosis of gonococcal infections in spite of the elusive tendencies of the gonococcus. It is proposed here to deal solely with microscopical and serological tests in the male.

Collection of Specimens.

The more important points in the collection of specimens deserve attention. First, in order to make sure that the pus is coming from the meatus and that the condition is not one simply of balanitis, all pus surrounding the meatus and preputial sac should be wiped away. Then the patient should be instructed to squeeze up the pus from the base of the urethra. The pus is collected on one or preferably two swabs (one for films and the other for cultures). If more than a few minutes is likely to elapse before the swabs reach the bacteriologist it is advisable to make a couple of films from one of the swabs straight away. If delay is unavoidable, it is important to see that the tubes into which the swabs are placed are properly corked to prevent drying up. A thinnish film of even consistency is to be aimed at, and some prefer to use a platinum loop for this procedure.

When cultures are desired it is preferable for the patient to attend the laboratory, for the material must be inoculated and incubated immediately. The gonococcus very soon dies out at room temperature. Cultures should always be made in medico-legal cases. Ordinary agar is useless for this purpose, and the best medium is hydrocele fluid agar.

Examination of the centrifuged deposit of urine is valuable in the later stages when the discharge has disappeared. The urine should be held for at least four hours and then passed direct into one or more sterile wide-mouthed bottles, care being taken: (*a*) thoroughly to cleanse the meatus with spirit and allow it to dry off; (*b*) to cork the bottle immediately it is full; (*c*) to send the specimen to the laboratory for immediate examination. If the material is not examined at once contaminating organisms will probably multiply and obscure the result. Furthermore, pus cells if few in number are apt to disintegrate and become unrecognisable.

[2] on Anaerobic Bacteria and
Jour., I uncil, Special Report Series
Res 919.

In collecting a specimen following prostatic massage the patient is instructed to retain his urine for three or four hours and the meatus is then cleansed with spirit. After this the prostate should be massaged and any secretion coming away from the meatus can be collected direct on to a slide, which is put aside to dry in the air. The patient then empties his bladder into two or three wide-mouthed sterile bottles. This washes out the secretions and any pus that may be present, and these are eventually recovered in the laboratory by means of the centrifuge.

It must be emphasised that the gonococcus in vitro is a delicate organism. For this reason specimens of urine and prostatic fluid sent to the laboratory for examination should be as fresh as possible. In the later stages of the disease when the gonococcus becomes more and more difficult to find, it is liable to appear only intermittently in the discharges and in urine. To overcome this difficulty provocative measures may be employed. A discharge may be deliberately provoked by irritation of the urethra. The following methods have been adopted for achieving this: the passage of an instrument; the instillation of silver nitrate into the posterior urethra; the use of a provocative injection of gonococcal vaccine, and hard physical exercise and alcohol.

Bacterial and Cellular Elements.

In the interpretation of reports on material sent at various stages of the disease it must be remembered that during the first few hours of the infection gonococci may be scanty in the discharge, but very soon they appear in large numbers and can be identified with considerable ease. It is not long, however, before secondary infection takes place, and it is a rule for one or more of the following organisms to appear with the gonococcus: staphylococcus (usually albus), diphtheroid bacilli, enterococcus, *B. coli*. These organisms are probably mildly pathogenic and help to keep up the infective process, for they are found in chronic cases when the presence of the gonococcus can no longer be established. *B. coli* is not so common as the rest, but when it does occur it may prove very resistant to treatment. The distinction between a secondary and a primary *B. coli* infection can only be made by a study of the history in those cases where gonococci have not been found in the early stages.

Apart from bacteria in the pus, information of importance can be obtained from the cellular content. In the early days of an attack 90 per cent. or more of the cells are polymorphonuclears, the remaining 10 per cent. or so consisting chiefly of desquamated epithelial cells. This proportion lasts for a considerable time, and it is only when the infection is approaching its termination that the percentage of epithelial cells rises and the polymorphonuclears disappear.

While there are still polymorphonuclears to be found in the centrifuged deposit of urine, treatment should be continued. It is by no means uncommon to receive a specimen of urine or a smear from an old chronic case, and the only information demanded is "? presence of gonococci." Cases of this sort make one suspect that too much importance is apt to be placed by some practitioners on the presence or absence of gonococci and not sufficient attention on the presence of pus cells and secondary organisms. It does not seem unreasonable to aim at getting the centrifuged deposit of urine entirely free from pus cells as well as from gonococci and secondary organisms after prostatic massage and the various provocative methods have been applied, but this standard of cure is admittedly a high one.

The Complement-fixation Test.

Within certain limits this test has value in the diagnosis of gonorrhœal infections, though its value and reliability cannot be compared to the Wassermann reaction in the diagnosis of syphilis. The test depends on the detection in the blood of a complement fixing antibody, and the chief limitation of the test with the technique at present employed is the low concentration of the antibody in the serum. Owing to this some cases of undoubted gonorrhœa give a negative test throughout. However, it is possible that in the future, with improved technique, this disadvantage may be overcome.

The importance of the test at present lies in its specificity. Of 100 specimens of bloods from people who gave no history of gonorrhœal infection which were tested in this laboratory a few years ago, only two gave anything approaching a positive result. These exceptions occurred in patients attending the V.D. clinic for syphilis, and so there is just a possibility that the histories given to us by the patient were not correct. A positive result, especially if it is supported by a possible history or clinical symptoms, can be taken as very strong evidence in favour of a gonococcal infection. The reaction does not usually become positive until the disease is approaching the chronic stage, and a positive result can only be expected in somewhere between 50 and 80 per cent. of cases. The highest percentage of positive reactions is to be found in cases with complications such as pyosalpinx, arthritis, iritis, and the chief value of the test lies in the diagnosis of the nature of these conditions. About 2 c.cm. of blood are required for the test, preferably obtained from a vein, owing to the importance of keeping it sterile. The test cannot be performed in blood contaminated with bacteria. It is important to note that the test has no value in cases which have received vaccine treatment.

Tests of Cure.

In some cases it is exceedingly difficult to decide whether a patient who has been suffering from a chronic gonococcal infection is cured or not. Before a decision is arrived at the patient should be tested on at least three different occasions, and only if negative results have been consistently obtained should he be considered free from infection. It is unwise ever to accept one negative report as conclusive evidence of cure, and two out of the three tests should have been made *after* the use of a provocative measure. The ideal aimed at in treatment is the complete disappearance of not only gonococci but also of pus cells from the secretions. Unfortunately, this ideal cannot always be achieved. Even after prolonged treatment the prostatic fluid and urine may still contain a certain amount of pus, and the question arises as to whether such a patient should still continue under treatment. Some authorities are willing to overlook the presence of a few pus cells in these cases and discharge the patient, whereas others are not prepared to go so far. The question is undoubtedly one of considerable difficulty, since the fear must always exist at the back of the practitioner's mind that gonococci are still present, although undiscovered by the pathologist. Certainly in some of these cases the inflammatory process is kept up partly owing to the irritation of the antiseptics employed and the condition may clear up on the cessation of treatment.

The complement-fixation test has proved to be of little value as a test of cure in gonorrhœa, and is seldom employed at the present day for this purpose. Various continental authorities have recommended the use of spermo culture, and have reported that it has frequently yielded positive results when other attempts to find gonococcus have been negative, but the majority of patients will object to the carrying out of this test, and it is seldom used in England.

A. B. ROSHER, M.R.C.S., D.P.H. Lond.,
Director of the Charing Cross Hospital Institute of Pathology.

THE WEIR HOSPITAL.—The report of this Balham hospital for 1928 shows that there were 933 in-patients and 10,627 out-patients, the figures including 10,106 casualties. The X ray department is to be enlarged as soon as means permit.

Special Articles.

THE RELATIONSHIP OF CORONER AND MEDICAL PROFESSION.

A Lecture delivered to Post-graduates, at the Manchester Royal Infirmary on Oct. 11th, 1929,

BY C. W. W. SURRIDGE,
H.M. CORONER FOR THE CITY OF MANCHESTER.

I SHOULD like at the outset to point out that the coroner is an independent official. He is not a police official, and within certain limitations he has a wide discretion and a heavy responsibility. He is not bound by the laws of evidence, although in criminal matters, in my opinion, he should strictly observe them. The practice and procedure varies amongst different coroners, and I am only speaking of my own practice and procedure.

A coroner can only act upon information. In all cases where a crime is concerned, or serious accident, he usually gets his information immediately from the police, but in a very large number of cases the police are not called in, and it is from the doctors that the coroner derives his information, or from the registrar, whose duty it is to scrutinise closely the doctor's certificates, and to refer them to the coroner if he is unable to accept them.

Obligation to Inform.

There is no statutory obligation upon a doctor to inform the coroner, though it is said to be his common law duty, as one of those about the deceased, to inform the coroner or his officer, or the police, where he has any reason to suppose an inquest may be necessary.

But although there is no statutory duty upon a doctor to inform the coroner, it is, in this city at any rate, an unwritten law of courtesy for the doctor to inform the coroner at the earliest possible moment of any case of his which calls for the coroner's intervention. If he disregards this courteous procedure, he not only ruffles the coroner, who is a very autocratic individual and capable of being extremely unpleasant on the telephone, but what is of more immediate concern to the doctor, he runs the risk of alienating the regard and possibly the future patronage of the family of the deceased. If the doctor contents himself with posting his certificate to the registrar, who, upon receipt of it, posts the appropriate form to the coroner, it is three days after the death before the coroner knows anything at all about it. It is very inconvenient and unpleasant for the relatives to be informed, perhaps on the eve of the funeral, that an inquest must be held.

The majority of doctors in this city fully realise the position, and are anxious to work in harmony with the coroner, but difficulties do arise through a doubt as to the circumstances under which a doctor should communicate with the coroner. This question is answered by reference to Section 3 (1) of the Coroners' Act, 1887, which enacts: "Where . . . . . there is reasonable cause to suspect that such person has died either a violent or unnatural death, or has died a sudden death of which the cause is unknown, or that such person has died in prison . . . . . the coroner shall . . . ." in effect hold an inquest.

Violent or unnatural deaths include all cases where death is due to an accident of any kind—however trivial the original accident may have been. They also include deaths from all forms of poisoning, including not only acids and alkalis, but alcoholic or food poisoning, or death from industrial disease, or deaths from suicide.

Deaths under Anæsthetics.

To this cause of death I should like to call your special attention, because I believe that the practice which I adopt is not universal. For my part, I cannot see how such deaths under anæsthetics can come under the category of deaths from natural causes, and I therefore always hold inquests in such cases. In most cases it is true that the inquest is a pure formality, and I sympathise very sincerely with doctors who have to attend an inquest in cases where they have been called upon to give an anæsthetic to a patient where the chances of his surviving the operation were very remote, but I can assure them that in such cases not the slightest reflection is cast upon their skill.

I am convinced that the holding of an inquest is a great public safeguard, and that it is a good thing to satisfy people that everything has been properly carried out, and that all proper precautions have been taken, and that all known means of resuscitation were at hand and employed. In some cases—fortunately very few—I have found that my Inquiry has been fully justified, and it is only on such occasions that I have any adverse comment to make.

With regard to cases of accidents, I find that sometimes a doctor fails to report a death from a simple accident, and the excuse given for his omission is that he did not report it as no question of compensation was involved. Of course, that is an entirely erroneous impression. The coroner has to hold an inquest in every case where death has been caused or accelerated by an accident, quite apart from any question of compensation. Another mistaken impression is that it is not necessary to inform the coroner where death has occurred more than a year and a day after the accident. This impression springs from the fact that no person who has inflicted the injury can be convicted of murder or manslaughter if death ensues after the lapse of a year and a day from the injury, but the coroner is solely concerned with the question as to whether the injury has or has not caused or accelerated death.

Compensation Cases.

Cases where compensation may be involved demand especial care. I very frequently get cases where the doctor gives a certificate of death from some natural cause, but where the relatives mention to the registrar or to me that the deceased had an accident at his work some months ago, or has been working amongst lead or chemical fumes, and the question is raised whether the accident or the work upon which the deceased has been engaged has attributed to his death. In such cases I always hold an inquest if desired to do so by the relatives and order a post-mortem examination. This does not mean that I distrust the diagnosis of the doctor, but the matter has to be fully investigated. If I were to refuse to hold an inquest and the case went for compensation, the county court judge might want to know why no inquest had been held. Very often the doctor has never been informed of the accident or condition of work, and he should always make careful inquiries on these points, and where he has reason to believe that the relatives consider that the accident has contributed to the death, he should always report it to the coroner.

Cases of sudden death do not necessarily demand an inquest. Where the doctor has attended a patient for heart disease, for example, and death occurs suddenly, a doctor is quite in order in giving a certificate if he is satisfied that no other cause, such as accident or poison, has contributed to the death, but under the regulations contained in the last Registration Act, 1927, the registrar has to refer to the coroner all cases where the deceased has not been seen by the doctor after death, or within 14 days of death, and in such cases it is a great convenience to all concerned if the doctor notifies the coroner at once. But informing the coroner does not relieve the doctor from his duty of issuing a certificate where the cause of death is diagnosed.

The Question of Fees.

The only payment authorised by statute is a fee for giving evidence at an inquest, or for making a post-mortem examination. No payment is made by me for any letter written to me by a doctor or any other communications. I want to emphasise the fact that I do not order a doctor to make a written report. The letters to which I allude are purely voluntary communications. In cases where I have to ask for information on the telephone, I am invariably assisted with the very greatest courtesy by the doctors in this city. If a doctor is in any doubt whatever about a case he should consult the coroner, for I am only too ready to assist them as they assist me. Content yourselves with stating the facts, and leave the responsibility to the coroner. Never try to evade an inquest. I have two golden rules. In all cases where the relatives desire an inquest I always hold one, and whenever any undue pressure is brought to bear upon me not to hold an inquest I always hold one. This practice I have found to be fully justified on many occasions.

It has never been my practice to call doctors unnecessarily—e.g., in simple cases of fall down stairs or burns, where I get evidence of the injuries from other sources, but in cases where compensation is involved I generally call the doctor, as the employers or insurance companies may desire to cross-examine the doctor through their counsel.

Evidence in Court.

On the question of giving evidence in court, perhaps I may be permitted to give you some hints.

(1) Always speak up, so that everyone may hear you. Do not act as if you were carrying on a private conversation with the coroner; remember that relatives have a right to hear what you say and an interest in your evidence.

(2) Make your language as simple and as untechnical as possible.

(3) Be as concise as you can, but at the same time be luminous.

(4) Formulate your opinion and conclusions with care, and do not allow yourself to be shaken by cross-examination. I do not mean by this that you can always be exact. Medicine is not an exact science, —e.g., you may say death was undoubtedly, in my opinion, caused or accelerated by the accident, or, in my opinion, the accident had no connexion with the cause of death, or you may say I am unable to say definitely whether death was caused or accelerated by the accident or not. But once you have made up your mind, hold your ground, and do not allow yourself to be shaken by cross-examination.

(5) Do not show any resentment at being cross-examined. Remember, it may be counsel's duty to try to weaken or negative your evidence. Content yourself with reiterating your conclusions or adding reasons for those conclusions.

THE PRACTITIONER'S EMPLOYEES.

THEIR POSITION UNDER NATIONAL INSURANCE.

MEDICAL and dental practitioners are often in doubt about the position of their employees under the various Acts which regulate national health insurance, contributory pensions, and unemployment insurance. An explanatory memorandum (317/X) has therefore been issued by the Ministry of Health and other departments concerned. The main facts may be summarised as follows:—

Health and Pensions Insurance.

Under the National Health Insurance Acts and the Widows', Orphans', and Old Age Contributory Pensions Act contributions have in general to be paid for everyone over 16 who is earning not more than £250 a year for whole-time service, and also for everyone whose employment is by way of manual labour. Thus, *subject to what is said below*, health and pensions contributions are payable f dispensers, secretaries and reception c mechanics and apprentices, domestic servants, hall-porters, and chauffeurs.

The contributions for such persons must be paid for each week during which they are employed; and in any week when they have been employed in an insurable capacity by more than one employer, the first employer is responsible. These requirements are explained in detail in Pamphlet A, which may be had from the Health Insurance Departments of the Ministry of Health, Whitehall, S.W. 1.

Rate of Remuneration.—In arriving at the rate of remuneration of employees (other than manual workers) account should be taken of the value *to the employee* of any emoluments in kind, such as board or lodging, provided at the employer's expense. The cost to the employer, though often a useful guide, is not necessarily to be taken as the value of remuneration in kind. "The employer and the employed person," says the memorandum, "will usually be in a position to agree as to what should be taken as a fair money equivalent of the value of such emoluments to the employed person, and it is only in cases of special difficulty that reference need be made to the Insurance Department. Ordinarily, the value of board and lodging is assessed at about 35*s.* a week. In the case of part-time employment the equivalent remuneration for normal whole-time employment should be taken."

Manual Labour.—The question whether an employment is or is not by way of manual labour is only material where the pay exceeds £250 a year, as persons who receive less are insurable in any event. The question arises principally in the case of dental mechanics and chauffeurs.

A dental mechanic is employed by way of manual labour, notwithstanding that he supervises assistants in addition to engaging in the manipulative work involved in making dentures, plates, artificial teeth, crowns, &c. A decision of the Minister of Health to this effect has been upheld by Mr. Justice Roche in the High Court. On the other hand, a dentist's assistant who is engaged in the ordinary duties of a qualified dentist and who attends to patients in that capacity is regarded as employed otherwise than by way of manual labour. But where such an assistant also takes part in mechanical work, regard must be had to the main and substantial nature of his duties. If he is substantially employed as a dental mechanic he is a manual worker. In case of doubt reference should be made to the Insurance Department for a ruling.

A chauffeur who is required to clean the car and to effect running repairs, besides driving, is normally regarded as employed by way of manual labour, and is, therefore, *compulsorily insurable irrespective of* his remuneration.

*Unemployment Insurance.**

From the practitioner's point of view there are three main classes in which liability to unemployment insurance does not coincide with liability to insurance under the Health Insurance and Pensions Acts—viz., employment as a female professional nurse for the sick, employment in domestic service, and employment in agriculture (including horticulture).

Female nurses have been excepted from unemployment insurance since July, 1922. The exception does not, however, extend to dispensers, secretaries, or persons employed by doctors or dentists on such duties as to receive patients, make appointments, answer telephone messages, clean and sterilise instruments, clean and dust surgery fittings, mix cement, hand instruments, &c., to the dentist, or attend on anæsthetic cases, unless the attendant is a duly qualified nurse and employed as such.

Employment in domestic service is excepted from liability to insurance only where the employed person is not employed in a trade or business carried on for the purposes of gain. It has been held by Mr. Justice Roche in the High Court that a doctor is carrying on a business for the purpose of gain within the meaning of the Acts, and domestic servants employed in that business are therefore required to be insured. The judge decided that a chauffeur employed primarily to drive a doctor on his rounds, and a domestic servant employed by a doctor in a nursing home carried on by him in addition to his practice, were employed in the business of their respective employers. These decisions are held to cover in principle chauffeurs employed to drive or accompany doctors on their rounds, servants employed to attend upon the patients or staff in a nursing home, and servants employed at the surgeries of doctors or dentists to admit patients, make appointments, or otherwise in connexion with the employer's professional requirements.

---

* The requirements of the Unemployment Insurance Acts are set out in detail in *Leaflet U.I.L.4*, *which may be had from the* Ministry of Labour or from any Employment Exchange or Branch Employment Office.

Servants employed in doctors' or dentists' private residences solely in connexion with their employers' personal needs, and servants whose duties in connexion with their employers' business are confined to cleaning the surgery and admitting occasional patients, are not regarded as employed in the business and are not, therefore, required to be insured against unemployment. Servants employed by doctors or dentists in connexion partly with their employers' professional requirements and partly with the employers' personal needs should be regarded as insurable if their substantial employment is employment in the former capacity. It has been held by Mr. Justice Roche in the High Court that one-third is a substantial part of an employee's working hours.

Employment in agriculture—e.g., as a gardener, whether regular or jobbing—is totally excepted from unemployment insurance.

The Services.

ROYAL NAVAL MEDICAL SERVICES.

THE following appointments have been made: Surg. Lt.-comdr. G. S. Rutherford to *Calypso* and Surg. Lt. A. M. Lawrence-Smith to *Hermes*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. St. G. B. D. Gray to be Surg. Lt.-Comdr.
Proby. Surg. Lt. R. H. Enoch to be Surg. Lt.
Proby. Surg. Sub-Lt. K. E. L. Yuill to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. D. S. Buist, half-pay list, late R.A.M.C., retires on retd. pay on account of ill-health.

Capt. R. R. Evans to be Maj. (prov.).

TERRITORIAL ARMY.

W. G. Platt to be Lt.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. W. Parsons resigns his commission on appointment to a commission in the Royal Army Medical Corps.

INDIAN MEDICAL SERVICE.

Capt. (prov.) F. W. H. Caughey relinquishes his proby. appointment.

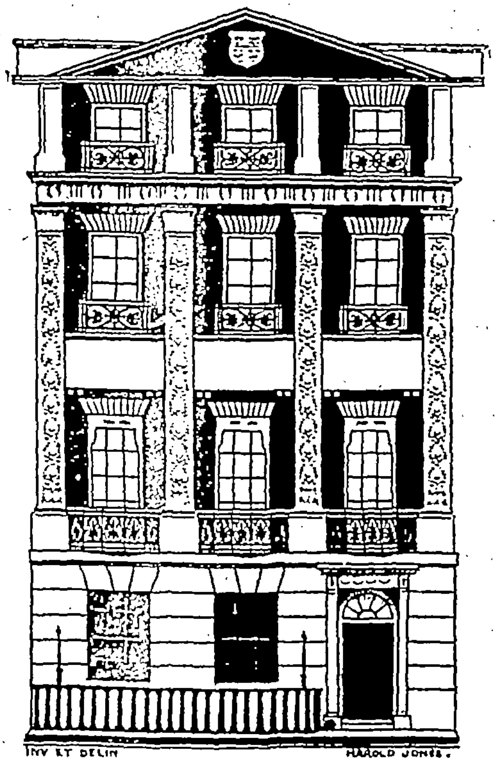
The undermentioned have vacated their appointments in India:—A.D.M.S.: Col. W. O'S. Murphy, I.M.S., A.D.M.S. (temp.): Maj. (Bt. Lt.-Col.) R. A. Bryden, R.A.M.C.

ELSIE INGLIS HOSPITAL, BELGRADE.—On Thursday last week Anne, Viscountess Cowdray, opened the hospital which has been erected in Belgrade in memory of Dr. Elsie Inglis, who went to Serbia during the war as Commissioner for the Scottish Women's Hospitals.

A CENTRAL ANÆSTHETISING PLANT AT ST. BARTHOLOMEW'S.—The basement of the new surgical block now being erected at St. Bartholomew's Hospital will be fitted with a central anæsthetising plant. Pipes from cylinders of hardened steel will carry oxygen and nitrous oxide to the various theatres where taps and a mixing chamber will facilitate the adjustment of the components. More than 20,000 gallons of gas are used in the hospital every week.

THE NEW HOME OF The Lancet.

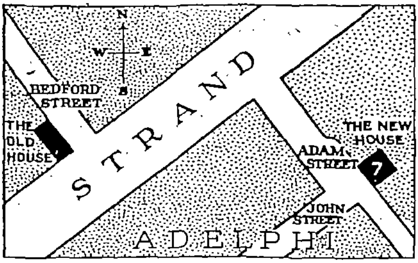
IN the course of the next few days THE LANCET Offices will be transferred from 1, Bedford-street, and the adjoining house in the Strand, where our home has been for the past 80 years, and more, to 7, Adam-street, Adelphi, London, W.C., premises only 100 yards from the old address.



NO. 7, ADAM-STREET, ADELPHI.

During the past 105 years the editorial office of THE LANCET has been in, or within a few yards of, the Strand, and in the immediate vicinity of the new address. Originally the paper was edited from a house in Norfolk-street, Strand—a very different street in appearance from the present Norfolk-street. Here Thomas Wakley, the Founder of the paper, was engaged in private practice; here he was discovered by Sir Astley Cooper abstracting (Cooper called it "pirating") the great man's lectures, which were in course of delivery before the United Medical Schools of Guy's Hospital and the then adjacent St. Thomas's Hospital. The business of the first printer of the paper, G. L. Hutchinson, was carried on within a few paces, in the Strand. During the first 25 years of our existence the editorial work was done largely in Wakley's private house, but the printing office was changed several times, there being, as a matter of fact, no particular anxiety on the part of any firm to be even partly responsible for the issue of a newspaper whose activities were being so often, and so expensively, discussed in the law courts. But in Bolt-court, Fleet-street, Wakley at last found printers who for ten years acted as publishers, the firm being that of Mills, Jowett and Mills, of whom Jowett was the father of the famous Master of Balliol. In 1836 Wakley decided to become—probably was forced to become—personally responsible for publishing, as well as editing, his paper, and this he did from an address in Essex-street, Strand. But six years later the firm of Churchill came upon the scene, providentially it appears, for Wakley was a reckless man of business, as well as much absorbed in Parliamentary affairs. A situation of pecuniary uneasiness was thus relieved, and five years later Wakley resolved to be again his own publisher. In 1847 the lease of the building at the corner of Bedford-street and the Strand, now being evacuated, was acquired, and in this building during the 82 years of tenure THE LANCET has been published. Until early in 1921 the paper was printed at these offices, as well as edited and published, and during that period considerable additions to the house were made, as well as many internal transformations carried out. But in 1920 the interests of Wakley and Son, Ltd., having passed into the hands of Messrs. Hodder and Stoughton, the composing rooms were done away with, and since 1921 Messrs. Hazell, Watson and Viney, Ltd., have been responsible for the printing.

The proprietors of THE LANCET have now purchased as a freehold 7, Adam-street, Adelphi, and the work of editing and publishing will be transferred there in the course of the next fortnight. The accompanying illustrations show the façade of our new home, and its situation in the famous quadrangle of symmetrical streets, erected on arches. This beautiful piece of building was designed and executed by John, Robert, James, and William Adam, on the site mainly of old Durham House, which had become a more or less derelict district of mud and slime, used only for the mooring of coal barges for the supply of a London and a Westminster which had then no existence beyond Hyde Park Corner. The streets in the Adelphi were named after the Christian names of the four brothers, though William-street has since been changed to Durham House-street. But to the bounding street on the east was given the name of Adam-street, while the beautiful pile facing the Thames received the name of Adelphi-terrace. It may require imagination to see the influence of Diocletian's famous palace at Spalato upon the architecture of the Adelphi, but Robert Adam, the most celebrated of the four brothers, made a careful study of that magnificent ruin, and has himself recorded that he did this designedly, when determining to apply classical models to modern dwellings; because the Emperor's huge villa—it now constitutes the skeleton of nearly all the town of Split—was built as a residence, and was not a public institution such as usually formed a model for imitation or a source of suggestion. The whole enterprise of constructing the Adelphi was attended with difficulty. The elegant streets had to be constructed on arches for the securing of a foundation and of provision for wharfage on the Thames below, while obtaining a level access from the Strand. The expense incurred was huge, and was swollen by the legal opposition to the scheme from the Corporation of London, which body put forward proprietary claims to the foreshore. However, one private Bill in Parliament disposed of this matter, while another private Bill sanctioned the institution of a lottery for raising further funds, and finally the work was completed.



No. 7 Adam-street is the central feature of a line of houses in the eastern street, and faces down John-street. It was, 100 years ago, the town house of Mr. Christopher Smith, then Member of Parliament for St. Albans. It became, 20 years later, the home of the Evangelical Alliance, which was inaugurated in Liverpool in 1845. Sir Culling Eardley, one-time Member of Parliament for Pontefract, and the founder of the Evangelical Alliance, resided at 7, Adam-street in 1858. Under his direction the early activities of this body, designed to constitute a working union between Protestant peoples, while forwarding the cause of religious liberty, were fruitful. For the Alliance secured recognition of the Christian faith from the Sultan of Turkey and the Khedive of Egypt, the repeal of penal laws in Sweden against Roman Catholicism, and elsewhere liberal reforms in favour of Jews. Later the religious atmosphere of the house became very pronounced, for its walls sheltered, in addition to the Evangelical Alliance, missionary, educational, and charitable associations. For the next 25 years this character was retained, but our immediate predecessors in the house were, appropriately enough, considering the character of the structure, a firm of architects. The reconstruction was carried out under the direction of Mr. Graham R. Dawbarn, A.R.I.B.A.

An informal At Home was held on Wednesday evening, Oct. 16th, on the new premises.

MEDICINE AND THE LAW.

Doctors Fined under the Dangerous Drugs Acts.

THE maximum penalty for failing to comply with Regulation 2 of the Dangerous Drugs Consolidated Regulations in the matter of keeping a register and making the prescribed entries therein is 12 months' imprisonment, or a fine of £250, or both. Fines considerably smaller than the maximum have hitherto been inflicted, but magistrates are disposed to warn defendants that the offence will be seriously regarded in future. Earlier in the month two London doctors were ordered to pay fines of £20 and £10 respectively at Marlborough-street police-court, with 10 guineas costs in each case. It appeared that the police had been pursuing inquiries into a case where it was suspected that a man and woman were obtaining drugs otherwise than for their personal use, and were trafficking in them in an improper manner. A detective-inspector visited a number of chemists, and found prescriptions signed by the two doctors, against whom proceedings were taken. One of the two doctors, who had omitted to enter a certain quantity of heroin, attended at Scotland Yard and was shown certain prescriptions. He admitted that these were signed by himself, and that the contents of four of them were in the handwriting of the patients. He also admitted that ten orders for drugs obtained for professional use, though signed by himself, were in the handwriting of the man whose dealings the police were investigating as already stated, and that although the orders were marked "for professional purposes," the drugs were obtained for, and were sent direct to, this man. He further admitted that he had kept no official register; he produced a list of drugs given to the man and woman, but it was stated on behalf of the Director of Public Prosecutions that the list in no way complied with the Regulations. In this case the doctor, who pleaded that he was an anæsthetist, not in the habit of prescribing dangerous drugs and entirely ignorant of the Regulations, was fined £10. In the other case there were similar features, prescriptions having been signed by the medical practitioner and filled in by the patient, and no proper register having been kept. The doctor produced a memorandum pad containing entries in pencil, but in this case, again, the prosecution contended that the document failed to comply with the Regulations, there being in particular no record of purchases. The defendant pleaded forgetfulness, due to overwork and ill-health, and added that the Act was difficult to interpret. The magistrate imposed a heavier fine in this case, on the ground that this defendant was aware of the need of keeping a register.

Members of the medical profession naturally find the meticulous compliance with the Dangerous Drugs Regulations a troublesome duty which, in moments of pressure, they may be inclined to postpone. The increased vigilance of the police in these matters brings irregularities to light sooner or later. It is not that the police invade the consulting-room at random in order to see if the Regulations are obeyed; it is rather that the police, in following up some allegation of improper traffic in drugs on the part of laymen, are obliged to trace the documents back to the source.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

ANNUAL CONFERENCE IN NEWCASTLE-UPON-TYNE, OCT. 10TH–12TH, 1929.

THE fifteenth annual conference of this Association was opened on Oct. 10th by the Lord Mayor (Councillor A. W. LAMBERT, M.C.), who welcomed the delegates on behalf of the city of Newcastle. Over 350 delegates attended including more than 200 members of the medical profession. We report the four chief sessions.

A Sociological Survey.

Under the chairmanship of Sir ROBERT PHILIP (Vice-Chairman of the Council) the first paper was read by Mr. HENRY A. MESS, Ph.D. (Director of the Tyneside Council of Social Research), entitled Tuberculosis on Tyneside. Dr. Mess said that a survey of social conditions in 13 industrial towns on Tyneside had been undertaken during the years 1925–28, and it had been found that with the exception of two middle-class "dormitories," all the towns had death-rates from pulmonary tuberculosis for the quinquennium 1921–25 considerably in excess of the national death-rate; in respect of non-pulmonary tuberculosis the figures were even worse. Overcrowding existed in the houses of Northumberland and Durham to an extent unparalleled in England and Wales, and this coincided, except in the mining districts, with the excessive death-rate from tuberculosis. The overcrowding was not only within the homes; in addition there was overcrowding of houses on the land resulting in an unusually large outpouring of domestic smoke, with depletion of sunlight together with the impossibility of effective isolation of diseased individuals. The local industries, shipbuilding and ship repairing, were very subject to violent fluctuations—livelihood was therefore uncertain and often scanty, leading to worry and malnutrition, which predispose to the disease.

Discussion was opened by Councillor JOHN BARKER (Chairman of the Tuberculosis Committee, Newcastle-upon-Tyne) who dealt with the local situation and the facilities provided for handling the problem, and made special reference to Newcastle's position. He warned local authorities against building types of low-rented houses which would in 20 years' time present another slum problem, suggested that the National Association should press the Ministry of H[illegible]lth for stricter obligation on local authorities to BARTH[illegible] now being adequate tuberculosis dispensaries, educa- fitted with a[illegible]es, and institutional segregation, and [illegible]ders of hard[illegible]he setting up of regional advisory [illegible] the vario. KERR (M.O.H., Newcastle) paid a will facilita[illegible]'s work locally, and said that it 20,000 gall[illegible]rculosis conscience of Tyneside. [illegible]x (M.O.H., Manchester) stated

provide tional agenci recommended c[illegible]cils.—

that while there must be earlier and more complete notification of all cases occurring, there should be assurance that something would be done for the persons notified.—Councillor GRIFFITHS (West Riding of Yorkshire) said that Dr. Mess's figures only applied to the years 1921–25, and that since 1926 the mining population were suffering from tuberculosis more than ever owing to malnutrition, unemployment, and low wages.—In reply to the last speaker, Dr. S. G. MOORE (M.O.H., Huddersfield) pointed out that while privation and poverty play an essential part in tuberculosis as well as other diseases, the children of the rich also suffer and die from the fell disease.

The Factors that Produce Adult Pulmonary Tuberculosis.

Dr. EDOUARD RIST (Paris), in introducing the subject, said that the old traditional idea that consumption was due to some mysterious constitutional or hereditary predisposition must be abandoned. In civilised communities the adult was not, like the infant, virgin soil for the tubercle bacillus—disease in the adult was not the result of a first infection. Infection occurred in childhood, leaving the subject healthy and immune for years until, under the stress of adverse conditions, he more or less suddenly fell a victim to the disease. Physical vigour in itself did not protect against tuberculosis; the intensive training of the pugilist offered no guarantee against the disease. While a rational and well-ordered, well-regulated mode of living would undoubtedly reduce the liability to infection, it must be admitted that the actual causes of a breakdown were largely obscure; only a few factors were more or less definitely known or suspected, and it was left to the coming generation to discover those of which we were to-day utterly ignorant.

Dr. A. F. BERNARD SHAW (College of Medicine, Newcastle-upon-Tyne) followed with a contribution from the pathological side. His paper dealt with the value of the experimental method and the phenomena of virulence, resistance, and allergy in the study of tuberculosis. Mentioning that it was extremely rare in civilised communities to find in adults progressive pulmonary lesions resembling those found in the primary infection of childhood, he maintained that the rarity of such cases was in strong support of the idea that the bacilli of childhood infection do not commonly survive to adult life in numbers sufficient to serve as the origin of adult phthisis, and was of opinion that pulmonary tuberculosis occurring in adolescence or later was due to reinfection from without.

Dr. C. G. R. GOODWIN (Medical Superintendent, Barrasford Sanatorium), dealing with the subject from the medical standpoint, said that infection with the tubercle bacillus, though an essential factor, was not the sole cause of manifest pulmonary tuberculosis, and was of opinion that active lung tubercle in adult life was not due to a new or recent infection, but was an extension from a pre-existing focus, laid down in childhood, and that this extension and spread were due to adverse environmental conditions in the home and/or prolonged chronic fatigue. To reduce the incidence of the disease, he advocated adequate separation of advanced cases from children, and improvement of the housing and social conditions of the poor. Further, he advised that the public should be clearly taught, first, that those who gave themselves no leisure were prone to develop a state of chronic fatigue with loss of weight and increased liability to tuberculosis; and, secondly, that when maintained loss of weight occurred medical advice should be sought.

Sir THOMAS OLIVER (Vice-Chancellor, Durham University) dealt with the industrial aspect of the disease and said that occupation might favour its development by locally predisposing the pulmonary soil for the reception of the bacillus and by reducing the general resistance of the worker. Speaking of the relationship of pulmonary disease to dust inhaled at work, he instanced the decreased incidence of phthisis among steel-grinders as a result of improved methods of ventilation and changed methods of operating. He considered the granite industry at home and abroad, and directed special attention to the work of the South African Miners' Phthisis Medical Bureau. He also detailed some experiments conducted by himself which showed that the finest particles of dust did not absorb water, and expressed the opinion that those particles were the cause of silicosis where rock-drilling was accompanied by water sprinkling.

Instruction of the Public, the Tuberculous, and the Medical Student.

Dr. WILLIAM BRAND (Medical Commissioner to the Association) gave an address on a Scheme of National Propaganda Regarding Tuberculosis. Quoting the aphorism of the late Dr. Herman Biggs that "health is purchasable," Dr. Brand said that this was the case for propaganda in a nutshell provided we knew what to buy. It was incumbent upon those with specialised knowledge to share it with the public and instruct the masses in tuberculosis, its causes, prevention, and the general principles of treatment. Antituberculosis propaganda must not be intermittent, but should be constant and insistent. The subject should be approached through every possible channel—e.g., the schools, the Boy Scout movement, the press, and the medical and nursing professions—besides the official public health services.

Dr. A. H. MACPHERSON (Medical Superintendent, Burrow Hill Sanatorium Colony) read a paper on the Combined Treatment and Technical Education of Tuberculous Youths. The Burrow Hill Sanatorium Colony had been reorganised, he said, to provide combined treatment and technical training for youths between the ages of 14 and 19 years. Courses of training were given in gardening and clerical work. The cost, £2 10s. per week, was defrayed by the authority responsible for the patient's admission. Forty-six youths from various parts of the country were in residence and the results were very hopeful, but the success of the scheme depended largely upon the coöperation of the local care committees and their ability to find permanent employment for the trainees. —Dr. NOEL BARDSWELL (Medical Adviser to the London County Council) followed with a glowing account of the colony, its situation, surroundings and its work, and expressed the opinion that the patients should derive great and lasting benefit from residence in the institution.

Prof. THOMAS BEATTIE (Durham University), speaking of the Teaching of Tuberculosis to Undergraduates, deprecated the institution of special courses in tuberculosis, and expressed the fear that the general standard of medical education would suffer if more special subjects were included in the curriculum. He held that tuberculosis was so intimately connected with general medicine and surgery that teaching in it could be best imparted by the professors of these subjects supplemented by instruction gained in the bacteriological and pathological departments. He hoped that the present inadequate supply of clinical material would be increased when the poor-law hospitals were taken over by the local authorities.—Dr. FERGUS HEWAT (Edinburgh University) said that the teaching of tuberculosis to undergraduates was regarded as an essential part of the medical curriculum in all Scottish universities. Such teaching should be given in the final year of study.—Dr. JAMES CROCKET (Glasgow University) said that only two things had to be considered: (1) Was there the need? and (2) Was there the time? He maintained that the need and the time for special study of tuberculosis both existed, and outlined the course at Glasgow.—Dr. A. TRIMBLE (Belfast) thought that the teaching of tuberculosis was so necessary that it would pay the municipalities to subsidise a lectureship in every medical school.—Dr. M. DAVIDSON (Brompton Hospital) remarked upon the lack of clinical material for the teaching of pulmonary tuberculosis in the general hospitals and advocated closer coöperation between these and the poor-law hospitals.

Dr. W. H. DICKINSON (Newcastle-upon-Tyne) read a paper on the

Training of Tuberculosis Medical Officers.

After the usual house appointments, he advised a period of general practice, followed by a post in some department of the public health service other than tuberculosis, so that the prospective tuberculosis officer might be imbued with spirit and ideals of prevention. A junior appointment in a large sanatorium or special "chest" hospital should precede application for a post as assistant tuberculosis officer. Dr. Dickinson laid special stress upon the importance of post-graduate study in general medicine as well as tuberculosis and the recommendations of the Astor Committee regarding study leave were quoted.—Dr. J. D. LEIGH (Sunderland) said that special training in surgical tuberculosis was necessary, and pointed out that some hospitals contended that non-pulmonary tuberculosis should be prevented and treatment ought to be a direct charge on the municipalities.—Dr. F. J. H. COUTTS (Ministry of Health) emphasised the importance of the subject and paid a handsome tribute to the zeal and enthusiasm of the members of the tuberculosis service under difficult conditions.—Dr. J. CROCKET (Glasgow) said that the course of study for the D.P.H., as at present constituted, was not of much value to the tuberculosis officer. He suggested that the value would be enhanced if the examination could be modified to allow candidates to pass in special subjects—e.g., tuberculosis.—Dr. J. C. GILCHRIST (Welsh National Memorial, Cardiff) pointed out the value of contact with students to tuberculosis workers, and mentioned that the tuberculosis officers and sanatorium superintendents were recognised teachers in the University of Wales. He also alluded to the value of the quarterly meetings of the staff of the Welsh National Memorial Association, with clinical discussions and pathological demonstrations.

Dr. HARLEY WILLIAMS (Assistant Medical Commissioner, N.A.P.T.), in the course of an address on Methods of Local Propaganda Regarding Tuberculosis, said that it was only in recent years that propaganda had come to be regarded as a legitimate part of the campaign against disease. The greatest difficulty was the ignorance surrounding the question of tuberculosis, and he urged a great extension of the teaching of the subject to the lay public, especially through the medium of the schools.

The session concluded with an address on Dentistry in Relation to Tuberculosis by Dr. WILLIAM GUY (Edinburgh), in which he laid emphasis upon the importance of preventive measures before infection occurred, and upon the necessity of an efficient dental service at all sanatoriums, clinics, and dispensaries.

A HOSPITAL BANNER.—A banner made by the patients of Grangethorpe Ministry of Pensions Hospital in 1927, in memory of the 330 patients who have died within its walls, has been placed in St. James's Church, Birch-in-Rusholme, Lancashire, and dedicated by the Bishop of Middlesex. Grangethorpe, which was originally a military hospital, ceases to be a Ministry of Pensions institution at the end of the present month.

WEST BROMWICH GENERAL HOSPITAL.—The report of the medical committee for the year ended on June 30th last, signed by Dr. L. A. Dingley, the chairman, states that the 1683 in-patients formed a "record." The general death-rate was 4·3 per cent.; 2·3 per cent. died within 48 hours of admission. In the casualty department 10,171 cases were treated, and the medical staff urge the importance of replacing this building, which is out of date and unsuitable to the heavy demands upon it.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Nursing and Midwifery.

ADDRESSING the annual meeting of the Midlothian County Nursing Association, Dr. Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland, spoke of the need for a radical reorganisation of the training of nurses. At present any girl looking forward to making a comprehensive profession of nursing would be in a position of tutelage for ten years, including three or four years of general training, three years' experience of fevers, one year of maternity work, a year at mental diseases, and so on. The thing was ridiculous. He looked forward to the time when a woman going in for nursing would get a comprehensive training within four to five years. He aimed at the orientation of the county service of Scotland round the medical schools of Edinburgh, Glasgow, St. Andrews, and Dundee and Aberdeen. This would provide the utmost efficiency, with reasonable economy. A million and a half pounds a year were being spent on a national health insurance system that was breaking down at the vital point—where the person needed nursing and hospital treatment. In the women's wards of the general hospitals 75 per cent. were there to seek remedy from the results of the present state of midwifery practice in Scotland. These things could be put right by a proper system of prenatal service, which the local authorities were called upon to provide, and by a proper midwifery service; but it could only be done by a combination of the voluntary and official organisations. They had met the voluntary hospitals, and got them organised into regions. When they knew what the voluntary systems could do, they would say to the local authorities: "You fill up the gap." The same thing held as regards this great nursing service.

Highlands and Islands Medical Service.

The Secretary of State for Scotland has received Cabinet sanction to introduce a Bill to amend the Highlands and Islands Medical Service Act. Under this Act an annual expenditure of £42,000 was authorised, but after 15 years' experience it has been found that the sum is too small for the schemes already developed, and the annual total expended for the last few years has been over £60,000. The new Act will probably provide for a larger annual sum, and may contain some amendments indicated by experience. The medical service (including nursing) arranged under the Act is, at least in Great Britain, a unique experiment in so-called "State medical service." Its success is now recognised.

The Glasgow Mental Colony.

A considerable time ago the Glasgow District Board of Control decided to convert the house and grounds of Lennox Castle, Stirlingshire, into a colony for the care and treatment of mental defectives. The scheme is one of the largest ever undertaken by the Glasgow Board, which will now be able to classify their mental defectives in a much more satisfactory way. Lennox Castle will accommodate 1000 patients, and this will probably meet the needs of Glasgow and the west of Scotland for some years. Stone-Yetts, another large colony both for epileptics and mental defectives, which has been worked on modern lines under Dr. Chislett for many years, will now be available for other poor-law purposes. With the Gogar-Burn Institutions for Edinburgh and the east, Lennox Castle and Stone-Yetts in the west, and the Royal Institution at Larbert in the centre, Scotland is rapidly making up leeway in her provision for the selected feeble-minded and their permanent care.

The Young Offender.

Mr. Tom Johnston, Under Secretary of State for Scotland, at the annual meeting of the Glasgow Council of Juvenile Organisations, said that he thought there was great need for more careful examination into the causes and prevention of crime. The theory of public and legal vengeance was archaic. It got nowhere at all, and a deterrent theory was getting but a very short distance. It had been stated in America that nine-tenths of the criminals in prisons ought never to have been there. He had heard the chairman of the Glasgow Parish Council say that three-quarters of the unfortunates who reached the Council under the label of "mentally deficient" ought never to be there either. In view of such statements he thought it was time that they bestirred themselves municipally in an endeavour to prevent these institutions from being choked with boys and girls, young men and women, and also old men and old women, who ought never to have been allowed to drift that length.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Stresemann's Illness.

THE late Mr. Stresemann suffered from nephritis, which was discovered about six years ago. Notwithstanding the great strain of his political work, he felt comparatively well until he contracted pneumonia in 1926. After that his general health deteriorated and he nearly died of renal insufficiency in 1928. He recovered sufficiently to take up again the burden of his office as Foreign Minister, but attacks of cardiac weakness gradually developed and on his journeys to conferences abroad he had to be accompanied by his medical attendant. At the Hague Conference this summer, which was associated with an enormous amount of work and much excitement, his illness grew worse, and his foreign colleagues noticed a great change in his condition. After the Hague and Geneva Conferences he took a short holiday at Vitznau on the Lake of Lucerne. A few days before his death he returned to Berlin, where party troubles induced him to leave his bed against medical advice. He was not a very obedient patient and it was very difficult for his medical advisers to make him follow their prescriptions. He indulged in smoking and was not a total abstainer, contrary to dietetic rules. On the evening of Oct. 2nd he had a cerebral hæmorrhage with paralysis of the left side. His medical attendant, Prof. Zondek, and Prof. Kraus were called in, but he died six hours later without regaining consciousness.

Lead Poisoning as a Legacy of Gunshot Wounds.

Notwithstanding the enormous number of gunshot wounds received in the late war in which bullets or fragments of metal remained in the body, the number of cases of lead poisoning from this cause has been very small; in fact no more than eight seem to have been recorded. In the *Deutsche Zeitschrift für Chirurgie* Dr. Hage has lately described a new case, in which the patient was a meat inspector who had been wounded in the war in German South-West Africa 22 years ago. In 1926 he complained of tremor of the fingers, headache, and colics, and gradually his complexion got the characteristic lead pallor, whilst a blue line developed on the gums and there was weakness of the extensor muscles. The presence of basophile erythrocytes and an increase of hæmatoporphyrin in the urine left no doubt of the diagnosis of lead poisoning, and by radiography it was ascertained that there were some splinters of metal in the femur. As the man had nothing to do with lead, the poisoning was evidently due to those splinters. Hage draws attention to the lapse of 20 years since the injury, and suggests that this time interval may explain why but few cases of lead poisoning have so far been noticed among men wounded in the late war.

Boycott of a Medical Man.

A medical man whose motor-car was damaged by a railway car claimed damages which according to the railway company were excessive. The company thereupon told its employees not to consult this doctor, and the works committee, under pressure from the company, also recommended workmen to go to other practitioners. The doctor accordingly brought an action for damages against the company and won the case. By an injunction the company was first restrained from boycotting the plaintiff and was then ordered to pay him damages for the loss of a part of his practice. In judgment the court described the behaviour of the company as highly immoral and a kind of revenge. If they regarded the doctor's claim as too high their remedy was to apply to the courts or settle the matter extra-judicially. The claim of the medical man having nothing to do with his professional skill, they were obliged to recover the damages done to him. This judgment will certainly meet with the approval of the profession in general, since boycott of medical men for reasons not connected with their profession has also been tried on other occasions, though not in such an open and silly way.

Occupational Diseases of Dentists.

Dr. Mosenthal, a Berlin orthopædist, recently read a paper on the occupational diseases of the dental profession. Among these may be mentioned wounds of the fingers by bites, with or without infection, and dermatoses caused by frequent washing of the hands with sublimate of mercury. By over-exertion of certain muscles used in dental work neuroses may be caused, whilst conditions such as genu valgum and genu varum may be produced by long hours of standing. The position of the dentist at the operation chair sometimes leads to scoliosis, and flat-foot may develop as a sequel to relaxation of the muscles and ligaments. Varicose veins are also very common. Mosenthal advises dentists to remain seated at their work, as many surgeons already do in performing operations, and he recommends for that purpose a rotary chair. Certain pauses in the work when the dentist should rest in a sitting position are necessary, and he must also see that he has adequate shoes.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Post-vaccinal Encephalitis.

THE European experience with post-vaccinal encephalitis is the subject of extended comment in the current *Annals of Internal Medicine*, which reflects the very general reluctance of American pathologists to believe that a pure vaccine virus can produce encephalitis. It is not long since Dr. Richard Thompson, of Columbia University (a Fellow in Medicine of the National Research Council), reported his failure to produce vaccinal encephalitis in rabbits with a testicular virus. With direct intracerebral injection attempts to adapt the virus by brain and brain passage, at seven day intervals, gave negative results. Alternating brain and testicular passage, as used originally by Levaditi, was no more successful. Thompson considered that a possible explanation of the discrepancy between his results and those of so many European workers might be in variations in the strain of virus employed; that some would produce encephalitis without difficulty, others only after adaptation, and *still others not at all*. He mentions also the theory of Camus that the vaccine virus may be contaminated by some unknown neurotropic virus. It is to this latter theory that the editorial above mentioned very definitely leans. May not the unknown virus be simply the normal virus of rabbit encephalitis carried over with rabbit lymph, and may it not produce encephalitis in susceptible human beings? Up to the [illegible] four cases of post-vaccinal encephalitis have been reported in the United States. It is urged that, until the question of the ætiology of this disease is settled, the use of rabbit lymph in vaccination should be stopped.

A Healthy Summer in New York.

This summer has seen unusually healthy conditions in New York State. July saw two records broken: the infant mortality-rate of 48 per 1000 live births is the lowest July rate yet achieved, and represents a ratio of only 7·8 per cent. of all deaths; tuberculosis mortality (78·9) is also the lowest ever recorded in this month. The reported cases of tuberculosis show an increase of more than 400 over the corresponding month of last year, a striking example of improved diagnosis going hand in hand with falling mortality. The increase of 700 in the reports of syphilis is no doubt partly due to improved reporting, as well as to the fact that the venereal diseases, formerly reportable only by laboratories, have now been made reportable by physicians. Other changes made in the sanitary code relating to the reporting of disease are the dropping of erysipelas from the list of notifiable diseases and the addition of tularæmia and undulant fever. Five cases of undulant fever were reported during the month.

The Study of Morbidity.

Vital statisticians have for some years been pointing out that mortality statistics are a very poor index of the amount of sickness in a community. New York State has introduced a system of reporting sickness which already enables it to publish at regular intervals some very informing statistics. The U.S. Public Health Service is now projecting the establishment of a morbidity registration area, not only with the object of collecting important data for statistical manipulation, but also with the more immediate object of raising the standard of the reporting of notifiable diseases. As a basis for discussion it is suggested that the reporting of the following six diseases should be considered a basis for admission into the new registration area—viz., diphtheria, infantile paralysis, scarlet fever, small-pox, typhoid, and tuberculosis. The suggested minimum of efficiency which each State would have to reach before admission is 75 per cent. of all clinically recognised cases. The funds available to the public health service for this work at the present time are not large, and the success of the project will depend largely upon the coöperation accorded by the local units. If that is generously accorded it is hoped that the proposed registration area may be established by July of next year. In the meantime some valuable data are being correlated in the statistical division of the public health service from reports received from 35 different industrial sick benefit associations. One limitation of these industrial statistics is the absence from them of diseases for which benefits are commonly refused, including the venereal diseases and those which result from infractions of the law.

Phenol Wastes and the Water-supply.

The common practice in this country of adding chlorine to municipal water-supplies has given great importance to the elimination of phenol wastes on account of the fact that even small traces of phenol, when combined with a minimal quantity of free chlorine, will give to the water a most unpleasant taste. During the past five years a campaign has been conducted to exclude phenol wastes from the Ohio river. Although reliance has been placed upon education and persuasion unarmed by any legislative powers, the campaign has met with such success that to-day only four coke plants are discharging phenol wastes into the river in place of 17 such offenders in 1924. A careful record has been kept of the appearance of chloro-phenol tastes in the meantime, as well as of the flow of the river. There is a greater loss of concentration in the phenols as they pass down stream than can be accounted for by increasing dilution—the result, it may be, of biochemical oxidation.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1928 statistics of six towns:—

Name of town and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Croydon C.B. (214,800)	15·7	11·0	0·96	1·52	1·5	1·9	53/20	28	3·9
Coventry C. (161,600*)	14·4	9·6	1·0	1·24	1·5	1·5	66/30	33	4·7
Derby C.B. (138,900)	19·3	10·9	0·93	1·28	1·1	1·7	60/30	26	7·5
Preston C.B. (127,100)	15·1	12·7	0·95	1·41	2·2	2·0	91/42	34	6·3
Northampton C.B. (94,070)	13·9	11·3	1·06	1·59	1·5	2·3	53/25	21	3·0
Paisley B. (88,140)	20·2	13·1	1·33	1·23	2·3	1·6	105/49	50	4·4

* The city was extended on April 1st. The above is a special estimate for statistical purposes. The mid-year estimate for the extended city was 168,134.

C. = City. C.B. = County Borough. B. = Burgh.

Croydon.

Dr. Oscar M. Holden describes Croydon as an originally residential town, which is gradually assuming an industrial character. The chief industries are iron foundries for bell-casting and engineering, and the London terminal aerodrome is within the borough. At the request of the Ministry, three members of the medical staff have performed duties at the aerodrome under the Aliens' Order, 1925. The cost of this service does not fall on the rates, and Dr. Holden points out that if the work is to be done properly a full-time medical officer will be required in the near future. Dr. Holden's experience hitherto has been in northern industrial towns, and he comments on the comparatively small figures of deaths due to respiratory diseases in towns like Croydon, but adds a word of warning that a rise in the death-rate from these diseases is likely to occur in south-eastern England owing to increasing urbanisation and industrialisation unless adequate steps are taken to prevent atmospheric pollution.

St. Mary's Hostel provided by the Croydon Mothers and Infants Welfare Association, has 17 beds for maternity cases, of which the corporation retain 15, in return for an annual grant of £1800. All cases, other than emergencies, have to pass through the municipal antenatal clinics. During 1928 the 314 admissions to the municipal beds included 11 emergencies; 193 cases had to be refused. Thanks to a legacy of £7500, aided by a municipal grant of £3000, this institution is to be extended by the erection of a modern maternity block of 32 beds, of which the corporation will rent 30. Dr. Holden mentions that the closer linking up of antenatal, natal, and postnatal activities is perhaps the most urgent matter for consideration in the maternity and child-welfare scheme. One of the great lacks at present is suitable accommodation for mental deficiency cases, and the solution suggested is that Croydon should combine with other authorities to provide a large institution or colony.

From the school report we learn that ionisation and rheumatism clinics have been established. The former was opened in July under the charge of Dr. J. D. McLaggan. The cases dealt with, 48 in number, all had obstinate ear discharges. None had lasted less than six months, 1 six to twelve months, 4 one to two years, 14 two to five years, 11 over five years, and in 11 the duration was unknown. The results appear to be satisfactory so far, but no figures as to cures can be given as that implies at least six months freedom from discharge. The rheumatism clinic had a flying start on April 30th as for 18 months note had been made of suspects during routine school inspections. The full coöperation of parents and teachers has been obtained. There were 314 cases examined, of which 243 were classed as rheumatic. Interesting particulars are given of the incidence of the various rheumatic manifestations, family histories, and environmental conditions. There has been as yet no provision made for institutional treatment, but a few of the children were sent to West Wickham Heart Home.

Coventry.

Dr. E. H. Snell presents his thirty-second and farewell report, and appropriately includes in it a table giving the principal vital statistics of his first annual report for 1897 and of that for 1928. The comparison shows that the population has nearly trebled; the birth-rate has declined by 54 per cent., the death-rate by 43 per cent., infant mortality by 58 per cent., and the phthisis-rate by 23 per cent., while the mean age at death has gone up by 12·8 years. Among the advantages of Coventry, Dr. Snell enumerates a ring of commons on its borders, an almost non-existent smoke problem, a good average standard of living owing to regular employment, and the fact that two-thirds of the houses have been built in the last 30 years in accordance with modern by-laws. The insignificance of the smoke problem, he points out, is helped by the facts that practically all the works obtain their power from the electricity department, and by the large use of gas-stoves for heating and cooking. There are 40,000 gas-cookers and 14,000 gas-fires for slightly over 38,000 houses, and during the late coal stoppage there were less than 100 applications for coal permits on the ground of having no gas-cooker. Since 1916 practically nothing has been possible in the way of closing unfit houses. During the war the city was flooded with thousands of munition workers, and since the war there has been no alleviation in the great demand for houses, which is a long way from being satisfied. Some thousands of new houses could be let if they existed. Also a larger staff of sanitary inspectors is needed to deal with decay and dilapidation in the older property.

The recent extension of the city boundary raised its acreage by 4147 to 12,878 acres and the population of the added area at the middle of the year was 26,134. New problems have thereby arisen. Pig-keeping, except in such places as allotment gardens, was prohibited in the old city under a local Act of 1790, but pig-keeping in the rural added area has been an established custom from time immemorial. Other problems are polluted shallow wells and wooden shacks of all kinds used as houses. Again, there were only six cow-keepers in the old city supplying about 260 gallons per day, but the milk produced in the extended city is estimated at 1387 gallons per day. More than half the total quantity is delivered in bottles, the greater portion being pasteurised or sterilised. The question of institutional accommodation for mental defectives is a matter of growing importance. Owing to the generosity of the public to the organisations for the blind, the municipality only provides about a quarter of the amount expended in assisting unemployable blind persons. Progress has been made in the abattoir question. An ideal site has been approved close to the railway and to the cattle market, and it is proposed to erect a thoroughly up-to-date building, which will enable all the private slaughter-houses to be closed. Curiously enough the site, which is now approved, was under consideration 40 years ago for a similar purpose but on a much more limited scale.

The deaths from diphtheria show an increase recently. In 1926 there were 5, in 1927 21, and in 1928 42. The case fatality per cent. during these three years has been 5·2, 11·3, and 16·7. Immunisation has been recently adopted for the nursing and domestic staff of the hospital, and is being pushed at the welfare centres and in selected schools. The notifications of encephalitis lethargica numbered 8 and the deaths 11. There were 110 definitely known cases of small-pox. One 9-year-old girl, who had a very mild attack with other members of her family, developed acute primary pneumonia, which proved fatal, a few days after admission to hospital.

Derby.

Dr. Albert E. Brindley says the most unsatisfactory statistical fact is the increase in maternal mortality. The death-rate from puerperal sepsis alone was 3·0 per 1000 births. Antenatal work is only on a small scale as yet; the clinic was attended by 207 expectant mothers and the total births in the borough were 2070. Dr. Brindley objects to the term "filth-disease" being applied to small-pox, as it has affected some of the cleanest persons living in the cleanest houses in the town, and the use of the term may not only cause distress to sufferers but lead to concealment of cases. He mentions that counsel for one of the property owners at a recent improvement scheme inquiry tried to make a strong point of the fact that no small-pox had occurred in the area. There were 212 known cases of small-pox and no deaths during 1928. The corporation, in their 1929 Bill, are seeking powers to require information to be furnished under a penalty, when such information is deemed necessary for preventing the spread of small-pox and other infectious diseases.

In the recently added area 30 samples of well water from 28 wells were examined and only 8 were reported as fairly satisfactory for drinking purposes. The new houses erected during the year numbered 198, of which 63 were municipal. Pitiful applications continue to be received at the Health Office for municipal houses, and many cases of overcrowding come to the knowledge of the inspectors in visiting notified infectious diseases. During the year the corporation made a first attempt to deal with two slum areas. The first area comprised 120 houses with 482 occupants; the second 80 houses with 379 occupants. The intention was to rehouse the displaced tenants. The inquiry was held in October, but unfortunately, owing to legal difficulties, the efforts of the corporation have been, for the time being, at any rate, nullified. At the beginning of 1928 there were about 1700 objectionable tub or pail closets. These have now been practically all dealt with, the corporation paying a subsidy of £8 each for their conversion into water closets. Dr. Brindley again records the need for new premises for the health offices and for adequate and suitable accommodation for maternity and child welfare work.

Preston.

Dr. F. A. Sharpe points out that the main attack is no longer on the environment and that even the slum problem is a comparatively minor one in Preston, the chief aim being to see that a vast amount of rapidly ageing working-class property is maintained in reasonable condition. Work in the interest of the individual will receive, he says, a fresh inspiration and impulse from the Local Government Act of 1929. The care of the poor and their medical treatment will be in the hands of one authority, and there will be unification of public medical services and coördination of hospital treatment and of medical services for infants, mental defectives, and blind persons, opening out fresh fields of endeavour. At present the various departments are separately housed, and the outstanding need is the creation of a central office in which the administrative work of all branches can be organised and controlled.

The houses erected since 1911, numbering 3703, are more than sufficient to contain the natural increase of the population on the basis of 4·3 persons per house, which was the density at the 1921 census. Notwithstanding, bad housing conditions are to be found. When the corporation build houses they finish the roads, but this is not the case for private enterprise houses. The majority of persons who have bought "private" subsidy houses have stretched their resources to the utmost to do so, and many are not in a position to face the cost of road dedication, but in the absence of proper roads their property is bound to deteriorate. Less than 4 per cent. of the milk is produced in the borough. The biological examination of 257 bulk samples of milk showed that 28, or 10·9 per cent., were tuberculous. Dr. Sharpe shows that the present method of following up tuberculous milk samples is no incentive to the outside farmers to produce tubercle-free milk. One of the 28 tuberculous samples was from a farmer, who had already been twice dealt with. When his farm was visited in 1928 two tuberculous udders and one cow with advanced tuberculosis were found. These animals were obviously diseased and should have been notified under the Order.

The births in the borough numbered 1910 and the expectant mothers who attended the antenatal clinic were 311, of whom 85 were sent by midwives. An arrangement is now in force by which if a midwife-sent case has to be referred to hospital the midwife receives half her fee as compensation. Four midwives were so compensated during the year. A questionaire sent out during the year brought out much difference of opinion among medical practitioners and others as to whether prolonged industrial depression has affected the health of working-class mothers. The school report shows the need for the increase of the dental staff, and that the orthopædic scheme begun in the autumn of 1927 has done a satisfactory year's work.

Northampton.

Dr. Stephen Rowland reports that the chief interest has been centred in the small-pox outbreak which began in July, 1928, and is still in existence in the middle of 1929. During 1928 there were 82 cases with no deaths, and up to June, 1929, there had been altogether 450 cases. Dr. Rowland's experience suggests that vaccination confers immunity for at least 20 to 25 years, and that cases unrecognisable by their mildness may cause the disease in others in a much more severe form. Bacterial examination of the water-supply showed an unexplained increase in coliform organisms during the later months of the year. Dr. Rowland comments on the fact that it is quite common for persons suffering from active tuberculosis to marry. He cites one example, where a young married woman in the last stage rose from bed to attend the wedding of her sister, also suffering from active phthisis. The first-named died a few days after the wedding, her death being followed a few weeks later by that of her child from tuberculous meningitis. An X ray apparatus is needed at the dispensary for diagnosis and for the control of artificial pneumothorax. No attempt at the clearance of any large slum area has been possible. Of 24 houses condemned during 1928 14 were still occupied at the end of the year, owing to the lack of other accommodation. Dr. Rowland points out that when a closing order is made the tenants are in no hurry to leave as they are able to live rent-free.

Paisley.

Dr. G. V. T. McMichael describes a gallant fight against overwhelming odds. The proportion of one- and two-roomed houses is 63·4 per cent. A survey of 3083 of the oldest houses towards the end of the year showed that more than 25 per cent. were overcrowded, some of them being occupied by two or three times the number of persons they were fitted to accommodate. The average inclusive rent of a one-roomed house is 10*s.* per month, and of a two-roomed 25s. per month, and many of the occupants are not in a position to pay much more. 362 of the houses inspected were only fit for demolition. After considering a report on these lines the burgh council decided to proceed with a scheme for 200 two-roomed houses to be let at rents which the lower paid working-classes can afford. Another difficulty confronting the health department is that the clinics are overcrowded, and that the medical staff is inadequate for the provision of the extra sessions needed. The child welfare centres are being used as out-patient departments, and in Dr. McMichael's opinion the only remedy is the extension of the insurance service to dependents. One of the bright spots is Barshaw Municipal Maternity Hospital, which provides ample accommodation for both antenatal and labour cases. More mothers need to be attracted to the antenatal clinics, and a separate postnatal clinic is required for them. More dental work is wanted especially among the pre-school children whose teeth are "in a deplorable state." The present arrangements do not attract female patients to the V.D. clinic, and Dr. McMichael suggests that an extra session should be provided in the evening. The provision of a joint county sanatorium for non-pulmonary tuberculosis and the substitution of an up-to-date isolation hospital on the outskirts for the old burgh fever hospital have been long awaited but are now apparently approaching realisation.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 5TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 97 (last week 108); scarlet fever, 2913; diphtheria, 1402; enteric fever, 83; pneumonia, 853; puerperal fever, 45; puerperal pyrexia, 107; cerebro-spinal fever, 2; acute poliomyelitis, 29; acute polio-encephalitis, 4; encephalitis lethargica, 15; dysentery, 25; ophthalmia neonatorum, 116. No case of cholera, plague, or typhus fever was notified during the week.

The notifications of small-pox this week, as three weeks ago, are again below the 100 level which has been maintained since September, 1928.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Oct. 7th–8th was as follows:—Small-pox, 141 under treatment, 4 under observation (last week 143 and 10 respectively); scarlet fever, 1999; diphtheria, 1969; enteric fever, 27; measles, 165; whooping-cough, 163; puerperal fever, 25 (plus 9 babies); encephalitis lethargica, 125; poliomyelitis, 6; "other diseases," 15. At St. Margaret's Hospital there were 18 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox or enteric fever, 13 (3) from measles, 4 (1) from scarlet fever, 30 (4) from whooping-cough, 34 (9) from diphtheria, 189 (41) from diarrhœa and enteritis under two years, and 32 (7) from influenza. The figures in parentheses are those for London itself.

Of the deaths from diarrhœa (the number of which has now reached its fastigium) 17 were reported from Birmingham, 15 from Hull, 11 from Liverpool, 9 from Middlesbrough, 7 each from Salford and Leeds, 6 each from Manchester and West Ham, while Glasgow, Dublin, and Belfast reported 9, 8, and 10 respectively.

The number of stillbirths notified during the week was 269 (corresponding to a rate of 43 per 1000 births), including 53 in London.

A NEW SUNDERLAND HOSPITAL.—A new Monkwearmouth and Southwick hospital to contain 120 beds is about to be built at Sunderland at a cost of about £95,000. Sir John Priestman, shipbuilder and chairman of the hospital, who has already given £5000 towards the building fund, has announced that he will give a further £10,000.

"Audi alteram partem."

GENERAL MEDICAL COUNCIL.

ELECTION OF DIRECT REPRESENTATIVES FOR SCOTLAND.

To the Editor of THE LANCET.

SIR,—The Registered Practitioners of Scotland will shortly be called on to elect a Direct Representative to the General Medical Council, and we, the undersigned, have ascertained that Sir Norman Walker, who has served with so much acceptance as our Representative for over 20 years, is willing to submit himself again as a candidate.

We recall with satisfaction the record of valuable and responsible work which he has achieved as our Representative. That he is a valued member of the Council is shown by the many important positions he occupies, and the special Missions with which he has been entrusted. On the Council he is Chairman of the Business and of the Examination Committees, and a member of the Executive, Finance, and Penal Cases Committees. In 1927, on the invitation of the Government of India, he visited for the second time the Medical Colleges and Universities of that Country, and reported on the progress made since his first visit in 1922; and last year, on the invitation of the Council of Medical Education and Hospitals of the American Medical Association, he revisited the United States, delivered Addresses on Medical Education and on Medical Registration and Legislation in Great Britain and in the British Dominions, and took part in the deliberations of their Annual Conference.

As Chairman of the Examination Committee he had important duties in connexion with the last Official Inspection of the Final Examinations of all the Licensing Bodies in this Country in Medicine, Surgery, and Midwifery, and should he again be returned as our Representative, it is probable that these will be again entrusted to him in connexion with the new cycle of Inspection which begins next year. We therefore venture to suggest to our medical colleagues in Scotland that Sir Norman's candidature might well be afforded our hearty support at this election.—We are, Sir, yours faithfully,

C. E. DOUGLAS (St. Andrews).
P. T. HERRING (St. Andrews).
D. WATERSTON (St. Andrews).
D. E. DICKSON (Lochgelly).
J. MACDONALD (Cupar).
J. J. WILSON (Anstruther).
A. L. CURROR (Kirkcaldy).
J. LANGWILL (Kirkcaldy).
G. WILLIAMSON (Aberdeen).
J. MARNOCH (Aberdeen).
J. F. CHRISTIE (Aberdeen).
J. B. SIMPSON (Golspie).
J. MURRAY (Inverness).

MALIGNANT TUMOURS IN THE FOWL.

To the Editor of THE LANCET.

SIR,—I was much interested in the article on this subject by Dr. A. M. Begg and Dr. W. Cramer in your issue of Oct. 5th. My experience certainly supports the view of these workers that the production of fowl sarcomas of the type Rous No. 1 by embryo emulsion and chemicals, as reported by Carrel and other workers, owes its success to contamination by tumour material. I have made repeated attempts to produce tumours by the inoculation of fowls with embryo pulp and arsenious acid; in no case has a malignant tumour been produced by this means. In this laboratory we always keep a supply of a dozen or so small sterile mortars for grinding up tissues, and all the apparatus used is sterilised by heat; this fact has, no doubt, accounted for the lack of success in the production of tumours with arsenic.

We have had, up to the present, probably about 2000 birds with experimental tumours, chiefly Rous sarcoma No. 1, through this laboratory, and on two occasions the tumour has appeared on birds which had not been inoculated experimentally. These birds developed tumours (Rous No. 1) on the head, and the infection could be attributed to inoculation by a peck, since they had been in a pen in which there was a bird with a superficial tumour which had become ulcerated and been pecked by other fowls.

Considering the ease with which a tumour can be produced by a minute quantity of material from a virulent sample of this sarcoma, it is rather surprising that there is so little evidence of infectivity in laboratories where considerable numbers of tumour-bearing fowls are housed. This absence of infectivity may perhaps be accounted for by the fact that the tumour material, either as a filtrate or in the form of small particles, loses its activity comparatively rapidly on exposure to air.—I am, Sir, yours faithfully,

S. L. BAKER.

Bland-Sutton Institute of Pathology, Middlesex
Hospital, London, W., Oct. 8th, 1929.

ANAEROBIC TOXÆMIA IN ACUTE OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—When the demonstration of Harvey, that the blood goes round and round, is recognised as being something more than an interesting phenomenon; when students of medicine really come to grasp that the flow of blood through the tissues matters to any part in question as to the individual as a whole: then, perhaps, medicine will begin to make that advance which is long overdue. At present, unhappily, such a circumstance seems to be completely disregarded. The effect of the interference to the blood-flow through the intestine—and thus through the portal vein and liver—in acute intestinal obstruction, caused on the one hand by the specific effect of the obstruction on the proximal part of the gut affected, and on the other by the effect of the straining, the tenesmus, and especially of the vomiting on the blood-flow through the whole gut and through the liver, is unconsidered by those concerning themselves with the genesis of the toxæmia arising in this state. Thus in your annotation of Oct. 5th (p. 724) no mention is made of this disturbance or of its possible effect.

No one who has had under his care a case of acute intestinal obstruction, who has watched the patient in the earlier part of the illness, has seen the operation, or inspected the patient subsequently during the recovery or at the post mortem, can have failed to recognise that in this disease physical forces are in predominant play. The disease is caused by a physical impediment; recovery depends on the removal of that cause, not on the administration of antitoxins. The reaction of the patient, his behaviour, during the illness prior to operation is one of constant and violent physical response; the patient does not lie quietly in bed, as though he were suffering simply from a rising toxæmia. He reacts greatly, constantly striving to empty the rectum, constantly straining to bring up the voluminous and ever-increasing contents of the stomach. And this goes on when the doctor is not there, all through the day and all through the night. But, according to writers on the subject, these factors do not matter, do not come into the account of a rising toxæmia, of a disturbance profoundly affecting the system, sufficing by themselves to cause exhaustion and death.

What we want is a lesson on "exhaustion" and its causes; what we want is to be taught the value—nay, the necessity—of sleep. It is plain we do not know yet the significance of either. In intestinal obstruction the student who has not yet his own reserves of observation to rely on has been taught, and perhaps is still taught, that the toxæmia of the patient—the cause, obviously, of the exhaustion and certainly of the death—is due to the rise of the *B. welchii* in the intestine; as though that mattered, as though when vital forces are ebbing the whole body does not tend to become or does not become invaded with micro-organisms. *Is it not a tragedy* to regard a complication as the primary cause of a disease? to use a hypodermic syringe when the *only* remedy is the knife? For such at least, though it may not be acted on, is the only logical conclusion of such instruction.

Some years ago I gave reasons for the view that the physical reaction of the patient plays an all-important part in the rise of the toxæmia, and showed how erroneous are the interpretations of some experimental data.[1] To the reasoning I there adduced comes now evidence to which you refer in your annotation. Certain authorities, it is stated, have repeated experiments purporting to show that the *B. welchii* or its toxins play a great part in the toxæmia, and have failed to find confirmatory evidence. Thus you declare that ". . . the original theory of intestinal absorption (of toxins) requires confirmation before it can be held to be established." The value of injecting antitoxins, you state, "has not so far been denied." My reply to that is that the value of such injections, either apart from operation or with it, has not yet been shown. If "the theoretical basis of the method, already resting on two contradictory arguments, is decidedly uncertain," I can only believe that the theoretical basis is unsound.

I am, Sir, yours faithfully,
R. H. PARAMORE, F.R.C.S. Eng.

Rugby, Oct. 5th, 1929.

THE HEALTH OF SEAMEN.

To the Editor of THE LANCET.

SIR,—The Seamen's National Insurance Society has a membership (as stated on p. 782 of your last issue) of 60,000, and *its statistics* will not be thought by anyone to be other than accurate. It occurs to me, however, that there *is* danger in concluding that the deaths and illnesses of all seamen are similar to those of the 60,000. There were 120,280 British seamen in the Board of Trade's quinquennial census, last taken on March 31st, 1926, and that makes no allowance for men on *leave* or *waiting for ships*, the 120,260 being the figure of men actually employed on that day, British seamen on British ships—twice as many as the number of members claimed by the Society.

I am, Sir, yours faithfully,
W. E. HOME.

Oct. 11th, 1929.

PROBLEMS OF EPILEPSY.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a leading article which appeared in THE LANCET for July 6th (p. 27), in which the present-day knowledge of epilepsy was ostensibly reviewed. I find it remarkable that no reference was there made to my theory that epileptic phenomena have their origin in a physiological phenomenon, a theory discussed fully in my book.[2] Although changes in the metabolic products of the body, both excreta and secreta, have been described over and over again in epileptics, subsequent work has always shown that such alterations in metabolic products occur in normal individuals, and do not stand in any direct relation to the epileptic discharges.

Even if theoretical points be waived, the deductions drawn from their consideration and presented in your leading article are, in my opinion, definitely dangerous. The contention that the administration of bromides to in aim and object: furtherance of the cause of science for the welfare of mankind.

---

[1] The Toxæmia of Acute Intestinal Obstruction: or Vomiting as a Pathological Force. Lewis and Co. 1923.

[2] Epilepsy. London: Baillière, Tindall and Cox, London, 1928.

Lord Riddell, also replying, expressed his anxiety at having to respond for so many societies, and had come to the conclusion that if he replied for one he would reply for all. *After prolonged research he had concluded that no societies had done more to advance the cause of science, or the cause of dining and wining, than the societies represented there.*

The health of the Chairman was proposed by Dr. R. L. Langdon-Down, who attributed Dr. Brackenbury's position to his loyalty to an abiding principle: that the welfare of the profession and of the public health were one and the same.

Dr. Brackenbury briefly replied.

Medical News.

University of Cambridge.—At recent examinations the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH AND DIPLOMA IN HYGIENE.

Part II.—W. J. C. Auld, G. L. Chadha, Bessie G. Jemson, *A. P. Martin, R. M. Mathew, L. N. Mathur, Isabel D. Patterson, R. S. Sandhu, S. W. Savage, A. G. Shanks, and L. R. Sharma.

* With distinction.

University of Dublin.—At a recent examination the following candidates were successful:—

FINAL MEDICAL EXAMINATION.—PART I.

Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—*G. F. Ennis, *G. A. Wray, *Brian O'Brien, *A. A. Cunningham, A. J. Harden, M. G. Leane, O. W. S. Fitzgerald, H. V. Tighe Marjorie L. Campbell, *A. D. Barber, *T. J. O'Sullivan, *Annie E. Thompson, A. D. Egan, J. A. Page, C. M. Elliott, T. H. Dockrell, R. D. Scott, and W. M. E. Anderson.

Passed on high marks.

Society of Apothecaries.—On Oct. 8th the outgoing Master of this Society, Lieut.-Colonel C. T. Samman, was placed in office for a second term in recognition of his achievements in developing the work of the Guild. After a service at St. Andrew's-by-the-Wardrobe, the Master's dinner was held in the Society's hall in Water-lane, which has now been saved from the threatened destruction by he death-watch beetle. Dr. Thomas Wakefield proposed the Master's health, and in his response Colonel Samman spoke of the efforts being made to bring the Society into the forefront of medicine.

Royal Society of Medicine: *Colyer Prize.*—In 1926 a prize was founded to commemorate the 25 years' service of Sir Frank Colyer as honorary curator of the Odontological Museum. It may be given every third year in recognition of original work in dental science completed during the previous five years by a dental surgeon educated in Great Britain or Northern Ireland who has not been qualified to practise more than five years at the date of the award. Applications for the first award should be submitted in due form not later than March 31st, 1932. The value of the prize will be about £35.

Particulars of the *annual dinner* will be found on p. 836.

Royal College of Surgeons of England—A quarterly meeting of the Council was held on Oct. 10th, with Lord Moynihan, the President, in the chair. Membership of the College was conferred on:—

C. S. Kah, Cambridge and St. Thomas's; D. Sheehan, Manchester; P. D. B. Spence, Guy's; F. R. Stansfield, Leeds; E. H. Parkinson, Birmingham; and T. J. Millin, Dublin.

It was reported that, at the Primary Examination for the Fellowship held at Toronto in August last, the following candidates had been successful:—

J. H. Beasley, Toronto; J. M. Bruner, Johns Hopkins and Rush Medical Coll.; G. A. Fleet, McGill; F. L. Horsfall, McGill; H. D. Isaacs, Manitoba; R. Marnham, Camb., St. George's, and King's Coll.; H. J. Muth, Saskatchewan; L. R. Olver, Sydney and St. Bart.'s; and V. N. Shirodkar, Bombay and Middlesex.

It is proposed to hold a Primary Examination for the Fellowship at Montreal next year.—Mr. Hugh Lett was elected a member of the Committee of Management of the Conjoint Examining Board.

On the recommendation of the Board of Examiners in Dental Surgery it was decided that after July, 1930, candidates for the Licence in Dental Surgery be required to pass in elementary biology (Part II. of the pre-medical examination) as required of candidates for the M.R.C.S. and L.R.C.P. Not more than two terms' work in dental mechanics will be recognised before Part II. of the pre-medical examination is passed, *and no instruction in anatomy and physiology* will be recognised before the pre-medical examination has been completed—i.e., chemistry, physics and biology.—The University of Cairo, Dental Department, was added to the list of recognised Dental Schools at which the curriculum for the Licence in Dental Surgery may be taken.

Estimates for alterations and additions to the museum workrooms and laboratories were received and approved, and the architect was instructed to take steps for carrying out the work forthwith.—On the recommendation of the Library Committee it was decided to buy a new edition of the "Encyclopædia Britannica."—The annual report of the Council, to be presented to the Fellows and Members at the annual meeting on Nov. 21st, was approved.

The President reported that the Bradshaw lecture on a Review of the Surgery of the Gall-bladder and Bile-ducts would be delivered by Mr. R. P. Rowlands on Nov. 14th at 5 P.M.—The President reported that he had received from the Public Trustee *a cheque for £10,000 for the legacy* bequeathed to the College by Mrs. Eliza Macloghlin for scholarships to be founded in memory of her husband, the late Mr. E. P. P. Macloghlin, M.R.C.S. A committee was appointed for putting into operation the scheme for the award of the scholarships.—The President reported that he had received an offer from Lord Melchett of a gift of £500 a year for a period of seven years for a research scholar*ship in the College* of Surgeons, and a resolution expressing grateful appreciation of Lord Melchett's liberality was adopted.

University of London: *University College.*—A course of 40 post-graduate lectures in Biochemistry started this week and will continue throughout the session on Thursdays and Fridays at 4 P.M. Particulars may be had from the secretary of the College, Gower-street, W.C.1.

Medico-Legal Society.—A *meeting* of this Society will be held at 11, Chandos-street, Cavendish-square, W., on Thursday, Oct. 24th, at 8.30 P.M., when Lord Riddell will deliver a presidential address upon Ancient Laws and Modern Women.

The annual dinner of the Society has been fixed for Friday, Dec. 13th, at the Holborn Restaurant.

Chelsea Clinical Society.—The annual dinner will take place at the Hotel Rembrandt, Thurloe-place, London, S.W., next Tuesday, Oct. 22nd, at 8 P.M. (reception *at 7.30*). Mr. A. Rugg-Gunn and Mr. H. P. Baylis are the hon. secretaries.

Hunterian Society.—This Society has invited members of the Medico-Legal Society to attend a discussion on the Doctor and the Motorist at 9 P.M. on Monday, Nov. 18th, at the Cutlers Hall, Warwick-lane, London, E.C.

National Council for Mental Hygiene.—As we have already announced, a conference on Mental Health will be held in the Central Hall, Westminster, from Wednesday, Oct. 30th, to Saturday, Nov. 2nd. Further information may be had from the secretary of the Council at 78, Chandos House, Palmer-street, London, S.W. 1.

Guild of St. Luke.—As we announced last week the Guild's annual service will be held in Westminster Abbey on Sunday next, Oct. 20th, at 6.30 P.M. The secretary is Dr. Andrew Currie, 20, Oxford-terrace, London, W. 2.

Royal Academy of Medicine in Ireland.—At the annual meeting of the Academy on Oct. 11th it was stated that the year had been one of unusual activity, the number of Fellows on the books and the attendance at meetings having increased. The chief event of the year was the Obstetrical and Gynæcological Congress held under the auspices of the Academy. The principal officers for the ensuing session are: President, Sir William Taylor; General Secretary and Treasurer, Dr. T. P. C. Kirkpatrick; Secretary for Foreign Correspondence, Mr. W. Doolin; Presidents of Sections: Medicine, Prof. R. J. Rowlette; Surgery, Mr. R. A. Stoney; Obstetrics, Dr. A. H. Davidson; Pathology, Dr. J. Lait; State Medicine, Dr. W. D. O'Kelly.

POST-GRADUATE WORK IN GLASGOW.—A programme including weekly demonstrations, and special courses in ophthalmology, obstetrics, and diseases of the ear, nose, and throat, has been arranged for the winter session, and particulars may be had from the secretary of the Post-Graduate Medical Association at the University. Clinical assistantships are available at various institutions.

WEST HARTLEPOOL ISOLATION HOSPITAL.—After long deliberation West Hartlepool Town Council has decided to erect an isolation hospital at a cost of £12,000.

THE Surgical Instrument Manufacturers' Association held their annual dinner at the Holborn Restaurant on Oct. 11th. The chair was occupied by Mr. Patrick C. Maw, who received the guests with Mrs. Maw (senior). In accordance with custom the chairman drank wine with the members of the separate sectional committees and of the main committee. After the loyal toasts Mr. H. E. Curtis, seconded by Mr. A. W. Down, proposed the health of the Association and chairman, and Mr. Maw responded. Colonel A. Young proposed the health of the guests, and Mr. Charles E. Goulden spoke in reply.

MOTOR ACCIDENTS AT EDINBURGH.—During the year ended with Sept. 30th 448 cases of accidents caused by mechanically propelled vehicles were admitted. The cost of treatment was £3223, and the patients' aggregate stay was 7894 days.

THE FOUNDER OF HOSPITAL SATURDAY.—The Earl of Meath died in London on Friday last week at the age of 88. As Lord Brabazon he founded in 1874 the Hospital Saturday Fund, of which he was the first secretary. The amount collected in the first year was £0108; the annual collection now exceeds £100,000. Lord Meath also founded the Dublin Hospital Sunday movement.

COSHAM HOSPITAL INQUIRY.—The public inquiry, which was ordered by the Ministry of Pensions into the administration of the Ministry's hospital at Cosham, ended at Portsmouth last week. Sir Frederick Willis presided. On the last day of the inquiry evidence was given by the three chaplains to the hospital—the Rev. J. W. Watson, the Rev. A. J. Craig, and the Rev. F. E. Stainford—who described the administration as "most satisfactory," "quite good," and "most competent." Mr. C. H. Marsh, a magistrate who frequently visits the hospital, said that the patients always spoke well of their treatment, and Mr. F. Melling, the welfare officer, described the many recreational facilities enjoyed by the inmates. Sir Frederick Willis, who said that he had been much struck by the good work done in the hospital workshops, pointed out that although the coroner's jury had specifically found that there was maladministration, none of those responsible for the statements upon which that opinion was formed had come forward to substantiate them.

BRITISH EMPIRE CANCER CAMPAIGN.—In the absence of Lord Reading, Sir John Bland-Sutton presided on Oct. 14th at the quarterly meeting of the Grand Council of the Campaign. The Council renewed the grant to the Cancer Hospital for radiological research on the effect of X rays upon the blood constituents and bone-marrow. A further grant of £250 for one year was also made to Mr. E. Nevill Willmer for the continuation of his research work on the relation of the chemical nature of the media in which cultures grow to the growth of the cultures. Mr. Willmer formerly worked at the University of Manchester but has now been appointed lecturer in the Physiological Department of the University of Cambridge.

A report from the Finance Committee showed that grants made by the Campaign during the last year for research purposes amounted to approximately £25,000, whilst donations received during that period only amounted to about £17,000. The Finance Committee asked that special efforts should be made to increase donations so that the cancer research centres could be kept at their maximum activity.

The general secretary reported that details of the policy which the National Radium Commission proposed to adopt, relative to the coördination of existing bodies interested in the use of radium, had not been so far communicated to the Campaign. The Grand Council expressed a hope that early steps would be taken to bring about coördination between the work of the National Radium Commission, the use of the radium in the hands of King Edward's Hospital Fund, and the various radium centres in existence which have been formed by the Campaign.

It was reported that the North of England Council of the British Empire Cancer Campaign, combining the counties of Northumberland, Durham, Cumberland, and Westmorland, had been founded under the presidency of the Duke of Northumberland, with Sir Thomas Oliver as chairman of the executive committee.

A CONFERENCE ON WATER-SUPPLY AND POLLUTION. The British Waterworks Association is arranging conferences on Thursday, Nov. 21st, during the holding of the Public Works, Roads and Transport Congress and Exhibition at the Royal Agricultural Hall, London, N. In the morning, at 11 A.M., Mr. G. L. Pepler, chief town-planning inspector of the Ministry of Health, will read a paper on Water-supply as a Factor in Town and Regional Planning. At 3 P.M. a paper on the Purity of Drinking Waters from the Biological Aspect will be given by Dr. Wilfrid Rushton, of the Biological Department of St. Thomas's Hospital Medical School; and Dr. J. B. Firth, of the Chemistry Department, University College, Nottingham, will make some observations on river pollution.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Oct. 22nd.—5 P.M., MEDICINE. Discussion on Diseases of the Pituitary Body. To be opened by Dr. W. J. Adie. Followed by Mr. Norman Dott, Prof. E. C. Dodds, Dr. O. Leyton, Dr. Macdonald Critchley, Mr. H. W. B. Cairns, and Dr. Oljenick. Members of the Section of Comparative Medicine are specially invited to attend this meeting and take part in the discussion. 5.30 P.M., General Meeting of Fellows.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Presidential Address. Mr. Stewart R. Douglas: Some Recent Investigations into Virus Diseases.

THURSDAY.—8.30 P.M., UROLOGY. Presidential Address. Mr. Frank Jeans: Urological Statistics as a Criterion of Progress.

FRIDAY.—5 P.M., DISEASES IN CHILDREN. (Cases at 4.30 P.M.) 8 P.M., EPIDEMIOLOGY. Paper. Dr. S. P. James: Modern Aspects of the Epidemiology, Prevention and Treatment of Malaria.

MEDICO-LEGAL SOCIETY.

THURSDAY, Oct. 24th.—8.30 P.M. (at 11, Chandos-street, Cavendish-square, W.), Lord Riddell: Ancient Laws and Modern Women (Presidential Address).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

MONDAY, Oct. 21st.—5 P.M., Mr. Cecil P. G. Wakeley: Specimens Illustrating Tumours of the Brain.

FRIDAY.—5 P.M., Sir Arthur Keith: Dislocations of the Hip-joint, Congenital and Acquired.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 21st, to SATURDAY, Oct. 26th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Lecture by Mr. H. W. Carson: On Indigestion from the Surgeon's Standpoint. No fee. Tues., 8.30 P.M., Lecture by Dr. L. S. T. Burrell: Intrathoracic Tumours. Fri., 8.30 P.M., Lecture by *Dr. L. S. T. Burrell: Bronchiectasis, Abscess of Lung* and Empyema. Specially suitable for M.R.C.P. candidates.—ROYAL CHEST HOSPITAL, City-road. Tues., 2 P.M., Demonstration of Cases in Wards by Dr. Ernest Fletcher. No fee.—LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. Thurs., 2 P.M., Demonstration (general surgery) by Mr. Herbert Paterson. No fee.—THE METROPOLITAN HOSPITAL, Kingsland-road, N. Special post-graduate course in Medicine, Surgery, and Special Branches. Daily 10.30–5.30, demonstrations, operations, and lectures for two weeks.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Second week of course in gynæcology, afternoons and some mornings.—LONDON TROPICAL HOSPITAL, Gordon-street, N.W. Tues. and Thurs. afternoons, 2 P.M., Demonstrations.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Second week of course in Diseases of Children. Mornings only.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Second week of clinical course in Diseases of the Throat, Nose, and Ear. All day. Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.

MONDAY, Oct. 21st.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.

in aim and object: furtherance of the cause of science for the welfare of mankind.

Lord Riddell, also replying, expressed his anxiety at having to respond for so many societies, and had come to the conclusion that if he replied for one he would reply for all. After prolonged research he had concluded that no societies had done more to advance the cause of science, or the cause of dining and wining, than the societies represented there.

The health of the Chairman was proposed by Dr. R. L. Langdon-Down, who attributed Dr. Brackenbury's position to his loyalty to an abiding principle: that the welfare of the profession and of the public health were one and the same.

Dr. Brackenbury briefly replied.

It is proposed to hold a Primary Examination for the Fellowship at Montreal next year.—Mr. Hugh Lett was elected a member of the Committee of Management of the Conjoint Examining Board.

On the recommendation of the Board of Examiners in Dental Surgery it was decided that after July, 1930, candidates for the Licence in Dental Surgery be required to pass in elementary biology (Part II. of the pre-medical examination) as required of candidates for the M.R.C.S. and L.R.C.P. Not more than two terms' work in dental mechanics will be recognised before Part II. of the pre-medical examination is passed, and no instruction in anatomy and physiology will be recognised before the pre-medical examination has been completed—i.e., chemistry, physics and biology.—The University of Cairo, Dental Department, was added to the list of recognised Dental Schools at which the curriculum for the Licence in Dental Surgery may be taken.

Estimates for alterations and additions to the museum workrooms and laboratories were received and approved, and the architect was instructed to take steps for carrying out the work forthwith.—On the recommendation of the Library Committee it was decided to buy a new edition of the "Encyclopædia Britannica."—The annual report of the Council, to be presented to the Fellows and Members at the annual meeting on Nov. 21st, was approved.

The President reported that the Bradshaw lecture on a Review of the Surgery of the Gall-bladder and Bile-ducts would be delivered by Mr. R. P. Rowlands on Nov. 14th at 5 P.M.—The President reported that he had received from the Public Trustee a cheque for £10,000 for the legacy bequeathed to the College by Mrs. Eliza Macloghlin for scholarships to be founded in memory of her husband, the late Mr. E. P. P. Macloghlin, M.R.C.S. A committee was appointed for putting into operation the scheme for the award of the scholarships.—The President reported that he had received an offer from Lord Melchett of a gift of £500 a year for a period of seven years for a research scholarship in the College of Surgeons, and a resolution expressing grateful appreciation of Lord Melchett's liberality was adopted.

UNIVERSITY OF LONDON: *University College.*—A course of 40 post-graduate lectures in Biochemistry started this week and will continue throughout the session on Thursdays and Fridays at 4 P.M. Particulars may be had from the secretary of the College, Gower-street, W.C.1.

MEDICO-LEGAL SOCIETY.—A meeting of this Society will be held at 11, Chandos-street, Cavendish-square, W., on Thursday, Oct. 24th, at 8.30 P.M., when Lord Riddell will deliver a presidential address upon Ancient Laws and Modern Women.

The annual dinner of the Society has been fixed for Friday, Dec. 13th, at the Holborn Restaurant.

CHELSEA CLINICAL SOCIETY.—The annual dinner will take place at the Hotel Rembrandt, Thurloe-place, London, S.W., next Tuesday, Oct. 22nd, at 8 P.M. (reception at 7.30). Mr. A. Rugg-Gunn and Mr. H. P. Baylis are the hon. secretaries.

HUNTERIAN SOCIETY.—This Society has invited members of the Medico-Legal Society to attend a discussion on the Doctor and the Motorist at 9 P.M. on Monday, Nov. 18th, at the Cutlers Hall, Warwick-lane, London, E.C.

NATIONAL COUNCIL FOR MENTAL HYGIENE.—As we have already announced, a conference on Mental Health will be held in the Central Hall, Westminster, from Wednesday, Oct. 30th, to Saturday, Nov. 2nd. Further information may be had from the secretary of the Council at 78, Chandos House, Palmer-street, London, S.W. 1.

GUILD OF ST. LUKE.—As we announced last week the Guild's annual service will be held in Westminster Abbey on Sunday next, Oct. 20th, at 6.30 P.M. The secretary is Dr. Andrew Currie, 20, Oxford-terrace, London, W. 2.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—At the annual meeting of the Academy on Oct. 11th it was stated that the year had been one of unusual activity, the number of Fellows on the books and the attendance at meetings having increased. The chief event of the year was the Obstetrical and Gynæcological Congress held under the auspices of the Academy. The principal officers for the ensuing session are: President, Sir William Taylor; General Secretary and Treasurer, Dr. T. P. C. Kirkpatrick; Secretary for Foreign Correspondence, Mr. W. Doolin; Presidents of Sections: Medicine, Prof. R. J. Rowlette; Surgery, Mr. R. A. Stoney; Obstetrics, Dr. A. H. Davidson; Pathology, Dr. J. Lait; State Medicine, Dr. W. D. O'Kelly.

Manchester, Baguley Sanatorium.—Sen. Asst. M.O. £500. Also Asst. M.O. £350.

Manchester, Royal Infirmary.—Asst. M.O. for Massage and Electrical Dept. At rate of £100.

Manchester, Salford Royal Hospital.—Cas. H.S. At rate of £125.

Manor House Hospital, Golders Green, N.W.—H.S. At rate of £200.

Miller General Hospital, Greenwich-road, S.E.—Orth. H.S. At rate of £150. Hon. Surgeon. Also Hon. Physician to Skin Dept.

Plymouth City.—Asst. M.O.H. for Maternity and Child Welfare Dept. £600.

Portsmouth Dockyard and Government Civil Establishments Medical Society.—M.O.

Portsmouth Royal Hospital.—Sen. H.S. At rate of £175. Also H.P. and two H.S.'s. Each at rate of £130.

Preston and County of Lancaster Royal Infirmary.—Res. Surg. O. £300. Also H.S. At rate of £150.

Queen's Hospital for Children, Hackney-road, E.—H.P., Cas. O., and H.S. All at rate of £100. Also Clin. Asst. for Orthopædic Dept. 5s. each attendance.

Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £150.

Rotherham Hospital.—H.P. £180.

Rotherham Union Hospital, Alma-road.—Res. Asst. M.O. £125.

Royal London Ophthalmic Hospital, City-road, E.C.—Sen. H.S. £150.

Royal Naval Dental Service.—Dental Officers.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Hon. Gynæcological Reg. Also H.S. At rate of £100.

St. Helen's County Borough.—Tuber. O. £600.

St. John's Hospital, Lewisham, S.E.—Radiologist. Also Res. M.O. At rate of £100.

St. Mary's Hospital, W.—Asst. Ophth. S. Also Asst. S. for Diseases of the Ear, Nose, and Throat.

St. Peter's (Whitechapel) Hospital, Vallance-road, E.—Res. Asst. M.O. £450.

Sheffield Royal Hospital.—Res. Anæsthetist. £80.

Sheffield, South Yorkshire Mental Hospital.—M.O. £400.

Stroud General Hospital.—H.S. At rate of £125.

Torquay, Torbay Hospital.—Hon. Anæsthetist.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. Med. Reg. Also Hon. Surg. Reg.

West Bromwich, Hallam Hospital.—Res. H.S. £250.

West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Asst. Physician.

West London Hospital, Hammersmith, W.—Asst. M.O. At rate of £450. Also three Jun. Asst. M.O.'s. Each at rate of £350.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. and Jun. Non-res. H.S.'s. At rate of £150 and £100 respectively.

Wolverhampton, Royal Hospital.—H.S. At rate of £150.

Worcester General Infirmary.—Jun. Res. M.O. £120.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Southall (Middlesex) and Mevagissey (Cornwall).

Births, Marriages, and Deaths.

BIRTHS.

BLACKWELL.—On Oct. 10th, at Maison Bruges, Don-road, Jersey, the wife of Dr. A. S. Blackwell, of a daughter.

RITCHIE.—On Oct. 3rd, at Laggan, Epsom, the wife of Dr. R. H. A. Ritchie, Benhill-avenue, Sutton, Surrey, of a daughter.

WATKINS.—On Oct. 7th, at "Eskdale," King's Lynn, the wife of Dr. E. Holmes Watkins, of a daughter.

WHITLEY.—On Oct. 4th, at Thorneybrook, Chelmsford, the wife of J. T. Whitley, M.B., Ch.B., of a son.

MARRIAGES.

CRAIG—ALLEN.—On Oct. 12th, at St. James's, Birkdale, John Craig, M.D., to Mary Allen, M.B., Ch.B.

DEATHS.

BREMNER.—On Oct. 12th, at St. Giles-street, Norwich, James Morrison Gardiner Bremner, M.B., C.M. Aberd., T.D., O.B.E., Lieut.-Colonel late R.A.M.C. (T.F.), aged 63.

GAIRDNER.—On Oct. 11th, at "Sans Souci," Cheltenham, Matthew William Gairdner, M.B. Edin., aged 79.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

SOME OF LETTSOM'S CONTEMPORARIES.

Being the Presidential Address delivered to the Medical Society of London on Oct. 14th

BY DONALD ARMOUR, C.M.G., F.R.C.S. ENG.,

SENIOR SURGEON TO THE WEST LONDON HOSPITAL.

GENTLEMEN,—My first duty on taking this honourable and ancient chair of President of the Medical Society of London is to offer you my sincere thanks and appreciation for the very great honour you have put upon me. To be mentioned amongst the long list of holders of this distinguished office is, indeed a satisfaction, but one tempered by a sense of responsibility and some misgiving, lest one fall short of the high standard set by my predecessors in the past 158 years.

Our founder, John Coakley Lettsom, was born in 1744 and died in 1815. During this period of 71 years great historic events took place which had a lasting effect upon the destinies of peoples. His generation witnessed historic episodes, whose dramatic interest equalled the importance of the changes they effected in world history. As a lad of 16 Lettsom must have gloried and grieved with all England at the news of Wolfe's death and victory at Quebec, which won us Canada, and lost us one of our greatest soldiers. In those years, too, Clive was giving us India, though a less glorious death awaited him.

During the next 25 years the aspect of the world had changed. The birth of the United States of America, made possible by Wolfe's victory, had taken place. At middle age Lettsom witnessed the cataclysm of the French Revolution, and all the mighty episodes of the Napoleonic wars marked his declining years. It was an age of enlightenment, of the revolt of the intellect against tradition and prejudice. It was the golden age of benevolent despots, from Catharine II., Frederick the Great, and the noblest and least successful, Joseph II., to lesser rulers throughout Europe. It was largely owing to their efforts that the enlightened ideas were spread.

Momentous changes were taking place in almost every branch of literature and thought, so that the time of Lettsom witnessed the final emancipation of the human intellect. In no direction was this more marked than in medical thought and teaching. For, prior to this time, very little was accomplished, if we except the work of Harvey, which has withstood the test of time. Based largely on metaphysical speculation, the theories of medicine could not withstand the test of scientific proof. It was, indeed, an age of theories and system-makers. Linnaeus (1707–78), Stahl (1660–1734), Cullen (1710–90), Hoffmann (1660–1742), Erasmus Darwin (1731–1802), "the disputatious and disreputable" Brown (1735–88), as Allbutt described him, and Boerhaave (1668–1738), were all propounders of a "succession of forgotten theories." The effects produced upon medicine by these systems has been well described by Arnold Chaplin in his paraphrase from Lord Morley's "Voltaire." "For all the systems we see only dismal tracts of medical darkness, we hear only the humming of the doctors as they serve forth, to men thirsting after knowledge, the draff of a medical superstition."

But the dawn of a better day was at hand. The days of pure speculation, or of any general belief in pure speculation, were over, and in their place arose the burning desire to solve the mysteries of pathological processes. After smouldering for some 70 years the fires of progress in the sciences of Physiology, Chemistry, and Anatomy leapt again into flame, and burned with a renewed brilliancy during the period we are discussing.

The Dawn of Physiology.

Albrecht von Haller (1708–77) was the author of the first great modern treatise on physiology. Born at Berne, he graduated at Leyden, and spent 17 years at the newly established University at Göttingen, where he taught all branches of medicine, established Botanic Gardens, wrote some 13,000 scientific papers, and incidentally did some of his best experimental work. Nor were his energies limited to purely scientific work, for he stands in the first rank of our medical poets and historical novelists. In 1731 his application for the post of City Physician at Berne was rejected, with the comment, "He is a poet; why should he want to be a hospital physician?"

"His scientific work has long since passed into the impersonal stage, but to his credit stand researches of the first rank in the irritability of muscle and nerve, a demonstration of the myogenic theory of the heart's action, and an admirable and accurate account of the mechanics of the heart's action" (Osler). To read "Haller redivivus," by Kronecker, is to realise how many so-called "new" discoveries are foreshadowed in his works. Haller remains one of the outstanding figures of the eighteenth century.

Electrophysiology had its origin in Galvani's epochal discovery of animal electricity. Galvani (1737–98) was born in Bologna and began studying theology, but early turned to anatomy and physiology, became Professor of Anatomy in 1762, and practised surgery and midwifery. His wife, Lucia Galeazzi, was intimately associated with him in his great discovery. It was followed up with great skill and comprehension by Volta (1745–1825), who was Professor at Pavia. "Who," says Helmholtz, "when Galvani touched the muscles of a frog with different metals, and noticed their contraction, could have dreamt that all Europe would be traversed with wires, flashing intelligence from Madrid to St. Petersburg, *with the speed of lightning?* In the hands of Galvani, and at first, even in Volta's, electric currents were phenomena capable of exerting only the feeblest forces, and could not be detected except by the most delicate apparatus. Had they been neglected on the ground that the investigation of them promised no immediate results, we should now be ignorant of the most important and most interesting of the limits between the various forces of nature."

Physicists and Chemists.

To the physicists and chemists of the day we owe the completion of the modern theory of respiration. This was based upon the discovery and isolation of the different gases in the atmosphere—viz., carbon dioxide by Black (1757), hydrogen by Cavendish (1766), nitrogen by Rutherford (1772), oxygen by Priestley and Scheele (1771) and Lavoisier (1775). Priestley (1733–1804), confused by his adherence to the false theory of Stahl, only saw respiration as "the phlogistication of dephlogisticated air." It was left to the genius of Lavoisier (1743–1794) to reveal the true nature of the interchange of gases in the lungs, and to bury, once and for all, the phlogiston theory.

"The middle of the seventeenth century saw the profession thus far on its way—certain objective features of disease were known, the art of careful observation had been cultivated, many empirical remedies had been discovered, the coarser structure of man's body had been well worked out, and a good beginning had been made in the knowledge of how the machinery worked—nothing more. What disease really was, where it was, how it was caused, had not even begun to be discussed intelligently." The best of men had little or no appreciation of the importance of the study of the changes wrought in the body by disease. Sydenham scoffed at the value of post mortems. The first time that anatomical knowledge was systematically applied to the service of medicine was in the great work, "de Sedibus et Causis Morborum per Anatomen indagatis," published in his seventy-ninth year by Giovanni Battista Morgagni (1682–1771). It was the foundation of modern pathological anatomy, or, as Virchow said, the introduction of the "anatomical concept" into medical practice It was the first time that the records of post-mortem findings were correlated with clinical records to any large extent. This work, "one of the great books in our literature" (Osler) was translated into English by Benjamin Alexander in 1769, and had a very great influence upon the development of medical science.

Another publication, contemporary with that of Morgagni, should be mentioned, having as it did a profound influence upon the clinical medicine of the future. Leopold Auenbrugger was born at Gratz, in Styria, on Nov. 19th, 1722. Though the son of an inn-keeper, he received a University education, and his medical training was obtained under Van Swieten, a great authority of that time. In 1751, at the age of 29, Auenbrugger was appointed physician to the Spanish Military Hospital in Vienna. After seven years' observation and testing of his method he published, in 1761, his epoch-making volume, entitled, "Inventum novum ex percussione thoracis humani, ut signo, abstrusos interni pectoris morbos detegendi." The new method was, however, practically unrecognised by the clinicians of his time. It was left to Corvisart, physician to Napoleon and leader of medical thought in France, to obtain for Auenbrugger's work its proper recognition. This was 47 years after its first appearance in Germany, and just one year before Auenbrugger died in 1809.

Morgagni's influence upon medicine was further strengthened and increased by the work of Bichat (1771–1802), who in his all too short life of 31 years, some of it spent as a surgeon in the French Revolutionary Army, showed himself a master-worker in scientific medicine and anatomy. His "Traité d'anatomie descriptive" in five volumes, and his "Anatomie générale, appliquée à la Physiologie et à la Médicine," entitle him to be called the creator of descriptive anatomy, and opened out an entirely new field for anatomists. Like Hunter, he regarded disease as an alteration of vital properties or principles. That in his "Physiological Researches upon Life and Death" he adhered to an obsolete belief, which he summed up in his famous definition of life as "the sum of the forces that resist death," does not detract from his great scientific attainments. His studies laid the foundation of modern histology.

Morbid Anatomy and Matthew Baillie.

It was in this country that the coping-stone was placed upon this building up of the science of morbid anatomy. Matthew Baillie (1761–1823), a nephew of the Hunters, published in 1793 his work, "The Morbid Anatomy of some of the Most Important Parts of the Human Body." It was the first book in English on the subject, and the first in which morbid anatomy was treated as a subject by itself. Baillie has been called the "father of medical pathology." Morgagni's work, which may be regarded as the foundation of the study of diseased structures and organs, is long, intricate, and difficult of reference. Baillie's work, illustrated by William Clift, is characterised by its conciseness and its accuracy of observation.

A contemporary estimate of his work shows how warmly it was received on its appearance. "Though former writers had treated this subject (morbid anatomy) in innumerable volumes, it was to be regretted that before Dr. Baillie's time there was no regular system or method of arrangement pursued by them which could render this study useful. Dr. Baillie, by a nice and accurate solution of the morbid appearances of every part of the body, and the peculiar symptoms which in life distinguish them, placed in a narrow and clear compass an extensive and valuable mass of information, before his time contemptible." It exerted a profound influence upon medical teaching, not only in this country, but abroad as well.

These, then, were the contemporaries of Lettsom, who did most to influence the development of medicine in his day. Others there were, though of less renown, who worked quietly in their modest way to advance some particular branch of our profession.

Hewson (1739–74), an almost forgotten English physiologist, first a pupil of the Hunters, then a partner at the school in Great Windmill-street, was awarded the Copley Medal for his work on the lymphatics, while modern research has confirmed his views upon coagulation of the blood. Knowledge of the physiology of digestion was advanced by the work of de Réaumur (1683–1757), and confirmed by Spallanzani; while Cruikshank, the Physician of Dr. Johnson in his last illness, and Whytt, both of Edinburgh, were pioneers in the physiology and pathology of the nervous system.

William Withering (1741–99), a Shropshire graduate of Edinburgh University, was one of the ablest clinicians of his time, and one of the greatest medical botanists, hence his title, "the flower of physicians." He was a pioneer in the correct use of digitalis. He had learned from an old Shropshire woman that foxglove was good for dropsy, and then began trying it in heart disease, and recommending its use wherever he could. In this he was firmly opposed by Lettsom, who, in that day, enjoyed the largest and most remunerative practice in London. Lettsom, on the recommendation of Withering, had prescribed digitalis in eight cases, all of which terminated fatally. Its use had led to the fatal result of the last illness of Charles James Fox. Lettsom published his cases, and warned the profession against the use of the drug.

William Heberden (1710–1801), whom Johnson styled "Ultimus Romanorum," the last of our great physicians, is remembered by his descriptions of varicella, angina pectoris, and the nodules of arthritis deformans. His *Commentaries*, as Dyce Duckworth has pointed out, are rich in clinical minutiæ.

John Fothergill (1721–80), a Quaker, pupil of Monro primus, and friend of Lettsom, is commemorated in this Society by the medal which bears his name. He was employed by Monro in revising his work on Osteology, and he was the first graduate of Edinburgh University to be admitted to the Royal College of Physicians of London. His "Account of the sore-throat attended with ulcers" ranks as a classic amongst the descriptions of diphtheria, and he was the first to describe the condition we know now as tic douloureux. He established at Upton, in Essex, the finest botanical garden to be found in Europe at that time. Having family connexions and many friends in America, it was only natural that he showed great sympathy for the American colonies, advocated the repeal of the Stamp Act, and was associated with Benjamin Franklin in a plan for reconciliation with the Mother-country. Of him Franklin said, "I can hardly conceive that a better man has ever existed." And J. F. Payne defines his place in the profession in the following words: "He will always remain an important representative of the naturalistic and anti-scholastic tendencies of English medicine in the latter half of the 18th century."

Towards the end of the century came one of the greatest triumphs in preventive medicine, the introduction of vaccination by Edward Jenner (1749–1823). The life and work of this friend and pupil of John Hunter's are, like the latter's, too well known to us all to need recapitulation here.

Our next President, John Whitehead, had a varied career. He was born in Cheshire about 1740, of humble parentage. Early in life he was converted by a Methodist preacher and joined the Wesley movement. After acting as a lay preacher at Bristol he married and set up as a linen draper. Removing to London, he joined the Society of Friends, and conducted a large boarding-school at Wandsworth. Then Barclay, the brewer, offered him a life annuity of £100 to travel with his son on the Continent. He accepted, and on reaching Leyden he entered as a medical student in 1779, and graduated M.D. in 1780. On returning to London he became, through Lettsom's influence, physician to the London Dispensary. In 1784, the Society of Friends pushed his candidature for the post of physician to the London Hospital, but his election was declared invalid owing to some slight irregularity. He left the Society of Friends and again became a Methodist. He was Wesley's medical adviser and preached his funeral sermon. He died at Fountain Court, Old Bethlem, in 1804.

Of our eighth President, John Relph, I can tell you little. He was a native of Cumberland and entered Leyden in 1778, graduating M.D. the same year. He was made a Licentiate of the Royal College of Physicians in 1784 and elected a physician to Guy's Hospital in 1789. He died in Mark Lane in 1804.

The form and features of our ninth President, James Sims, are familiar to us all, sitting, with a cocked hat upon his head, in the Presidential Chair, as painted by Medley in the picture of our founders. He is described by a contemporary surgeon (Wadd) as "a good-humoured pleasant man, full of anecdote, an ample reservoir of good things, and for figures and facts a perfect chronicle of other times." Needless, after this, to say he was an Irishman, born in Co. Down in 1741. He took his M.D. at Leyden in 1764 and practised for a time in Tyrone. On removing to London he received very great assistance from Lettsom, and soon acquired a lucrative practice. He served this Society as President for 22 consecutive years, being finally displaced only by the strenuous exertions of the younger Fellows. The revolt was led by Marcet, physician to Guy's, and Yelloly, physician to the London Hospital. A contemporary account of the secession, which resulted in the formation, in 1805, of the Medical and Chirurgical Society, is not without interest, even though not perhaps pleasing to our amour propre. "This Society (The Medical Society), like many others, has become, from the increasing extent of the profession, too numerous in its members, and it has been alleged not so select at all times. From this cause, dissensions arose, but as good, at times, issues from apparent evil, it gave rise to the Medical and Chirurgical Society, a most elevated establishment, and which was formed purposely with a view to exclude the lower orders of the profession.". And then follows the sop to Cerebus. "*As the Medical Society, however, is the* original parent of whatever future institutions may arise for medical improvement, so the founders of it may be said to have deserved well of the profession in general, as first, by their exertions, influence and talents, having set the machine in motion." In 1802 Sims made over his valuable collection of books to this Society, in consideration of an annuity of £30 a year to be paid to himself and his wife, and of £45 annually to the survivor. He retired to Bath a rich man and died there in 1820.

The eleventh President of this Society, George Pinckard, is the first to have served with the Forces of the Crown on active service. Born in 1768 he studied medicine at the then united Hospital of St. Thomas's and Guy's, then at Edinburgh, finally graduating at Leyden in 1792. In 1795 he was appointed physician to the Forces, and in that capacity accompanied Sir Ralph Abercromby's expedition to the West Indies. In 1798 he was in Ireland, and served in the rebellion of that year on the staff of General Hulse. For these services he was promoted to the rank of Deputy Inspector General of Hospitals, and was jointly responsible for the direction of the Medical Department of the Army in the Duke of York's expedition to the Helder. He founded the Bloomsbury Dispensary, and was physician to it for 30 years. He died with tragic suddenness from angina pectoris while examining a patient in his consulting room.

Joseph Adams occupied the Presidential Chair in the year of Lettsom's death. He was the son of an apothecary in Basinghall-street, and attended lectures under Pott at St. Bartholomew's, Saunders at Guy's, and John Hunter at St. George's. He took his degree at Aberdeen in 1796. He is chiefly known as a warm admirer and defender of John Hunter, and published in 1816 "Memoirs of the Life and Doctrines of the late John Hunter, Esq."

These, then, are some of Lettsom's contemporaries. Each in his way has had some part in moulding our practice of to-day. Anatole France says "It is the greatest of frivolities to waste time in cemeteries." But surely the contemplation of the lives and the study of the works of those who have gone before and left an indelible mark upon our profession in the past, are things that none of us can despise. For, as Andrew Lang has said, "The little present must not be allowed wholly to elbow the great past out of view."

A CHILD WELFARE FILM.

A PROPAGANDA film with the title "H.M. the Baby," produced for the Mutual Property Insurance Company by Community Interest Films, Ltd., was shown at the American Theatre, Wardour-street, on Oct. 12th. The story deals with the marriage of a young couple, in spite of opposition by the girl's father, who refuses to receive her or her husband. The young mother attends an antenatal clinic and goes for her confinement to a maternity home, the scenes for this part being staged at Queen Mary's Maternity Home, Hampstead. Eventually the father is reconciled when his grandson, under the guidance of health visitor and infant welfare centre, wins the first prize at a baby show. The film is approved by the Central Council for Health Education, and the intention is to lend it to medical officers of health and other authorities interested in health education.

A NON-PAYING PATIENT.

To the Editor of THE LANCET.

SIR,—For the benefit of my colleagues, both in consulting and general practice, I should like to call attention to the fact that there is abroad in London an individual, whose signs and symptoms are interesting enough to engage attention, but whose bank account is non-existent. She is about 40, short, plump, dark, blue eyes, slight moustache, and the history is one of radical mastoids and a severe intracranial operation on the right side. The signs bear this out, showing, in *addition, an hysterical hemiparesis and* hemianæsthesia on the right side. Unless they felt repaid by the interest in an amusing case, medical people would be wise not to waste their time or risk their money over her.

I am, Sir, yours faithfully,

Edgware-road, W. Oct. 9th, 1929. H. I. DAVIES.

ADHESIVE BANDAGES AND DRESSINGS.

Messrs. T. J. Smith and Nephew, Ltd., Neptune-street, Hull, and London, Glasgow, and Manchester, have called our attention to "Elastoplast" adhesive dressings and bandages, whose chief feature is that they are easily moulded to the shape of the surface to which they are applied, and that they are non-irritant. The fabric base of "elastoplast" is so woven that it stretches in any direction and the material is available in sizes suitable for various purposes, such as the treatment of varicose veins, the replacement of splints when less rigidity is required, and the dressing of fingers, eyes, and boils. From the fabric, sold in spools, dressings may be cut to meet any emergency. It is obtainable in two styles: in "A" one side is entirely covered with adhesive which allows the patient to take a bath without removing the dressing; in "B" the material is covered with adhesive in strips so as to allow of ventilation. Elastoplast makes a convenient and time-saving addition to the resources of the surgery.

MEDICAL GOLFING SOCIETY.—The autumn meeting of this Society was held at Deal in the Royal Cinque Ports Golf Course on Oct. 12th and 13th, and was attended by over 70 members. The weather was delightful and the course in admirable order. The Selling Sweep Dinner was held at the South-Eastern Hotel where nearly all the members stayed. The competition results were as follows: Singles *v.* Bogey won by Claud Apperley, 2 up, after a fourfold tie with Sir Milsom Rees, G. F. Wilson, and J. Pringle: Foursomes *v.* Bogey won by J. Pringle and J. Collins, all square; and Canny Ryall Cup won by C. V. Mackay (84 – 12 = 72), A. Galletly (76), D. A. Davies and C. Max Page (77).

TRAINING OF MIDWIVES.—In the course of a published statement on the report of the Departmental Committee on the Training of Midwives (see THE LANCET, Sept. 28th, pp. 669 and 680), the Council of the Midwives' Institute says that it "views with surprise and strong disapproval the suggestion that the control of the training and curriculum for the profession should be taken over by a Government department, thus eliminating the principle of self-government and self-development from a professional point of view that is accorded to all other professions. And considers that the withdrawal of control from a specialised body on which organised midwives have definite representation and powers would lower the standard of the profession and lessen its *attraction for the most suitable* women to undertake the serious and responsible part in the struggle against maternal mortality assigned to midwives by the Departmental Committee."

An Address

ON THE

FUTURE OF OBSTETRICAL PRACTICE.

Being the Presidential Address delivered before the Obstetrical Section of the Third Australasian Medical Congress, at Sydney on Sept. 5th, 1929,

BY HENRY JELLETT, M.D. DUB.,
F.R.C.P. IREL.,

PRESIDENT OF THE SECTION; CONSULTING OBSTETRICIAN TO THE HEALTH DEPARTMENT OF NEW ZEALAND; FORMERLY MASTER OF THE ROTUNDA HOSPITAL.

THE art of midwifery has passed through many stages. Originally it may be assumed that women delivered themselves of their children, as do wild animals, and with as little danger to themselves. Gradually, occasional difficulties introduced themselves, and in response to them elementary methods of assistance were devised. Difficulties increased, and methods of assistance became more developed. Greater use was made of the methods evolved, and, as a result, new difficulties and dangers appeared. Human life became more complicated, its relations more crowded and artificial, and pre-existing disease became more common. The mechanical complications of labour became greater and the need for assistance more frequent. To the ordinary risks were added risks of blood infections brought by those whose object was to assist, with the probable result that efforts, made to reduce *the risk of labour, instead* multiplied that risk. There can be little doubt that maternal mortality before the time of Semmelweiss was considerably greater than it would have been if every woman had been left unaided. There is even a certain element of possibility that, in the case of the healthy woman, this is still so. In the past interference during labour was limited, and asepsis was unknown. In the present, interference is frequent and asepsis is occasional. In the future, if the rate of maternal mortality is to be brought to the minimum, it will be necessary to reverse this relationship. Interference must so far as possible be avoided, and asepsis must be positive.

THE ESSENTIAL AIMS OF MIDWIFERY.

The art of midwifery has been devised with three aims before it, and it is being slowly perfected. The first is to bring a mother safely through a normal pregnancy, labour, and puerperium. The second is to ensure the delivery of a healthy infant. The third is to leave the mother in as normal a *condition* at the end of the puerperium as she was at the beginning of the pregnancy. Similarly, there are three basic essentials on which this art is built—knowledge, skill, and suitable environment. Knowledge is necessary to avoid both complications and interference, and to treat the one and to regulate the other should it become inevitable. Skill is necessary to obtain the fruits of knowledge. Suitable environment, by which I mean the circumstances under which a labour takes place, is necessary in order that the normal and abnormal events of labour may be conducted in an orderly and aseptic manner.

If these three essentials can be obtained, then the risks of childbirth will be reduced to their lowest. If they are absent, or if the possession of a due share of one is allowed to count as an equivalent to the absence of another, then the whole structure falls. Under such circumstances, as I have already suggested, it is quite possible that, so far as the rate of mortality is concerned, humanity as a whole would be just as well off without it, although individuals might still benefit.

Are these essentials obtainable? I think they are, at any rate to a much greater extent than is the case at present. But, before we shall get them, it will be necessary to throw aside a number of hampering ideas. The position of midwifery in the curriculum of the student, if judged by after consequences, is not and cannot remain inferior to that of medicine or surgery. Even if in the past the medical quack ranked before the surgical barber, and both before the "midwife"—male or female, the fact remains that to-day the badly taught "midwife" can kill more than the highly educated physician can cure, and that a good working knowledge of the art of surgery does not always make the surgeon more successful. If actual results are to be the criterion of relative importance, then I venture to suggest that the results of the obstetrical art, properly practised, *are at least as important, though less brilliant, than* those of medicine and surgery.

Then there is the public ignorance of the essentials of midwifery—an ignorance which takes many forms. There is one form which places the presence of a medical practitioner and prompt action before everything else, and which drives the practitioner into acts repellant to him. There is another form which decries the efforts of the practitioner to obtain an environment that will make asepsis possible, and which grudges the small incidental expense necessary. There is another form which considers that a medical practitioner is well paid for his skill, his time, and his assistance during pregnancy and labour, by a fee far lower than would be paid for a minor operation of general surgery.

It is popular to speak and to write as if medical science sprang yearly from one step to another, and that each step formed a permanent and desirable advance towards the top storey of knowledge. This may be so in medicine, but it is not the case in the art of *midwifery*. *It is now just 30 years since the first* edition of my small midwifery was published. It contained the teachings of Sir William Smyly. It contained the statistics of the Rotunda Hospital during his and during the first year of Dr. Purefoy's Masterships. It is of interest to note their treatment of the major complications of pregnancy and labour—sepsis, hæmorrhages, eclampsia—and to examine their results.

The aseptic technique of Sir William Smyly was far ahead of that of the average private hospital of the present day. The treatment of puerperal infection was no more unsatisfactory. The treatment of the hæmorrhages of pregnancy and labour was practically identical with that which is now generally accepted, although at the time students were threatened with rejection at their examination if they mentioned it! The treatment of eclampsia had not been placed on the firm basis on which Tweedy and Stroganoff have since placed it, but it was superior to that too often adopted to-day in private practice.

As for the general results, the following figures will show them. During the five years ending 1898, 7008 women were confined in the hospital. The total mortality was 22—that is, at the rate of 3·1 per 1000, including abortions.

Candidly, if we exclude the recognition of the necessity for a more rigid aseptic technique, I do not know of any very marked advance since the time to which I allude except the introduction of antenatal care. We seem to run after methods—principally operative methods, and to neglect men—and women. We are eternally looking for new advances—advances that must be built on knowledge, and neglecting the foundation on which that knowledge must be built. We create hospitals which make interference with normal labour easy, and we neglect the essentials which make interference safe, and the teaching which makes it unnecessary. We make medical practitioners and midwives, but we fail to provide them with a sufficient knowledge of midwifery. If it is true that in countries other than the British Empire, and even in some parts of the British Empire, the recognition of correct *principles and practices has solved the question* at which we stumble, then let us not rest content until they have become the principles and practices of the British Empire. The present system of caring for the pregnant and the lying-in woman is essentially wrong; I propose to show that by the adoption of a different system it is possible roughly to halve the present rate of maternal mortality.

CARDINAL FACTORS IN CONTROL OF MORTALITY.

I wish to draw your attention to certain factors in the management of maternity, the connexion of which with maternal mortality is so obvious that I think it is permissible to regard them as the cardinal factors which control the rate of that mortality. The first of these is the nature of what, for the sake of convenience, I shall call the midwifery attendant, that is, the person who is directly responsible, either in part or in whole, for the care of the pregnant and lying-in woman. The second is the skill and knowledge possessed by that attendant. The third is the degree of antenatal care and antenatal diagnosis which each woman receives. The fourth is her environment during labour.

If we could go back several centuries and examine the history of maternity at that time we should probably find that none of these things received any practical attention or even recognition. Further, we should probably find that while the mortality accompanying normal pregnancy and labour was very low, the mortality accompanying abnormal pregnancy and labour was very high. If, however, we go back only 50 years or so and again examine we shall find that, while some importance was attached to the nature of the midwifery attendant and to the degree of skill and knowledge possessed by him, little attention was paid to antenatal care or to the environment of the patient. The maternal mortality of the period was probably far higher in the case of the normal woman than it has been several centuries before, while in the case of the abnormal woman it was certainly far less. Finally, if we take the present time, we shall find that, while full recognition is given in theory to all four factors, in practice they are either erroneously interpreted or overlooked, and that the resulting mortality in both types of case is probably very similar to what it was 50 years before. In fact, I am afraid that an unprejudiced investigator, with all the facts before him, would be driven to the conclusion that the basis of modern midwifery practice was as unstable as it had ever been, and that the edifice reared on it was so shaky as to be unsafe.

The Present System of Maternal Care.

What is this edifice? Broadly I may put it something like this. A woman discovers she is pregnant. She discusses the matter with her friends, who advise her to do diverse things. After an interval of some months she interviews a medical practitioner and engages him for her confinement. It is the only part of the whole procedure with which she thinks he is concerned. He writes down her name and the probable date of her confinement. He perhaps recommends a nurse, only to find that she has already engaged one. Patient and doctor mutually forget each other's existence until about the onset of the second stage of labour, or, in a primipara, perhaps later. The doctor is then summoned. If immediate delivery is not imminent, he is expected to produce it by the usual means, and often does so. He visits the patient during the puerperium and then leaves her. Finally, he is paid a fee which, while it may have some relation to the services rendered, has no relation whatever to services which ought to have been rendered.

There are a few more details to be added. The education of the practitioner in obstetrical matters may have been sound and thorough. On the other hand, it is likely to have been so cramped by the exigencies of the other parts of his medical curriculum as to bear no relation to the responsibilities he has got to discharge. Similarly, the education of the nurse may have been sufficient. On the other hand, it may have been so incomplete as to make it unsafe to trust her even with the sterilisation of the practitioner's instruments. The environment of the patient during labour, by which I mean the various conditions which render the carrying out of asepsis and the prompt treatment of obstetrical emergencies possible or impossible, may be as good as those surrounding a minor surgical operation, or so bad that no one with a surgical conscience would care to attempt one.

Everyone—patient, relations, nurse, and doctor—may be in haste, and the chance of a normal labour reaching a normal termination be very small. Further, the practitioner, through no fault of his, may have been obliged to come directly to his patient from a case of a septic nature. The puerperium follows, and the patient lies in bed for perhaps 8, 10, 14 days, or even for longer. Her active movements are often discouraged, and the idea of her leaving bed is sometimes viewed with horror. Finally, there is no effective postnatal examination or care.

Is my description exaggerated? Let me put the matter in the form of question and answer.

What is the chief essential in the management of normal pregnancy and in the prevention of abnormal pregnancy?—I answer—antenatal care.

What are the chief essentials in the management of normal labour?—Absence of haste and asepsis.

What is the chief essential in the prevention of abnormal labour?—Antenatal diagnosis.

What are the chief essentials in the treatment of abnormal labour?—Asepsis and operative facilities.

Are these essentials usually present in the average case of maternity as conducted in the present time?—I do not think they are.

Hence my opinion that the cardinal factors which control maternal mortality are erroneously interpreted, and that, this being so, the present system of caring for the puerperal woman is wrong.

A Comparison of Results.

I want to bring to your notice certain statistics which show the relative rates of maternal mortality in different parts of the world, and in one section of these parts. In each case the figures cover a period of six years ending 1927.

Countries.	Number of live births.	Total deaths.	Death-rate per 1000 live births.
Great Britain, Ireland, Australia, New Zealand	6,060,532	26,506	4·22
Australia	676,599	3,522	5·21
New Zealand	169,494	821	4·87
Holland and the Scandinavian countries ..	2,064,620	5,220	2·53
Holland alone	1,081,096	2,809	2·59
Queen Victoria's Jubilee Institute •	317,758 (labour)	524	1·41

It will be seen at a glance that these figures fall into two groups. There is first a group in which the death-rate is relatively high, and which includes both all that area of the British Empire which I am considering, and also its component parts. Secondly, there is a group in which the death-rate is markedly lower. It includes Holland and the Scandinavian countries. As a connecting link between the two, and as a proof that the cause of the difference is not racial, I add the statistics of a sub-group of the British Empire, which shows a very low mortality. If the views I have expressed above are correct, we should find that the practice of obstetrics in Holland and the Scandinavian countries rests on a wholly different basis to that on which it rests in the British Empire.

ANALYSIS OF THE FOUR FACTORS.

I now propose to analyse the differences which exist between the two groups in respect of the four cardinal factors that control maternal mortality.

1. *The Nature of the Midwifery Attendant.*

I think I am right in saying that, in the British Empire, as I have limited it, the majority of women are attended in labour by medical practitioners. In Holland and the Scandinavian countries, and under the care of the Queen Victoria's Jubilee Institute, all normal cases of labour are attended by midwives. Here, then, is a very marked difference. Is it a vital one? Personally I think that it is, and I will go into my reasons for so thinking. There are three types of midwifery attendant to whom the care of the normal lying-in woman can be entrusted—the obstetrical specialist, the general practitioner, and the midwife. If I am right in thinking that the chief essentials of the management of normal labour are asepsis and the avoidance of interference, the specialists and the midwife are in a better position than is the general practitioner. Both can give, or ought to be able to give, the necessary time and need not to be driven by the exigencies of general practice to shorten the labour to the injury of the patient. For the midwife it is, or ought to be, a matter of one patient at a time. For the specialist his fee is, or ought to be, sufficient to enable him to give all the time that is wanted.

The position of the general practitioner is different. In the day-time the demands of general practice press on him, as well as those of midwifery. At night he must get some sleep if he is to carry out his work. The natural and practically *unavoidable result is that* he comes to a case of midwifery in a hurry, and that the two essentials of midwifery—asepsis and the avoidance of interference—are crowded out. Again, he is in constant contact with infection of different kinds, and no matter how carefully he may try to remove its effects it is not always possible for him to do so. If the specialist comes into contact with infection in the course of gynæcological practice he can find a substitute to replace him temporarily. The specialist, however, we may put aside. The real issue is between the general practitioner and the midwife, and the *midwife has neither the need nor the right to come* into contact with outside infection, nor having done so, to attend another patient until she is again safe. The septic death-rate amongst over 300,000 patients of the Queen Victoria's Jubilee Institute was 0·33 per 1000, and in Holland it was 0·77 per 1000. During the same period in England and Wales it was 1·40 per 1000. In Australia it was 1·7. In Ireland it was 1·79. In New Zealand and in Scotland it was 1·82. That is to say, the septic death-rate amongst women mostly attended by the medical profession was from something more than four to something less than six *times greater than* amongst women attended wholly by nurses. This being so, it would seem to be apparent that on the grounds of freedom from sepsis alone the care of the normal woman by the midwife, as opposed to the practitioner, is clearly indicated. Further, it is obvious that the other dangers of pregnancy and of normal labour are not increased thereby, seeing that in Holland they account for 1·82 of the total mortality, and amongst the patients of the Queen Victoria's Jubilee Institute for 1·07, while in England and Wales they account for 2·5, and in Australia for 3·51.

Here, then, is a very marked difference between low mortality and high mortality countries in regard to my first cardinal factor—the nature of the medical attendant. Accordingly, I am going to suggest that the midwife is the proper person to conduct normal labours. To support this suggestion I give from the point of view of the patient the statistics I have already quoted. From the point of view of the medical profession I advance the further suggestion that, to comply with the legitimate demands of present-day midwifery and to accept its customary remuneration, means that the medical practitioner must be a philanthropist—not by wish but by compulsion, and not on occasions but all the time. Whether such an occupation is compatible with the financial and domestic necessities of a professional individual is for each individual to answer for himself. My own view is that, when the time comes that all normal cases are handed over to midwives, the medical practitioner will wonder how he stood for so long a servitude under which his night was converted into day, his work into toil, and his obste[illegible] into a nightmare.

2. *The Degree of Skill and Knowledge Possessed by the Attendant.*

Here, again, we find the most striking differences between the practice of the British Empire and of Holland in regard to the education of both the student and the midwife. I will select for contrast the training of the medical student which prevailed at Otago University, New Zealand, up to the end of 1927 and the similar training at Utrecht University. In each case the total length of the medical course is six years.

In the *Otago* University the course is as follows:—Fifth year: Attendance on a course of 50 theoretical lectures. Fifth and sixth years: Attendance on at least 20 midwifery cases, of which at least four shall have been attended under proper supervision at a maternity hospital. Twelve attendances at the antenatal clinic. Attendance at the University Maternity Hospital, which has 10 beds, when called on for practical instruction in cases of difficult labour. Each student attends approximately six abnormal labours. Attendance on 12 clinical lectures delivered by the University tutor.

In the *Utrecht* University the course is as follows:—Second year: Two hours weekly of theoretical instruction in midwifery and demonstrations on the phantom. Third year: Three hours weekly of similar instruction. Fourth year: Ten hours weekly of similar instruction. The student then passes an examination in theoretical midwifery. Fifth and sixth years the work is as follows: Eight hours weekly of special instruction in practical obstetrics. Six-week dressership in the University Midwifery Hospital, of which two are spent in residence. One month as extern accoucheur working on the district. The standard of practical work is 50 antenatal examinations and 40 conductions (not attendances).

In the training of midwives a similar difference is apparent though it is not so marked. In New Zealand the course for women without general training is 10 months. In Holland it is three years. I select New Zealand for comparison because the facts are before me, and not because it serves to emphasise the differences. As a matter of fact its course for medical students was at that time, and probably still is, inferior to the corresponding course in Great Britain, owing to circumstances which are at present difficult to control. On the other hand, its training of midwives is considerably better than the average training of midwives as laid down by the Central Midwives Board of England and Wales. A similar remark applies to the nurses of the Queen Victoria's Jubilee Institute who, so far as I understand, have all received a general training and who have received their midwifery training in recognised maternity hospitals.

The essential duties of the medical practitioner in maternity work are to be found in the prevention and treatment of obstetrical disease and anomaly. If his education does not fit him to discharge them, then his services towards the prevention of maternal mortality are very small. Further, if the management of normal cases is to be given to midwives, it is obvious that the present system which prevails in Great Britain, whereby one midwife can be almost wholly trained by another midwife, must become a thing of the past, and that even the more advanced training given in New Zealand is not sufficient.

3. *Antenatal Care and Diagnosis.*

This, again, is a factor of vital importance, and one which in regard to antenatal care is partly, and in regard to antenatal diagnosis is wholly, an essential duty of the medical profession. To emphasise this importance in the case of antenatal care it is only necessary to refer to its effect on the incidence of eclampsia. The patients of the Queen Victoria's Jubilee Institute receive antenatal care, and the mortality of eclampsia amongst them was 0·10 per 1000 deliveries. In New Zealand during the same period the mortality was 1·10 per 1000 live births.

Statistics of the work of a maternity hospital collected by Ray and laid before a Conference on Maternal Mortality and Morbidity in 1928 show that, before antenatal work was systematised, there were ten deaths from eclampsia amongst 10,505 patients. After it was systematised there was one death from eclampsia amongst 13,067 patients. At the East End Maternity Home amongst 4173 patients there was not a single case of eclampsia. On the other hand, the attendances at the antenatal clinic numbered 11,881.

The only positive figures which I can place before you to show the effect of antenatal diagnosis on the prevention and prognosis of difficult labour are as follows. In England and Wales the death-rate from the "other accidents of labour" and from hæmorrhage was in the statistics from which I have already quoted 0·96 per 1000 live births, in Australia it was 1·22, in New Zealand it was 0·98. The corresponding death-rate amongst the patients of the Queen Victoria's Jubilee Institute was 0·33 per 1000 labours. That is to say, it was approximately a third of that of England and Wales and of New Zealand, and slightly more than a fourth that of Australia. I think that if you will recall the appalling consequences of undiagnosed and improperly treated contracted pelvis and particularly of the minor degrees of contraction, with its sequelæ failed forceps, failed craniotomy, delayed Cæsarean section, and septic infection, you will be able to estimate the effect of careful antenatal diagnosis yourself.

I have already suggested that the medical profession should give up the care of normal labour to midwives. I now suggest that they should replace this irksome and in every sense of the word unprofitable task by careful antenatal care and diagnosis, effective assistance in abnormal labour, and sufficient postnatal care. I quite recognise that many practitioners are trying and have tried for some years to give such care, in spite of the fact that the considerably increased demand it makes on their time goes unrewarded. Still the fact remains that, whereas in Holland every mother comes under the care of a medical practitioner during labour, in the British Empire it is only the minority who do so. Antenatal care and diagnosis is capable of removing almost completely the graver dangers of eclampsia and of obstructed labour by preventing the occurrence of the one and by the anticipation of the other. If it did nothing more than this it would probably reduce the maternal mortality-rate by something between 1 and 1·5 per 1000 births.

4. *Suitable Environment.*

I have explained what I intend to convey by this term—namely, everything which tends to promote the practice of asepsis, and which makes necessary intervention in obstetrical emergencies easily accomplished. I have no means of judging whether the environment of labour is better in Holland than in the British Empire, and so I will assume that it is the sole cardinal factor in which the practice of the two countries does not materially differ. Still its importance is such that I must discuss it. The value of suitable environment varies theoretically according to the circumstances and nature of the case. Thus, in a normal confinement normally managed in a private house, environment is possibly of small importance. Intervention is, and even vaginal examination may be, unnecessary. Consequently the risk of infection is small. In hospitals, public or private, environment is all-important on account of the increased risk of infection due to the presence of other patients. In abnormal cases, whether in private houses or in hospitals, environment is again all-important. So much in theory is probably right. In practice, however, seeing that unexpected complications may occur and necessitate intervention, suitable environment is always necessary.

The details of a suitable environment are all-important, but it is impossible to do more than touch on them. The aseptic environment must be such as to enable the labour to be carried out with the same degree of asepsis as is a surgical operation. It is strange that the truth of the fact is still unrecognised, and even contested, by so many people, and that it is possible to find a medical man removing tonsils in the morning with the strictest aseptic ritual and a placenta in the evening with none. Yet the removal of a placenta is possibly the operation most fraught with septic possibilities of any in the whole field of medicine. I am sure that the defence to this will be that the surroundings of an average case of labour make asepsis impossible. My reply is that we, as a profession, have had some 50 years at least in which to teach nurses and the public that these surroundings must be changed, and that we have not done so. Even at the present time, when a technique, which makes asepsis possible amidst bad surroundings, has been worked out in a satisfactory manner, medical practitioners are to be found who decry it as a useless and unnecessary expense and complication. Consequently environment does not improve, and the responsibility rests with us.

A very similar remark may be made regarding the environment which makes the treatment of obstetrical emergencies easy and safe. How many practitioners insist that the patient's room shall be so arranged that if, for example, postpartum hæmorrhage should occur, its treatment can be immediate and effective? I am almost afraid to ask the next question. How many practitioners carry with them the necessary appliances for its treatment, and prepare them beforehand so that they may be ready for an emergency? And yet the sole excuse for the presence of a medical practitioner during normal labour is that he is available for the treatment of the unforseen complication. Otherwise he is only an additional source of danger.

Again, the environment in private maternity hospitals is often no better than in a private home. And yet it is generally recognised that such hospitals are a danger rather than a benefit unless improved asepsis and general facilities more than compensate for the increased danger caused by the aggregation of patients.

CIRCUMSTANCES HAVE MADE LABOUR PATHOLOGICAL.

Someone may suggest, as has been so often suggested before, that it is absurd to worry about environment, and to treat as pathological what is a normal physiological function. This is a confusion of ideas, and one which in the past has helped to increase maternal mortality. It is true that the process of labour under normal circumstances is a physiological one, but the circumstances which surround it in civilisation are so far from normal that it has become pathological. I ask the question in all seriousness. Is there a single incident in the management of normal labour which is not opposed to the physiological process of labour? Candidly I cannot discern one which is not opposed to it in some manner. Let me compare the course which I think Nature will prompt a woman to follow during labour with the cause which civilisation has imposed on her. I fancy that a cave-dweller's labour was somewhat as follows.

The Cave-dweller's Labour.

The woman washes herself at a nearby spring or stream, and she walks about and does some of her daily work during the first stage. There is no hip-bath in which she sits, there are no examinations or other interferences. The second stage comes on. She squats during the pains in an attitude of defæcation, thus enlarging her pelvic outlet, and gaining the help of gravitation on the descent of the child, and effectively using her abdominal muscles. The child is born, and the cord is either divided or left while the woman, still in a squatty position, expels the placenta. There is no question here of vaginal retention. If there is any delay, she hugs tightly a large stone, using it, together with her voluntary efforts, as a means of increasing intra-abdominal pressure. Then she probably lies down for a time, shortly to get up again to make the cave equivalent of a cup of tea. During the puerperium she is mostly on her feet. There is free drainage from the vagina, and, when she suckles her child, uterine action expels the lochia from the uterus. Her posture during labour and the puerperium causes a flow from the uterus to the vagina and thence externally. There is no opportunity for its reversal, and the aspiration of fluids from the vulva and the vagina cannot occur.

Civilised Labour.

The labour of her sister in civilisation is a very different matter. She enters a nursing home for her confinement, and begins her opportunities of infection by sitting in water in a bath which has just been used by another patient. Her vaginal orifice is somewhat patulous and water enters freely. She is then examined vaginally to see that all is normal, and later, perhaps a second or third time, to see if the doctor must be sent for. She has been sent to bed early in the first stage, and her position and mental anxiety make labour tedious. The nurse thinks it is getting too slow, so she presses on the fundus to try to hasten the expulsion of the child. The uterus is pressed down into the pelvis, and, when the pressure is relaxed, it rises again, and there is some vaginal aspiration which sucks into the vagina any fluid lying near the orifice. Such fluid has been infected by an unsterilised "wipe," and so more bacteria gain entrance.

The first stage continues, the patient is crying from nervousness and unrelieved pain, and so the medical attendant is summoned. He examines again and finds nothing wrong, so he is wise enough to give her a sedative and to wait. The patient, however, she comes into the second stage the forceps is applied. In a way she is a lucky woman, because it might have been applied during the first stage.

Where does the physiological process of labour come into this radical mismanagement? To begin with, civilisation forced the woman to have her baby in an abnormal attitude and in the confined circumstances of a nursing home, instead of in a normal attitude in an open space. Then her nurse sent her to bed when Nature wanted her to walk about. Then her doctor extracted her baby with forceps, when she would have delivered it herself if she had been allowed. Lastly, he extracted the placenta when Nature would have expelled it if the patient's attitude had not prevented her. Then civilisation again made her lie on her back or side in bed, while the normal discharges of the puerperium collected in the upper part of the vagina, and the septic organisms which had entered found both a medium in which to develop and an incubator to help development.

I submit that when a natural process has been diverted from the normal, to the extent that the labour of civilisation has been diverted from the labour of nature, it becomes to all intents and purposes a pathological process for which it is necessary to try continually to find new remedies, of which a perfect environment is one.

It is thus evident that current practice in regard to three out of the four cardinal factors I have mentioned differs markedly in the British Empire and in the group of low mortality countries. It is also clear that so far as the Queen Victoria's Jubilee Institute is concerned, the recognition of these factors is followed by an even greater drop in maternal mortality than occurs in Holland.

APPARENT EVERYDAY CAUSES OF MATERNAL MORTALITY.

I have certain definite ideas in regard both to the causes of maternal mortality and the ways by which it can be prevented. They are the result of my experience during the last five years or so as obstetrical consultant to the Health Department of New Zealand, and of the study of the writings of others on the subject both in Great Britain and in Australia. I express my indebtedness for both information and suggestion to Dame Janet Campbell and Dr. J. S. Fairbairn at home, to Dr. Marshall Allan and Dr. Sydney Morris in Australia, and to Dr. Sydney Allen in New Zealand. I believe that the practical causes of an unduly high maternal mortality, that is to say, the causes which are removable and whose removal will effect a marked reduction in such mortality, are as follows:

1. The conduction of normal labour by medical practitioners, because the latter of necessity bring to the case the dangerous elements of haste, of unnecessary interference, and of sepsis.

2. The insufficient medical education of both medical practitioners and midwives. In the case of the former the consequence is an insufficient skill to deal with the obstetrical diseases and difficulties which are their special province. In the case of the latter the consequences are an insufficient knowledge to enable them to appreciate the importance of and to practise a rigid aseptic technique, and, to a less degree, to make the general management of their patients inadequate.

3. The lack of due attention to antenatal care and antenatal diagnosis. The failure of the former results in unnecessary deaths from toxæmia, from pre-existing septic infection and from antepartum hæmorrhage. The failure of the latter results in unnecessary deaths from difficult labour and its sequelæ.

4. Unsuitable environment leading in maternity hospitals to deaths from septic infection acquired from other patients, and in private houses to deaths due to inability properly to treat obstetrical emergencies and to a less extent septic infection.

I trust no one will suggest that in expressing these opinions I am attacking the medical profession. If anyone should do so, my best answer is that, if so, I am attacking myself too. I am sure that, when I was Master of the Rotunda, the only one of the four causes which I have given above, and to which I attached sufficient importance, was the second—namely, adequate obstetrical education, and possibly also the fourth—suitable environment. The other aspects of the matter had not occurred to me, although they should have been obvious. I can only hope that soon they will represent the collective opinion of the medical profession.

The remedy suggests itself. Free the medical profession from what I have called the servitude of normal midwifery. Give the medical student sound and practical instruction in midwifery, and imbue him with the belief that one of his duties in life is to keep on adding to her knowledge. Teach the practitioner that his part in midwifery is antenatal care and diagnosis, the management of abnormal labour and of the abnormal puerperium, and postnatal care. Teach him, too, that amongst his patients he is an obstetrical parson, and that his text is the necessity for early medical advice and for suitable environment. Lastly, reform private maternity hospitals so that their environment may be that of a true hospital rather than of a lodging-house, or even of a private hotel.

I have quoted the statistics of the Queen Victoria's Jubilee Institute a number of times, and I will quote them once again. The total death-rate amongst its patients during a period of six years was two-fifths that of the obstetrical death-rate of the British Empire during the same period. If these figures are adjusted to make them more strictly comparable with official statistics, the death-rate per 1000 live births amongst the patients of the Institute was approximately one-third that of the Empire figures, while the unadjusted septic death-rate is less than one-third. Surely if an institution working amongst the poorer classes can attain this standard, the united efforts of the medical profession can do the same.

SUMMARY OF THE AUTHOR'S VIEWS.

I propose to vary the usual procedure, and to allow someone else to write the summary for me. In 1925 Dr. Sydney Morris, senior medical officer of health for New South Wales, wrote in a prize essay as follows:

1. "What public opinion has not yet realised is that the civilised woman requires attention not only at the actual confinement, but also some considerable time antecedent to the latter. Provided that the woman can obtain the services of a competent midwife for the actual confinement and the puerperium, together with the advice and supervision of a careful practitioner during the later months of pregnancy and in any emergency during the actual labour,

eclampsia amongst 13,067 patients. At the East End Maternity Home amongst 4173 patients there was not a single case of eclampsia. On the other hand, the attendances at the antenatal clinic numbered 11,881.

The only positive figures which I can place before you to show the effect of antenatal diagnosis on the prevention and prognosis of difficult labour are as follows. In England and Wales the death-rate from the "other accidents of labour" and from hæmorrhage was in the statistics from which I have already quoted 0·96 per 1000 live births, in Australia it was 1·22, in New Zealand it was 0·98. The corresponding death-rate amongst the patients of the Queen Victoria's Jubilee Institute was 0·33 per 1000 labours. That is to say, it was approximately a third of that of England and Wales and of New Zealand, and slightly more than a fourth that of Australia. I think that if you will recall the appalling consequences of undiagnosed and improperly treated contracted pelvis and particularly of the minor degrees of contraction, with its sequelæ failed forceps, failed craniotomy, delayed Cæsarean section, and septic infection, you will be able to estimate the effect of careful antenatal diagnosis yourself.

I have already suggested that the medical profession should give up the care of normal labour to midwives. I now suggest that they should replace this irksome and in every sense of the word unprofitable task by careful antenatal care and diagnosis, effective assistance in abnormal labour, and sufficient postnatal care. I quite recognise that many practitioners are trying and have tried for some years to give such care, in spite of the fact that the considerably increased demand it makes on their time goes unrewarded. Still the fact remains that, whereas in Holland every mother comes under the care of a medical practitioner during labour, in the British Empire it is only the minority who do so. Antenatal care and diagnosis is capable of removing almost completely the graver dangers of eclampsia and of obstructed labour by preventing the occurrence of the one and by the anticipation of the other. If it did nothing more than this it would probably reduce the maternal mortality-rate by something between 1 and 1·5 per 1000 births.

4. *Suitable Environment.*

I have explained what I intend to convey by this term—namely, everything which tends to promote the practice of asepsis, and which makes necessary intervention in obstetrical emergencies easily accomplished. I have no means of judging whether the environment of labour is better in Holland than in the British Empire, and so I will assume that it is the sole cardinal factor in which the practice of the two countries does not materially differ. Still its importance is such that I must discuss it. The value of suitable environment varies theoretically according to the circumstances and nature of the case. Thus, in a normal confinement normally managed in a private house, environment is possibly of small importance. Intervention is, and even vaginal examination may be, unnecessary. Consequently the risk of infection is small. In hospitals, public or private, environment is all-important on account of the increased risk of infection due to the presence of other patients. In abnormal cases, whether in private houses or in hospitals, environment is again all-important. So much in theory is probably right. In practice, however, seeing that unexpected complications may occur and necessitate intervention, suitable environment is always necessary.

The details of a suitable environment are all-important, but it is impossible to do more than touch on them. The aseptic environment must be such as to enable the labour to be carried out with the same degree of asepsis as is a surgical operation. It is strange that the truth of the fact is still unrecognised, and even contested, by so many people, and that it is possible to find a medical man removing tonsils in the morning with the strictest aseptic ritual and a placenta in the evening with none. Yet the removal of a placenta is possibly the operation most fraught with septic possibilities of any in the whole field of medicine. I am sure that the defence to this will be that the surroundings of an average case of labour make asepsis impossible. My reply is that we, as a profession, have had some 50 years at least in which to teach nurses and the public that these surroundings must be changed, and that we have not done so. Even at the present time, when a technique, which makes asepsis possible amidst bad surroundings, has been worked out in a satisfactory manner, medical practitioners are to be found who decry it as a useless and unnecessary expense and complication. Consequently environment does not improve, and the responsibility rests with us.

A very similar remark may be made regarding the environment which makes the treatment of obstetrical emergencies easy and safe. How many practitioners insist that the patient's room shall be so arranged that if, for example, postpartum hæmorrhage should occur, its treatment can be immediate and effective? I am almost afraid to ask the next question. How many practitioners carry with them the necessary appliances for its treatment, and prepare them beforehand so that they may be ready for an emergency? And yet the sole excuse for the presence of a medical practitioner during normal labour is that he is available for the treatment of the unforseen complication. Otherwise he is only an additional source of danger.

Again, the environment in private maternity hospitals is often no better than in a private home. And yet it is generally recognised that such hospitals are a danger rather than a benefit unless improved asepsis and general facilities more than compensate for the increased danger caused by the aggregation of patients.

CIRCUMSTANCES HAVE MADE LABOUR PATHOLOGICAL.

Someone may suggest, as has been so often suggested before, that it is absurd to worry about environment, and to treat as pathological what is a normal physiological function. This is a confusion of ideas, and one which in the past has helped to increase maternal mortality. It is true that the process of labour under normal circumstances is a physiological one, but the circumstances which surround it in civilisation are so far from normal that it has become pathological. I ask the question in all seriousness. Is there a single incident in the management of normal labour which is not opposed to the physiological process of labour? Candidly I cannot discern one which is not opposed to it in some manner. Let me compare the course which I think Nature will prompt a woman to follow during labour with the cause which civilisation has imposed on her. I fancy that a cave-dweller's labour was somewhat as follows.

The Cave-dweller's Labour.

The woman washes herself at a nearby spring or stream, and she walks about and does some of her daily work during the first stage. There is no hip-bath in which she sits, there are no examinations or other interferences. The second stage comes on. She squats during the pains in an attitude of defæcation, thus enlarging her pelvic outlet, and gaining the help of gravitation on the descent of the child, and effectively using her abdominal muscles. The child is born, and the cord is either divided or left while the woman, still in a squatty position, expels the placenta. There is no question here of vaginal retention. If there is any delay, she hugs tightly a large stone, using it, together with her voluntary efforts, as a means of increasing intra-abdominal pressure. Then she probably lies down for a time, shortly to get up again to make the cave equivalent of a cup of tea. During the puerperium she is mostly on her feet. There is free drainage from the vagina, and, when she suckles her child, uterine action expels the lochia from the uterus. Her posture during labour and the puerperium causes a flow from the uterus to

Vestibular examination on Feb. 24th gave the following results with cold water:—Right ear: nystagmus began at 51″ and lasted 54″. Left ear: nystagmus began at 49″ and lasted 120″.

The following report was made following radiographic examination of the skull on Feb. 24th: "Frontal and sphenoidal sinuses undeveloped. The sella turcica is small. There is a thick bony wall with well-marked anterior and posterior clinoid processes. There is no evidence of erosion. No abnormality of the skull is evident."

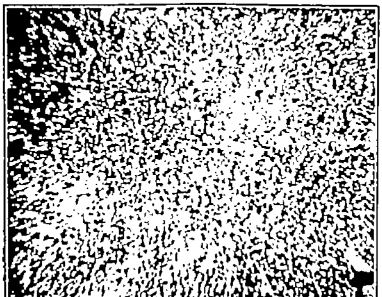
Summary and Commentary.

A previously healthy child of 8 years suffers from a progressive illness lasting between five and six months. Failure of hearing and spastic paraplegia are the first symptoms. Then there is rapidly increasing speech defect leading to complete dumbness. Sight is more gradually lost, and spastic paralysis increases in the lower limbs and extends to the upper. Finally, death occurs rather suddenly a few hours after the onset of acute symptoms of cerebral inflammatory type.

Post-mortem examination showed no abnormality except in the brain. The results of the pathological study of this organ are described by Prof. Woollard.

During life the recognition of the condition presented some difficulty. The diagnosis seemed to lie between a rapidly growing tumour of the brain and Schilder's disease. The chief arguments against the former were as follows: The signs and symptoms showed a very extensive and rapidly progressive lesion, but in spite of this there was none of the general signs of tumour. Headache, vomiting, and choked disc were absent, as were all other signs of increased intracranial pressure. The symmetry of distribution was in accord with recorded cases of Schilder's disease. The failure of hearing before that of sight had already been noted in a case recorded by Grainger Stewart, Greenfield, and Blandy[1] also, strangely enough, in a boy of 8 years. The subsequent blindness, unaccompanied by changes in the fundi, seemed to confirm the diagnosis.

FIG. 2.



Preparation stained by the Weigert-Pal method showing the demyelinisation of the fibres so that the white matter no longer takes the stain.

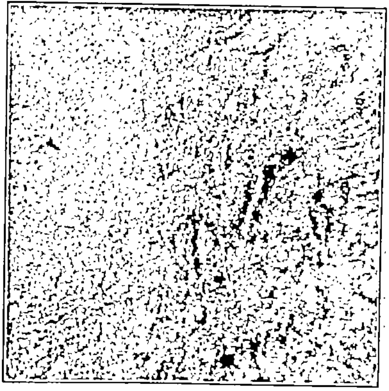
A good résumé of this disease appears in "Recent Advances in Neurology" by W. Russell Brain and E. B. Strauss[2] which includes a bibliography.

Pathological Notes by Prof. H. H. WOOLLARD.

It appears that 23 or more examples of this disease have now been collected. Of these the macroscopic examination of the brain has given a very similar picture in some 17. Microscopic analysis has been carried out in about six or seven, but this has naturally enough shown some divergence in detail though agreeing in essentials.

The present case of Dr. de Crespigny's was shown at a clinical meeting in Adelaide as a case of Schilder's disease, and it represents the first case discovered in Australia.

FIG. 3.



A high power view of the periphery of the demyelinised area. Weigert-Pal stain. Short irregular beaded fibres are seen.

Macroscopic Features.

The brain presented no external evidence of disease. There was no vascular injection of the pia mater, the convolutions were neither engorged nor flattened, and there was no hydrocephalus or sign of increased intracranial pressure. When the brain was sectioned there was disclosed an alteration in the white matter of both hemispheres (see Fig. 1), including the posterior part of the corpus callosum. The change gave to the white matter a fused gelatinous appearance easily distinguished from the normal, the transition between the two being abrupt.

The affected area of white matter was situated for the most part above the level of a horizontal section that would have passed through the genu and splenium of the corpus callosum. This is in agreement with other cases described. The fused gelatinous appearance of the white matter extended symmetrically in both hemispheres and the corpus callosum in its posterior fourth presented a similar appearance. This involvement of the corpus callosum has not been mentioned in the cases whose descriptions are available to us. The areas of white matter involved are those of the occipital and temporal regions. After fixation the changed areas of white matter became brownish and friable. The crumbling of the material made section cutting difficult.

It is a striking feature that the cortex immediately adjacent to the gelatinous white matter appears to be normal and is separated from the diseased area by a thin band of normal white substance. In the occipital lobe it is easy to discern the stria of Gennari with the unaided eye.

All descriptions of the affected white substance agree on the following points. The disease is limited to the occipital and temporal regions of the cerebrum, the area affected is large and continuous and extends symmetrically in both hemispheres. The grey matter immediately adjacent to the affected white matter appears normal, and the passage from affected white matter to normal areas is abrupt.

[1] Brain, 1927, l., 1.

[2] London 1929, p. 328 et seq.

of appetite, and insomnia. Mental retardation may be experienced, and often presents itself to the patient as a feeling that "the brain won't work," but in mild cases hallucinations and delusions are exceptional. There is often a history of previous attacks, followed by complete recovery, and sometimes a family history of more serious mental trouble. The relief of the insomnia is an important part of the treatment. Luminal is also effective in the treatment of insomnia associated with mental excitement, but larger doses, up to grs. 5, may then be required.

It is rash to say of any drug that it never gives rise to addiction, but it is very exceptional for luminal to do so. The risk of habit formation may be diminished in the neurotic patient with insomnia by letting him put the tablet by his bedside and take it only if he is not asleep half an hour after going to bed. After he has secured a few nights' sleep by means of the drug he will often fall asleep without its aid if he feels that it is readily available.

(3) *Aural vertigo* is a complex subject, upon which I can only touch lightly now. It is convenient to distinguish clinically two types of aural vertigo: (1) An acute type associated with an acute lesion of the internal ear, an acute labyrinthitis, sometimes secondary to middle-ear infection, acute or chronic, sometimes of undiscovered ætiology. (2) The second and commoner type is found in the patient who suffers from recurrent attacks of vertigo of varying severity associated usually with deafness and tinnitus. This is a heterogeneous group. Most cases have not had purulent otitis media, but the condition is usually secondary to blockage of the Eustachian canal, with deflected nasal septum, polyps, infected air sinuses, chronic catarrh, or dental infections.

In this second group luminal is an exceedingly valuable drug. I cannot remember a patient who was not greatly relieved by it, and in mild cases complete freedom from vertigo is often produced in a few days. I give ½-gr. doses three times a day at first, and later reduce the dose. Luminal, of course, does not remove the cause of the vertigo, which must be sought and treated by otological methods.

Luminal is an excellent vestibular sedative in conditions of acute labyrinthitis, and I have used it also for vertigo due to lesions of the vestibular tracts and centres—for example, in encephalitis lethargica and disseminated sclerosis. It is useful as a preventive of sea-sickness.

(4) *Pruritus.*—I owe my acquaintance with the antipruritic effects of luminal to Dr. W. J. O'Donovan. It is especially valuable in cutaneous affections in which a large neurotic factor plays a part, such as pruritus ani. Used in gr. ½ doses and combined with appropriate local treatment it greatly diminishes the pruritus and so helps to break the vicious circle in which scratching keeps up an abnormal and irritating state of the skin.

(5) *Miscellaneous Disorders.*—Luminal is also useful as a sedative in chorea, whooping-cough, and exophthalmic goitre, and other uses for it will, no doubt, suggest themselves.

ABOLITION OF LETTERS OF RECOMMENDATION.—The governors of the Norfolk and Norwich Hospital have abolished the use of letters of recommendation on the ground that 75 per cent. of the patients are members of the contributory scheme, and that others can be admitted almost automatically on the advice of their medical men.

A BANKERS' HOSPITAL TRUSTEE.—The original trustees of the Yorkshire Home for Chronic and Incurable Diseases at Harrogate, which was established in 1881, have long been dead, the trust deed has been lost, and no new trustees have been appointed. The resulting difficulty has now been removed by the appointment of the National Provincial Bank as trustee for an honorarium of 10*s.* per cent. The rules have, at the same time, been amended by substituting the word "resident" for "patient." The word "hospital" has been deleted at the request of the inmates, on the ground that, as the National Health Insurance does not pay benefits to patients in hospitals, they are in danger of being denied their rights.

TWO CASES OF
HUMAN INFECTION BY THE AMERICAN HOG-CHOLERA BACILLUS.

By DAVID NABARRO, M.D., F.R.C.P. LOND.,
DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON;

P. BRUCE WHITE, B.SC. WALES,
ASSISTANT BACTERIOLOGIST, NATIONAL INSTITUTE FOR MEDICAL RESEARCH;

S. C. DYKE, D.M. OXF., M.R.C.P. LOND.,
CONSULTING PATHOLOGIST TO WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL;

AND

W. M. SCOTT, M.D., B.SC. EDIN.,
A MEDICAL OFFICER OF THE MINISTRY OF HEALTH.

WITHIN the salmonella series of types the porcine strains referred to as *Bacillus suipestifer* (*B. choleræ suis*, or hog-cholera bacilli) and the human strains to which—in flagrant disregard of its original usage—the term *B. paratyphosus* C has of recent years been variously applied, form a cluster of species with specially close serological affinities. The composition of this cluster has been the subject of numerous studies, and one of us (White, 1926), piecing together and extending the work of others, concluded that these strains were divisible into four sharply-defined types: (1) Eastern or Hirschfeld, (2) American *suipestifer*, (3) European *suipestifer*, and (4) Glässer-Voldagsen or Ferkeltyphus.

The main differential characters of these types are set out in Table I.

TABLE I.—*Differential Characters of Four Types.*

—	Fermentation of—				Production of H_2S.	Serological relations.	
	Mannite.	Dulcite.	Arabinose.	Rhamnose.		Specific phase.	Non-specific phase.
Eastern or Hirschfeld type	AG	AG	AG	—*	+ +	Closely similar.	(See below).
American *suipestifer* type..	AG	—	—	AG *or* —	—		
Ferkel typhus type—							
Glässer strains	—	—*	A(g)	A(g)	+		
Voldagsen ,,	—	—*	A(g)	A(g)	+	None.	
European *suipestifer* type..	AG	—*	—	AG	+ +		

Non-specific phases of American and Glässer strains are to all intents identical; European and Voldagsen strains differ therefrom only by lack of any trace of specific phase antigen. The non-specific phase of the Hirschfeld type differs definitely from all the above by its deficiency in certain antigenic components.

A = acid; G = gas; (g) indicates that small amounts of gas are produced by some strains; — = No fermentation or no H_2S produced; —* indicates regular or occasional late fermentation; + = H_2S formed.

While the Hirschfeld type is known only from typho-septic disease in man, and while the European *suipestifer* type has been repeatedly encountered as a cause of food-poisoning outbreaks and of isolated cases of paratyphoid, there appear to be only two records of isolation of the American *suipestifer* bacillus from human sources; these are due to Krumwiede, Provost, and Cooper (1922), who describe a small outbreak of food poisoning due to this form, and to Hicks (1927), who isolated the organism in Shanghai from the blood of a paratyphoid sufferer. Furthermore, up to the present time the American *suipestifer* bacillus has not been shown to occur in Europe; it did not appear among 37 porcine strains collected by one of us (P. B. W.) from England and the continent; its known strongholds are America and Japan.

It is therefore of interest to record two cases in which the organism was isolated in this country and as an apparent cause of disease in man.

NABARRO AND WHITE'S CASE.

V. R., a girl aged 8 months, was brought to the Hospital for Sick Children, Great Ormond-street, on Dec. 2nd, 1926, with the history of having been ailing for the past two months and of having lost the use of the arms from the shoulder to the elbow, especially the right.

On examination the child was well developed, but rather pale. Both upper arms were held rigidly at the side of the chest, and there was generalised swelling of the shoulder region on both sides. The shoulders were tender to palpation, although gentle, passive movements did not seem to cause pain. Radiographic examination showed periosteal thickening at the outer side of the upper arm, and of both humeri, also a small area of rarefaction at the upper end of the left diaphysis, and doubtful erosion at the upper end of the right diaphysis. No other joints were swollen, and the child had no fever. The right shoulder-joint was aspirated and about 1 c.cm. of thin, turbid fluid removed. This was investigated and an organism of the salmonella group was isolated.

Agglutination Tests with the Patient's Serum.

Samples of blood were taken on the eighth and thirteenth days after admission to hospital and were tested for salmonella agglutinins. Oxford standard suspensions of *B. paratyphosus* B and *B. paratyphosus* C (presumably Hirschfeld's bacillus), and a suspension of the organism from the joint fluid were clumped on both occasions up to serum dilutions between 1000 and 2500; Oxford suspensions of paratyphoid A, Gaertner and "Mutton" (Aertrycke) type bacilli were not agglutinated at dilutions 25 and above. An absorption test showed that saturation of the serum with paratyphoid B bacilli did not appreciably reduce its titre for Hirschfeld's bacillus or for the patient's own organism; another suggested that Hirschfeld's bacillus was unable to exhaust the serum of agglutinins for the patient's strain.

Two years later (Dec. 17th, 1928), when the child was called up for examination, its serum still clumped paratyphoid C-*suipestifer* bacilli up to dilutions between 125 and 250.

Widal tests, made in March, 1927, with samples of blood from the parents of V. R. revealed no agglutinins for any salmonella tested.

Cultural and Serological Features of the Organism Isolated.

In morphology, in motility, in failure to produce indol, to liquefy gelatin, to clot milk, to attack lactose, saccharose, and salicin, and in its gaseous fermentation of glucose and mannite the organism presented the usual characters of the salmonella group. Arabinose and inosite were unfermented; acidity did not appear in dulcite peptone water till the third week of incubation; lead acetate added to broth cultures remained undarkened during 14 days. These peculiarities are together characteristic of the American *suipestifer* or hog-cholera type.

The organism was found to be a typical diphasic form, and agglutination tests performed with its specific and non-specific phases and the phase antisera of various salmonella types grouped the strain unequivocally with the bacilli of the paratyphoid C-*suipestifer* series of types.

A number of comparative absorption tests were carried out. The essential results may be summarised as follows:—

1. The specific phase of strain V. R. completely exhausted the specific phase antisera of two America *suipestifer* strains (titre reduced from 10,000 and 20,000 resp. to <100); it almost exhausted a specific phase Hirschfeld type serum (20,000 to 200).

2. The non-specific phase of strain V. R. completely exhausted the non-specific phase antisera of the same two American *suipestifer* strains (25,000 and 50,000 resp. to <100) and equally exhausted the high titre sera of two European *suipestifer* strains. Similarly applied to these sera the non-specific phase of Hirschfeld's bacillus left considerable agglutinins (1000–5000). Acting on a non-specific phase Hirschfeld type serum the non-specific phase of V. R. was almost as effective in removing agglutinins as the homologous Hirschfeld strain.

3. A mixed phase serum prepared against strain V. R. showed an homologous specific phase titre of 25,000. This was reduced to <100 by treatment of the serum with specific phase American *suipestifer* bacilli, to 250 by treatment with specific phase Hirschfeld bacilli, and was unaffected by saturation with European *suipestifer* bacilli. The non-specific phase titre of the same serum was 100,000. Heavy doses of non-specific phase American *suipestifer* and of European *suipestifer* bacilli reduced this titre to <200, but the corresponding phase of Hirschfeld's bacillus left well-marked non-specific phase agglutinins (titre 10,000).

In fine the strain V. R. was found to correspond exactly and exclusively with typical *suipestifer* strains from the United States. Incidentally it may be noted that another strain, "Cole," also isolated by one of us (D. N.) from a case of joint abscess in a child, was identified as a typical European *suipestifer* strain, adding yet another instance of human infection by this organism. It would seem that the European *suipestifer* bacillus is particularly apt to attack young children and occurs as frequently in localised disease as in generalised febrile infections and gastro-enteritic poisoning.

DYKE AND SCOTT'S CASE.

The patient, aged 20, a labourer, was admitted to the Wolverhampton and Staffordshire Hospital on June 20th, 1927, having been ill for four days.

The onset of his illness was said to have been sudden with generalised indefinite pain and deafness. There was no diarrhœa and no vomiting. Delirium appeared in 48 hours, at first intermittent, but on admission persistent. It was of a violent character, the patient crying aloud, struggling, and continually attempting to get out of bed. The temperature on admission was 103° F., pulse 110, and respirations 28. The abdomen was distended but soft; the spleen could not be felt. Except some crepitations at the apex of the right lung there were no abnormal physical signs.

The patient died in hospital five days after admission, the duration of the illness thus being nine days. Delirium persisted during the whole of his stay in hospital until the final coma; the temperature ranged between 103.5° and 101° F. except for a brief period on the fourth day when it fell to normal; the pulse ranged from 116 to 140 most of the time and rose to 160 shortly before death. The bowels were opened normally about once daily; stools were firm and well formed. The urine showed no albumin and no deposit on centrifugalisation. On the fourth day after admission a large purpuric area about the size of the palm of the hand appeared on the left flank.

Autopsy.

The morbid changes found were those characterising an acute infection. The heart muscle was soft and friable; there were no abnormalities of the valves. The serous cavities showed no free fluid, but small purpuric flecks were present on both parietal and visceral pleura and on the surface of the heart. The intestines appeared normal; the liver was pale and fatty; the kidney showed a most intense cloudy swelling, the capsule stripping readily; the spleen was moderately enlarged, dark red, and soft; the lungs showed congestion, but no consolidation; the tracheal mucous membrane was moderately inflamed; there were no macroscopic abnormalities in the brain.

Bacteriology.

A blood specimen was taken for culture on the third day after admission. This showed in 48 hours an abundant growth of a small Gram-negative motile bacillus which grew readily on all the ordinary laboratory media. Cultures from the heart blood and spleen post mortem yielded a similar micro-organism. Mice inoculated with cultures of this bacillus died in one to four days with septicæmia.

In view of the obscure nature of the illness the case was reported to the Ministry of Health, and the circumstances were then investigated locally by Dr. E. Wilkinson, one of the medical officers of the Ministry. Inquiry showed that there had been no cases of similar illness in the family of the patient nor in the neighbourhood, and no possible source of infection has since been discovered.

Identification of B. suipestifer, Group I.—A culture of the bacillus isolated post mortem was received at the laboratory of the Ministry of Health on June 30th, 1927. In colony and culture it resembled a salmonella; it fermented glucose and mannite with production of acid and gas and left unattacked lactose, saccharose, and dulcite; it failed to produce blackening of lead acetate even after ten days' growth. Colonies were tested for agglutination with the sera prepared with various salmonella types. It was found that 80 per cent. of the colonies agglutinated with the "specific phase" sera of *B. paratyphosus* Hirschfeld and *B. suipestifer* Indiana 49, but not with the sera of other types. With various "group phase" sera 20 per cent. of the colonies agglutinated, such colonies giving no agglutination with "specific phase" salmonella sera. It was thus possible by direct serological examination of the colonies to report within 24 hours that the infection was due to a diphasic salmonella belonging to the *suipestifer*-paratyphosus C series. Since such a salmonella had not at that time been described as indigenous in England further serological work was undertaken to determine to which of the sub-types of the *suipestifer*-paratyphosus C series it belonged and especially to see if it was of the American sub-type not hitherto found in human infections. The matter was mentioned to Bruce White, who proposed that our Wolverhampton case should be published jointly with the similar case in London already investigated by Nabarro and himself.

Specific and group phase cultures of the Wolverhampton strain were used to produce agglutinating sera in rabbits (intravenous doses of 0·1 c.cm., 0·25 c.cm., 0·5 c.cm., and 1 c.cm. of chloroformed broth culture) and absorption experiments set up as shown in Table II.

TABLE II.—*Absorption Experiments:* (A) *Group Phase Antigen.* (B) *Specific Phase Antigen.*

Serum.	Absorbed by—	(A) Titre (group phase).	(B) Titre (specific (phase).
Para-C Hirschfeld	Wolverhampton	<100	200
	B. suipestifer Indiana 49	<100	200
	Unabsorbed	25,000	6,000
Wolverhampton	Para-C Hirschfeld ..	3,000	800
	B. suipestifer Indiana 49	<100	<100
	Unabsorbed	25,000	6,000

These absorption experiments were performed by emulsifying about 100 mg. of the moist growth from agar plates in 2 c.cm. of a 1 in 50 dilution of agglutinating serum. This quantity sufficed in each case to remove all the agglutinin when the homologous strain was used.

The experiments show that the group-phase of the Wolverhampton strain and of the American *B. suipestifer* Indiana 49 removes all the group-agglutinin from the Hirschfeld serum. The group-phase of the *B. paratyphosus* C strain (Hirschfeld) leaves a considerable proportion of the agglutinin in the Wolverhampton group-phase serum, whereas from the latter serum the American *suipestifer* removes the agglutinin entirely. The specific phase of both Wolverhampton and Indiana 49 removes a large proportion of the specific agglutinin in the paratyphosus C serum, but leaves a small fraction unaffected, and the specific phase of *B. paratyphosus* C, while absorbing a considerable amount of the specific agglutinin from the Wolverhampton serum, leaves a fair proportion uncombined, although the American *suipestifer* removes it completely. Other absorption experiments show: (1) that the specific agglutinin for the American *suipestifer* Indiana 49 can be completely removed by the specific phase of the Wolverhampton strain; and (2) that a group II, "European;" *suipestifer* leaves uncombined only the small proportion of specific agglutinin in a group phase Wolverhampton serum. This was shown by Bruce White (1926) to be characteristic of the relationship between group I. and group II. *suipestifers*. (The European *suipestifer* employed was that obtained in the outbreak of gastro-enteritis at Offenbach in 1926 and described by Braun and Mündel (1927).

It is interesting to note that the conclusion arrived at by serological analysis—namely, that the Wolverhampton bacillus is a group I. or American *suipestifer*, is in agreement with the cultural indications, the absence of dulcite fermentation, and the failure to blacken lead acetate being characteristic of the American strains of *suipestifer* as contrasted with *B. paratyphosus* C of oriental origin.

THE TREATMENT OF PURULENT PLEURISY BY PLEUROTOMY AND BALNEOTHERAPY.*

BY DR. J. S. PASSERON,
SURGEON TO THE SAN ROQUE'S CHILDREN'S HOSPITALS, BUENOS AIRES.

THE evacuation of pus from the pleural cavity is best attained by making a complete opening under local anæsthesia in an intercostal space along the posterior axillary line of the side affected. The superficial incision can be made anywhere, but the patient is transferred to a bath for the purpose of deepening the incision under water, the temperature of the bath being 104°–108·6° F.

Technique of Treatment.

The bath is flamed and filled to a convenient level, and the patient is washed down with soap and water. He sits in the bath so that the water covers the superficial incision, which is then deepened until pus is found. The edges of the wound are held apart by large forceps like sinus forceps. This brings about an interchange of pus and water, and greatly favours the expulsion of fibrinous exudations by respiratory impulse. The greatest possible quietness is maintained, and when the pleural lavage is considered sufficient the patient is lain down outside the bath; this brings about the expulsion of almost all the remaining fluid under respiratory impulse. A pad of sterilised cotton-wool is then placed over the wound and makes it a closed cavity. Under these conditions the surgical diaeresis performs the function of a valve which, by excess pressure, allows the intrapleural air to escape without admitting an equal amount; this promotes expansion of the lung.

Later treatment consists in repeating the bath after washing down, opening the wound fully by large forceps, and thereby promoting lavage of the pleural cavity. The duration, frequency, and temperature of the baths should be governed by the general condition. In serious toxic cases I advise two baths per diem, of five minutes' duration; in cases of medium intensity a daily bath of ten minutes suffices. According to his condition and stamina, the patient should get up and gain strength. The diet should be as nourishing as possible.

While the patient is in the bath it is interesting and very easy to discover if the empyema communicates with a bronchus. An adult is told to place his hands over his mouth and blow through them as if warming his hands on a cold day, then to close his lips tightly, press firmly against them with his hands, and keep up the pressure of air in his respiratory passages. Should there be communication with a bronchus this air will escape from the wound and bubble into the water as often as the test is repeated—that is to say, to an indefinite extent. This repetition differentiates the air from gas which may have been formed by organisms or air which may have entered accidentally. The bubbling is exactly the same as if air were injected under water through a small tube. Infants cry, and so produce the same result. This manifestation, first observed by Dr. Enrique Foster while applying the treatment experimentally in his clinic for unweaned infants, is very important in prognosis. It indicates: (1) that the empyema springs from broncho-pneumonia, and (2) that it opposes the principle of treatment which endeavours to obtain a closed cavity. When the empyema communicates with a bronchial tube, the beneficial principle of a pneumothorax closed by a valve, such as is obtained in other forms of pleurisy, is not possible or is much impeded, inasmuch as the communicating bronchial tube, in all those efforts of the patient which are so useful for expanding the lung, injects air into the pleural cavity, counteracting the favourable results of the effort. Pleurisy with bronchial involvement is more intractable to treat and of longer duration than closed pleurisy.

---

* Translated from a paper read before the Surgical Congress at Buenos Aires, 1928.

Underlying Principles.

The hot bath has a very important effect on the general condition, for it brings about elimination of toxins by profuse perspiration and diuresis, and also by the neuro-nutritive stimulus of the bath; it improves appetite and makes the patients more active, thereby increasing their recuperative powers.

The advantage of this method is shown by the reduced period of treatment, which varies between 15 days in the most successful cases and two months. The work performed by Drs. Enrique Foster and Fernando Arancibia in the Children's Hospital shows that better results have been obtained with the bath than with other methods of treatment of empyema in unweaned infants. The peculiar gravity of empyema in unweaned children was taken as a test of the treatment.

The chief difficulty which the treatment has to overcome is the prejudice of the surgeons who, in accordance with the inflexibility of the teaching of asepsis, are antagonised by the lack of respect which this method shows for suppurating cavities, even when the rules of surgical cleanliness are meticulously observed. Nevertheless I venture to state that, no matter how much surprise the method may cause on account of its mode of operation, fundamentally it has not infringed any principle. What is obtained by asepsis in these cases is only relatively valuable compared with the process on which it acts. Taking as example a case of simple pneumococcic empyema, the standard procedure cannot avoid microbic contamination, to which the cavities are inevitably exposed by prolonged drainage. Asepsis can only prevent the penetration of germs of great virulence, which are kept remote from the wound more easily than the common germs living in immediate contact with it. It may be objected that the bath cure allows the common cutaneous germs to reach the suppurating cavity, but in fact it illustrates the benefit of hot water upon the general and local condition, and, at the expense of a certain concession in surgical conventions, gives the great advantages of operating with efficacy, simplicity, and ease.

Statistical Data.

My cases include the following:—

(1) Ten patients treated by me in the clinic of Dr. Marini: of *eight adults, one died of pneumococcic meningitis, after* being clinically cured of a fœtid pleurisy on the left side with bronchial involvement, which developed in two months; the other seven were cured. Of two children, one aged 4 years and the other aged 18 months, both were cured.

(2) Four cases treated by Dr. Nicasio Cuneo: two adults were cured, and two children, one aged 3 years and the other aged 6 years, with double pleurisy (the second occurring eight days after the operation for the first), were both cured.

(3) Thirty-nine cases treated in the Children's Hospital: of 15 over two years of age, 12 were cured and 3 died; of 24 under two years of age, 9 were cured and 15 died.

(4) One case treated by Dr. Foster in private practice, a child of 22 months, was cured.

Summarised, these figures are:—

Adults.—10: 9 cured, 1 died.

Children over two years.—16: 13 cured, 3 died.

Children under two years.—26: 11 cured, 15 died.

Statistics given by Drs. Foster and Arancibia on 72 cases of pleurisy in unweaned infants in the Children's Hospital, treated by different methods, show a percentage mortality as follows:—

	Mortality.
By minimum pleurotomy and drainage	90
By costal resection and drainage..	85
By puncture	65
By pleurotomy and bath cure	36

Conclusions.

(1) Unless a more extensive statistical study shows different results, it appears that purulent pleurisy is cured in greater proportion, in a shorter period, and with less difficulty by the bath than by any other method.

(2) When appreciating results we must remember that the great majority of cases of purulent pleurisy are complications of developing pulmonary affections.

PRINCIPLES IN THE TREATMENT OF COMMON DEFORMITIES.*

BY NAUGHTON DUNN, M.B. ABERD.,
SURGEON TO THE ROYAL CRIPPLES HOSPITAL, BIRMINGHAM
AND LECTURER ON ORTHOPÆDIC SURGERY IN THE
UNIVERSITY OF BIRMINGHAM.

ORTHOPÆDIC surgery is so closely associated with function that the patient is in an exceptionally good position to judge of the practical success or failure of what is done for him. Often perfect restoration of function is impossible, and it is therefore important that, before treatment is begun, the patient and parents should understand clearly how much improvement is to be expected; otherwise what we may consider a brilliant surgical success will to them be a disappointment.

Deformities are associated with changes in bones, joints or muscles, and their causes must be understood before the possibilities of cure can be assessed.

Causes of Deformity.

In *rickets* there is a deficiency of lime in the bone, and the softened bone readily adapts itself to posture; deformity is thus influenced by the incidence of body-weight. In *arthritis* the instinctive effort to prevent pain causes spasm of all muscles controlling the joint, and the stronger muscle groups determine the position in which the joint is fixed. The position of deformity in arthritis of any joint is therefore almost constant; it is adduction of the shoulder, flexion of the elbow and wrist, flexion and adduction of the hip, flexion of the knee and equinus deformity of the foot. So in *infantile paralysis* the deformity is determined by two factors: (1) persistent posture, and (2) the deflection of the joint towards the stronger group of muscles. These deformities once established will, as a rule, be aggravated by the incidence of body-weight. Early treatment by splintage would prevent their onset, but *as a rule* we see the patient when deformity is established, and the problem is the one of restoring function. The methods commonly adopted for this are: (1) gradual correction of the deformity; (2) forcible correction of the deformity; (3) surgical exposure with division of tight structures; and (4) operations on bone. In cases in which the loss of function is not associated with deformity, the possibilities of improvement by operations on joints or tendons must still be considered.

---

* Being a lecture delivered before the Chartered Society of Massage and Medical Gymnastics on Oct. 16th, 1929.

Restoration of Function.

Gradual correction of deformity is a method which was successfully employed before many of the operations at present practised were surgically safe, and we can assess the value of modern operative methods only if we have experienced the possibilities of correction of deformity by gradual splintage. It has been my good fortune to be trained in a school in which success in the application of the principles of gradual correction of deformity has been very striking. I have learned that nature resents tension and allows relaxation of structures to which it is constantly applied.

It is generally agreed that division or elongation of muscles reduce their power, so that methods of gradual correction of deformity have a definite advantage in dealing with ischæmic palsies and infantile paralysis where muscle power is already deficient. Again in deformities resulting from rickets there is seldom any indication for operation while the disease is active. In practically all children under the age of 4 the deformities can be corrected by splintage, while the necessary general treatment to harden the bones is being applied. Gradual correction is the method which can be applied in cases of arthritis of joints before the stage of true ankylosis. It is also the method of choice for the early treatment of congenital club-foot.

Forcible correction of deformity is mainly utilised for the correction of claw-foot in children and young adolescents. Considerable force is also necessary for the reduction of congenital dislocation of the hip-joints, and also in cases of club-foot in which treatment has been delayed.

Surgical division or elongation of tight structures, as a preliminary to correction of deformity, is usually necessary in cases of torticollis, and to weaken muscle groups which are causing deformity in cases of spastic paraplegia.

Operations on bones or joints may be required to correct alignment in cases of established deformity, or to improve function by arthrodesis—i.e., by promoting sound bony union of certain joints. These operations are perhaps the simplest and most satisfying both to the patient and surgeon. Those commonly practised are: osteotomy of the upper or lower end of the femur in cases of established rickety deformity; operation for malunion of fractures, or deformity resulting from arthritis; and arthrodesis. This last operation is of special value in certain cases of loss of function resulting from paralysis, for instance, in cases of loss of power in the deltoid with active scapular muscles a very useful range of controlled movement of the limb is possible if the humerus is arthrodesed to the scapula in a position of moderate abduction. The controlled movement of the scapula is then transmitted to the limb, and in young patients with good scapular muscles the range of movement is so good that it is often difficult to detect the original disability.

In cases of paralytic deformity of the foot removal of bone and arthodesis of joints has proved very valuable. On examining a paralytic deformity of the foot, clinically or by X rays, it will be noticed that deformity has taken place mainly at the mid-tarsal and subastragaloid joints, and that there is little alteration of the relation of the astragalus to the bones of the leg. The to-and-fro movement at the ankle-joint is the important one for locomotion.

In infantile paralysis we cannot restore power to the atrophied muscles, but by reducing the number of joints which depend on them for stability we not only prevent recurrence of deformity, but leave such muscle power as is present for control of flexion and extension of the ankle-joint. This operation is known as stabilisation of the foot, and it consists essentially of correction of deformity by removal of bone at the mid-tarsal and subastragaloid joints, with after-treatment which ensures that the os calcis, astragalus, and fore part of the foot become united as one bone in a good weight-bearing position. Subsequent deformity at the mid-tarsal and subastragaloid joints is not then possible. This operation may be utilised in other types of fixed deformity of the foot, such as old-standing club-foot, or to relieve pain in cases of tarsal arthritis.

Tendon Transplantation and Tenodesis.

The late war gave many of us an extensive experience of tendon transplantation in the restoration of function. The causes of failure in many operations previously practised were understood, and certain procedures are now recognised as essential for success. These are: (1) That before operation correction of deformity should be complete. (2) That the transplanted muscle should run in a direct line from its origin to its new insertion. (3) That the muscle should be of sufficient power to meet the strain which would be imposed on it. (4) That in the lower extremity a tendon should only be used to replace one of its own group—i.e., one normally in action with it. (5) That the tendon should be sutured under considerable tension.

The re-education of an individual tendon to act apart from its group appears to be more practicable in the upper extremity, where the action of individual muscles is more specialised than in the leg. The movements employed in locomotion are simple and controlled by groups of muscles, so that it is difficult to re-educate a muscle to act apart from its own group. In cases of paralysis of the quadriceps muscle transplantation of the sartorius or tensor fascia femoris to the patella is found effective. In the foot there are for practical purposes only two groups of muscles—viz., the anterior tibial, in action in dorsiflexion of the foot, and the peroneal and posterior tibial associated in action with the tendo Achillis in plantar flexion. Any of the anterior muscles may successfully replace one another—e.g., the tibialis anticus may be successfully transplanted to the outer side of the dorsum of the foot in paralytic varus, or the extensor longus hallucis may be transposed to the tibialis anticus. On the other hand, no tendon transplanted from the peroneal or posterior tibial group will be effective in replacing the loss of active dorsiflexion. The posterior tibial and peroneal muscles form one group. All are in action in extension of the ankle, so that they may be used to replace one another with certainty of success. The successful use of these muscles to replace a paralysed tendo Achillis is a striking illustration of the group action of muscles in the control of the foot.

In the upper extremity certain tendon transplantations have proved most valuable in the restoration of function; thus in musculo-spiral paralysis we find that loss of extension of the wrist, fingers, and thumb can be surely replaced by transference of the pronator radii teres, flexor carpi radialis, and flexor carpi ulnaris to the extensors of the wrist, fingers, and thumb.

Tenodesis is a method of utilising paralysed tendons as ligaments so as to limit movement of joints. It consists of embedding the proximal portion of the tendon in bone, and its use may be illustrated by the anchoring of a portion of the tendo Achillis to the lower third of the tibia to prevent calcaneus deformity in cases of paralysis of this muscle.

Although I have dealt mainly with the correction of established deformity, it must be recognised that many of these can be prevented by early treatment. For this a knowledge of simple splintage is essential. Whether we are dealing with fractures, arthritis, rickets, or paralysis the type of deformity is almost constant and its cause must be understood. Its prevention or correction will then present little difficulty.

Clinical and Laboratory Notes.

IMPLANTATION OF EPITHELIOMA IN THE ALVEOLI OF THE MAXILLA FROM PRIMARY GROWTH IN TONGUE.

BY J. BAGOT OLDHAM, F.R.C.S. ENG.,
ASSISTANT SURGEON, NORTHERN HOSPITAL, LIVERPOOL;
SURGEON, BIRKENHEAD GENERAL HOSPITAL.

THE *following case seems to suggest that the* extraction of diseased teeth as a preliminary to operation for epithelioma of the tongue may have unfortunate results.

A man, aged 50, came to the Northern Hospital complaining of an ulcer and soreness of the tongue. He gave a history of excessive smoking and of syphilis 23 years ago. He stated that six months before he had noticed a white patch, presumably leucoplakia, on his tongue. About three months ago the tongue became sore on the right side, and a month later an ulcer formed. Lately he had noticed that he was salivating excessively, especially at night, and that he had pain now and then at the angle of the jaw. During the last month he had difficulty in speech, and deglutition had caused pain at the angle of the right jaw.

Examination.—The man was well built and apparently healthy. The right side of the dorsum of the tongue was almost completely occupied by an ulcer, which extended from the right edge to near the middle line; it came forward almost to the tip of the tongue, and extended back and just on to the anterior pillar of the fauces. The edge was irregular and heaped up, and the base sloughy and friable. The left half of the tongue showed many patches of leucoplakia. Movement of the tongue was restricted, and on attempting to protrude the tongue it deviated to the right. Salivation was very marked, and was streaked with blood. The teeth were all deficient, except for the two upper right molars, which were jagged. Pyorrhœa was marked. The submaxillary glands were enlarged and hard on the right side; they were not attached to the jaw. Speech was a little indistinct.

Operation.—Pending operation, the man was transferred to the dental surgeon, who removed the two molar teeth. He was admitted on June 10th, 1927, about one week after the teeth had been removed. Owing to the sloughy condition of the tongue, it was decided to excise the tongue before removing the cervical glands. On June 17th I tied the right external carotid artery, and then with the diathermy excised the right half of the tongue, both pillars of the fauces, and the tonsil. Under anæsthesia it was found that the tongue was indurated very far back, well on to its base, so that the excision was a formidable task. The late Prof. E. E. Glynn reported: Typical squamous-celled carcinoma with many cell nests.

Sequel.—Convalescence was uneventful, in spite of the size of the raw area. The temperature never rose above 99° F., nor the pulse-rate above 90. During the first two weeks the submaxillary glands showed some inflammatory enlargement. On July 2nd he was allowed to go home on the understanding that he would return for removal of the cervical glands. For some reason he did not return till August 31st, when it was found that the glands had become slightly larger and harder. On examining the mouth it was found that the right side of the mouth had healed up completely, and there was no evidence of any local recurrence. On the left tonsil there was a small ulcer, half an inch in diameter, irregular, friable, and obviously malignant. It spread on to the soft palate, but did not involve the tongue or the anterior pillar of the fauces. The two sockets of the right upper molars which had been removed were filled with fungating masses which projected almost half an inch from the alveolar margin. Although touching, the two masses were quite distinct.

As the removal of the right half of the tongue had been so successful, it was decided to try to remove the recurrences. On Sept. 2nd I excised with the diathermy the masses in the tooth sockets, and diathermised the surrounding tissues. I then excised the left tonsil and fauces, the left half of the soft palate, and that part of the tongue in proximity to the tonsil. The pathologist's report on tonsillar and alveolar fragments was: squamous-celled carcinoma exactly similar to lingual growth.

As before, the man showed little after-effects from the operation, but the area took a long time to clean up. In the meantime the glands showed so much inflammatory reaction that it was considered inadvisable to attempt an immediate excision. About a month after operation the mouth was clean, but the glands were now so enlarged, and the toxic absorption had so devitalised the man that he was allowed to go home on Oct. 15th. His private doctor kindly kept me informed of his progress. The mouth improved steadily, and there was never any sign of recurrence, either in the scar or remotely, but the glandular condition went rapidly from bad to worse, and the man died in December.

SOME OBSERVATIONS ON GAS AND OXYGEN IN GENERAL SURGERY.

BY A. WINGATE HENDERSON, M.B. ABERD.,
SENIOR HOUSE SURGEON, ROTHERHAM HOSPITAL.

IN November, 1928, gas and oxygen, administered through a McKesson machine, was instituted in this hospital. Since that date I have observed its effects on a series of 165 cases, from careful examination of which certain deductions can be drawn. I have been struck by the following points in all patients who have had gas and oxygen: (*a*) the comparative rarity of post-anæsthetic sickness; (*b*) the early demand for food; (*c*) the complete absence of post-operative chest complications except in two cases.

No matter what the type of case—a big abdominal or a simple appendix—the ruling-out of any tendency to post-anæsthetic sickness and chest trouble is a most important argument in favour of gas and oxygen in general surgery. I have had frequent opportunities of observing the condition of patients who have had gas and oxygen and those who have had chloroform and ether mixture or ether, and in all cases I found a most striking contrast in the immediate post-operative period. The climax of the contrast was in every case on the day following operation, and despite precisely similar surgical treatment the gas and oxygen case showed the following points:—

1. Appearance of well-being with no undue discomfort. The chloroform and ether or ether patient showed much more collapse with pale facies.

2. The blood pressure and pulse-rate readings of the gas and oxygen patient were identical with the readings taken before operation, whereas in the others the blood pressure in every case had decreased by 10 to 20 mm. Hg, while the pulse-rate was higher by as much as 25 to 30 beats per minute.

3. The gas and oxygen patients showed little tendency to vomit and in many cases vomiting was conspicuous by its absence, whereas the other patients had considerable trouble from frequent retching.

Two Cases with Lung Complications.

Only two patients had distressful vomiting, and these were the cases which showed signs of lung complications. Both were women who had had frequent attacks of biliary colic before being admitted to hospital.

CASE 1.—A woman, aged 69, was admitted as an emergency case with acute cholecystitis. She was much collapsed and was having frequent spasms of biliary colic which were relieved by morphia. At the end of a week her symptoms had partially disappeared, while after four weeks' interval the acute condition had practically subsided and it was decided to perform a laparotomy. A cholecystogram three days previously had revealed the presence of two large stones in the gall-bladder. Under gas and oxygen the abdomen was opened by a right paramedian incision and a cholecystostomy was performed with removal of the stones; the operation took 85 minutes. She vomited at frequent intervals for four days after the operation, during which time the drainage was maintained. On the fifth day she developed a temperature of 103·5° F. with signs of congestion in the right base. On the eighth day, however, the temperature became normal and the signs in the lung had cleared up. She died on the tenth day and autopsy revealed a deep-seated subphrenic abscess with manifestations of what had been massive collapse of the right base.

CASE 2.—A woman, aged 48, had had several attacks of acute cholecystitis and was admitted in one of them. She was somewhat "chesty" and had a dilated irregularly-irregular heart. Four days later a cholecystectomy and appendicectomy were performed under gas and oxygen, the total time being 1 hour 20 minutes. Almost as soon as she returned to the ward she vomited, and this persisted at irregular intervals for three days. The day after operation her temperature was 102° F., her respiration-rate 32, and her pulse-rate 120. There were well-marked signs of a broncho-pneumonia of the right lung, from which she died at the end of the fourth day. At autopsy the right heart contained much blood clot, while the right lung showed definite patches of consolidation.

These two cases have been described because they were the only two, in a series of 165, which had any lung complications. They were both particularly adipose women; the former did not really die of a lung complication and the latter had a very bad family history. In this series there have been ten cholecystectomies, all the other cases running an uninterrupted course.

The Other 163 Inductions.

For herniæ, hydroceles, and empyemata gas and oxygen gave every satisfaction, both from the anæsthetic point of view and in the after-results, for these patients were discharged sooner than those who had had a chloroform and ether mixture or ether. In rib-resection for empyema a further advantage of gas and oxygen is that after the parietal pleura has been incised drainage is facilitated by giving oxygen under pressure.

This series includes 11 panhysterectomies performed under gas and oxygen with a good result in every case. Two cases of resection of large intestine for scirrhous stricture did particularly well, one case being discharged five weeks after operation. One particularly pleasing operation under gas and oxygen was a Cæsarean section for contracted pelvis in a woman aged 33 of particularly small build. As soon as the fœtus was delivered outside the abdominal wound the uterus almost immediately began to contract and retract, with the result that there was very little hæmorrhage. This was due to the fact that the uterus was not paralysed as it would have been under a deep chloroform and ether mixture or ether.

The only serious difficulties I have observed whilst operating with gas and oxygen are: (*a*) controlling the bowel which is apt to balloon out through the wound; (*b*) stitching the peritoneum.

The first factor is especially apparent while working in the upper abdomen or attempting to get a good field for examination of the uterus and appendages. This difficulty, however, can easily be overcome by carefully packing off the bowel with three or four abdominal towels. If this has been done methodically the bowel will give no further trouble, either in a cholecystectomy or a hysterectomy.

In stitching the peritoneum there may be difficulty in getting the peritoneum to come together, especially in an upper abdominal wound. This is greatly facilitated if, before the abdomen is entered, the skin, recti, and peritoneum are injected with 20–30 c.cm. of 0·5 per cent. solution of novocain. In most cases this is quite sufficient to give the necessary relaxation for stitching the peritoneum. Another factor which has been found to facilitate relaxation is placing a pillow under the patient's knees when he or she is put on the table, so that the hip- and knee-joints are slightly flexed.

In the clamp and ligature treatment of hæmorrhoids the previous injection of 15–20 c.cm. of a 0·5 per cent. solution of novocain into the external sphincter ani gives a beautiful relaxation under gas and oxygen and also assists in overcoming much of the discomfort from painful spasms that the patient is apt to experience in the first 8–12 hours after operation.

In all cases opoidine was given three-quarters of an hour or an hour before operation. In the majority of cases one-third of a grain only was given, but in a few cases, especially in alcoholics and heavy cigarette-smokers, two-thirds of a grain were required.

It is now agreed that, although the method requires a little extra care and patience on the part of the surgeon, such operations as a cholecystectomy or hysterectomy are not only possible under gas and oxygen, but are in the best interests of the patients.

I am indebted to Dr. E. J. Chambers (Doncaster) the honorary anæsthetist, for permitting me to publish these observations, and to the honorary surgeons for the cases.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF OBSTETRICS AND COMPARATIVE MEDICINE.

A JOINT meeting of these Sections was held on Oct. 18th, with Dr. ARTHUR GILES, President of the Section of Obstetrics, in the chair, to discuss the

CAUSES OF EARLY ABORTION AND STERILITY.

The Chairman began by speaking of the need for clear definitions. Sterility, he said, meant incapacity to conceive, and abortion should not be spoken of as a cause of sterility. A woman who had conceived at all—whether she had miscarried or not—was not a sterile woman.

Prof. ARTHUR ROBINSON (Edinburgh), in opening the discussion, said he could not accept the Chairman's definition. To speak of a man or a woman as sterile was not in accordance with the biological view of sterility. The object of fertilisation was to carry on the race, and sterility must be the opposite of fertility. He would define sterility as lack of the power of a pair to produce living young which could in its turn become fertile.

Varieties and Causes of Sterility.

Sterility might be due to injury, malformation, or disease of the genital organs. An interesting group of cases were those in which one or other of a pair was incapable of producing mature germ cells (gametes). In the male such a defect might be recognised and verified, but in the female he did not know of any way in which this could be done. In human beings menstruation was no criterion, nor was "heat" in animals necessarily so. Parkes had said that all the symptoms and signs of heat could be present in the absence of any ovarian follicles. By feeding a young animal on actual anterior lobe of pituitary it could be made precociously fertile. By feeding an adult animal with the same substance it could be prevented from producing either ova or spermatozoa. Thus by the same means one could hurry up something and also destroy the capacity to do something. This latter process might conceivably occur under ordinary conditions. If an animal could not produce germ cells there would be no abortion, but there was another group of cases in which the germ cells were mature but abnormal. In Canada Savage and Williams had tried to detect this abnormality in the spermatozoa of bulls. They had found that the heads of the spermatozoa varied in size, and that if this variation was beyond certain narrow limits the particular bull was not a good sire. Following service by such bulls there were many abortions and the progeny were, in general, poor.

Recently a good deal had been written about vitamin E, which was said to be necessary to fertility. It had been found that if female rats were fed on food deficient in vitamin E and then placed with a male, the embryos died on the eighth day of pregnancy. That was, from the point of view of the observer, the effect on the embryo or the uterus. But it might be that this E-deficient food had so affected the chromatic quality of the ovum that, although it was capable of uniting with the germ of the other sex to form a zygote, the latter was unable to live.

Another group of cases was that in which neither member of the pair was unfertile with other mates, but the two were unfertile together. He had conducted observations on a series of horses; 3040 ova were shed by thoroughbred mares, and over 58 per cent. of them failed to produce young, though the matings were carried out under the control of the Scottish Agricultural Board, and all the stallions concerned were proved to be healthy. The inquiry extended over five years. Clydesdales were also investigated, this time over a period of six years. In these, 48 per cent. of the ova produced no result, though insemination had taken place in the ordinary way, under fairly skilled observation. How could this non-fertilisation be accounted for? Commonly it was thought that under ordinary circumstances every ovum would be fertilised and so help to form a zygote which would form a new individual, but, even under favourable circumstances, only half did so. In the case of the mare, abortion might occur without being noticed. There was no close attachment of the chorion to the uterine mucosa. In Scotland no records of abortion were kept.

To experiment it was desirable to use an animal which produced several at a birth, and which was not too large. He chose the ferret. He obtained 105 which were useful for the purpose, and they produced 1040 ova; 39 per cent. of these ova failed to form living young—i.e., the results of union with living spermatozoa were dead. All the animals were kept in good condition. Animals were killed at varying stages to see what had happened. An average of 24 per cent. died in the earlier stages of gestation, 47 per cent. in the later. Very few of the spoilt ova were found dead in the peritoneal cavity. Some ova were left unfertilised, while their neighbours were fertilised. There was a uniform style of living for all the animals, and the males used were the same. Examining the ovaries of animals which did not go to term, before the rupture of the ovarian follicles, the same number of follicles was found as in other animals, and the ova were apparently the same. The only explanation he could think of was that in the chromatic arrangement of the nuclei the paired arrangement of the so-called "genes" had become disturbed, and lethal combinations of chromosomes would cause the zygotes to die after fertilisation had occurred. In some cases, however, the spermatozoa might not be able to unite with the ovum. But there was one complication which he could not quite explain. Two people married and might have no children, but if one died and the survivor remarried, that survivor might have children; and the same thing might, of course, happen after divorce. Yet he had never heard of a case in which the pair had no children but after divorce both had children by their subsequent partners. In some places it was usual for marriage not to take place until after a child had resulted from cohabitation, and if no child was to be born, the parties tried again elsewhere. As in the case of horses the spermatozoa of one male might not fertilise the ovum of a particular female. When this happened he suggested that there was an incompatibility between the germ cells of opposite sexes, so that they did not fertilise, or if they did so the arrangement of the chromatic particles was such that the zygote might die at any stage after fertilisation. The period during which it might die did not end with birth. An abortion was Nature's way of removing a failure so that the parents could quickly have another chance of mature reproduction.

Mr. J. B. BARKER preferred not to attempt definitions of abortion and sterility. In cattle the two conditions gradually merged into each other. Early abortion in these animals, showing a macroscopical abort, was rare, though early abortion was probably common. Sterility was an everyday state. A bovine abort at 31 days, with unruptured membranes, was a mass of about 20 oz. Early abortion in cattle might be due to any of a number of causes. The morula might lack power to absorb nutrient materials, or such nutrient materials might be lacking, or deleterious materials might be present. Two other possible factors were the absence of placental areas and definite disease of the endometrium. Mr. Barker regarded sterility in cattle as only a previous state to an early abortion, both being due to the same disease-causing agencies. For purposes of discussion he submitted the following causes of sterility: (1) Failure of the male to produce perfectly functioning spermatozoa (orchitis). (2) Failure of a functioning spermatozoon to reach the ovum because of vaginitis, cervicitis, endometritis, or salpingitis. (3) Failure of the ovary to produce a perfectly functioning ovum because of oöphoritis. (4) Failure of any ovum to reach a favourable position for fertilisation in the Fallopian tube owing to the presence of salpingitis.

Abortion in Man.

Prof. H. BECKWITH WHITEHOUSE said that in Germany the number of abortions each year was said to be between 500,000 and 875,000, while in 1919 one abortion for every two births took place in Hamburg. In this country investigations based on 3000 patients admitted to a gynæcological clinic showed an incidence of one abortion to every 4·7 births. The proportion of women who aborted at some time in their sexual life was about 35 per cent. The attempt to arrive at the frequency of natural abortion was vitiated by the criminal termination of pregnancies.

For gestation to proceed in the natural way it was necessary (1) that the germ plasm of the oöcyte and the spermatozoon should have sufficient initial vitality; (2) that the zygote should be implanted in a position favouring its subsequent development; (3) that the nutrition of the ovum should be maintained. The natural site of attachment of the zygote was the decidua of the upper uterine segment. Many abortions after the twelfth week seemed to be associated with a low placentation in the region of the os internum. It was difficult to get direct evidence to show that defective vitality of germ cells led to premature death of the fertilised ovum. Of 1233 women 336 were childless, 71 of them having aborted. Of 158 women who had one child 64 aborted. A number of factors might be operative.

A woman, aged 33, was married for five years and was delivered of a dead child at the seventh month of her first gestation, though no cause was apparent. The Wassermann reaction in both husband and wife was negative. She was a small woman, a seven-months child, and was the last of a family of 13. Her mother also was a premature child, and was the last of 16 children; also all her immediate brothers and sisters had been premature. These people showed a succession of lack of reproductive vitality. An abnormal implantation of ovum in the uterus nearly always led to disaster. Implantation in the decidua was commonly followed by death of the ovum. When abortion took place at the twelfth week it was commonly attributed to a low deposition in the os internum.

The development and function of the decidua called for special consideration. Its growth depended on a hormone which was elaborated in the corpus luteum; hence lesions in the ovaries might account for many of the early abortions which were associated with uterine fibroids, displacements, &c. The Graafian follicle and corpus luteum were liberally supplied with nerve elements, and so inhibition of the latter might be the cause of the "reflex abortion" which followed mental or physical shock. Half the ova aborting during the first three months of gestation appeared to be pathological, and the view of embryologists was that pathological ova were the result of an abnormal environment, and not of any inherent factor in the germ cells. In the case of the eggs of certain fishes, sea-urchins, frogs, &c., it was possible, by using certain solutions, to produce from normal cells every form of anomaly occurring in man, such as spina bifida and anencephalus. Hence it was likely that abnormal food factors and various toxins might form an important element in causing obscure early abortions. In the raising of animal stock and in egg production the importance of iodine was receiving ever-widening recognition. An adequate supply of calcium was equally important. The work of Evans and Burr on a specific antisterility food factor, vitamin E, promised a new field of investigation concerning the causes and treatment of repeated abortion. In a series of 300 cases investigated, said Prof. Whitehouse, in 58 (19 per cent.) the cause of the abortion was not known, 30 were due to prolapse, 21 to fibroids, 23 to metritis, 29 to salpingitis, 14 to retroversion, 10 to ectropion, 5 to cystomata, 9 to toxæmia, and 9 were criminally induced.

Contagious Abortion.

Mr. O. STINSON did not doubt that in cattle abortion was mostly due to the bacillus of Bang. In nearly every case this organism found its way into the alimentary tract and was not conveyed by the act of coitus. It caused a very serious state of things. At present 50 farms were affected by it in his province, and in some it had been active three or four years. Gradually, on any particular farm, the activity of the bacillus became reduced. On farms where abortion was rife many cows proceeded to full term, but never fully held again; they did not abort, but afterwards were sterile, though duly served by the male. Early abortion occurred among cattle with fair frequency. The later the abortion the greater was the liability to sterility. In some regions, said Mr. Stinson, there was a deficiency of calcium and iodine in the food, and the cows only conceived in July, August, and September. During the last two years he had been doing work on calcium deficiency and sugar deficiency, and he had arrived at the conclusion that there was a definite association between abortion and sterility on one hand, and calcium, iodine, and sugar deficiency on the other. Much had been said about giving insulin in diabetes, but little was said of the possibility of too much insulin being present in the organism. In cases of abortion he thought there was usually an upset of basal metabolism, or of the secretion of the endocrine glands.

Captain S. R. DOUGLAS, F.R.S., pointed out that in human abortion infection was seldom mentioned as a cause. A Copenhagen authority reported that there was an outbreak of *B. abortus* fever among women in Denmark—500 cases in the year. Among the cases were eight pregnant women, seven of whom aborted. It must have been passed on from the cow to man. He asked whether there might not be other organisms which had the same effect in the human —possibly including Malta fever. If material were taken from the uterus immediately after abortion and examined, some bacterial cause for the mishap might be discovered.

Mr. LESLIE PUGH said that of the cows affected with contagious abortion, about 30 per cent. passed the bacillus out into their milk. He therefore supported Captain Douglas's plea for bacterial search in these cases. The Bang bacillus affected only sexually mature animals. If young animals responded to it, it would probably lead to the end of the disease, because of the immunity to it which would be set up.

Dr. S. FORSDIKE said that on expressing the contents of the corpus luteum by squeezing the ovary, the cow was enabled to become pregnant at the next service.

Mr. A. L. SHEATHER, D.Sc., confirmed Dr. Forsdike's statement. He had done that operation a hundred times; it was easily done by manipulation per rectum. Abortion δ-12 hourse four days later, and the cow couldr all cases opoidiF served afterwards. Surgical hour or an hour befos of the cow. In many cases of cases one-third of aver he felt that the infection ses, especially in aF handling by physician or rs, two-thirds of a gus had been there all the time; such autogenous infection was found in bitches and cows which had not been handled at all.

The CHAIRMAN suggested that when a woman aborted at a stage when she already had mammary secretion it might be worth while to make a careful examination of her milk.

SECTION OF MEDICINE.

AT a meeting of this Section, held on Oct. 22nd, the chair was taken by the President, Dr. R. A. YOUNG, and Dr. W. J. ADIE opened a discussion on

DISEASES OF THE PITUITARY BODY.

The common tumours, the adenomas of the anterior lobe, were classified, he said, according to the staining of their cells, but much confusion had arisen around the terms used. He would therefore employ the names "acidophile" and "basophile" for the cells with granules that stained red or blue with, for instance, Mallory's acid fuchsin anilin-blue, and "indifferent" for the agranular principal cells, the Hauptzellen, that hardly stained at all, and he would speak of the tumours as granular or agranular. The tumour associated with acromegaly was usually a simple granular adenoma of the anterior lobe with acidophile cells; sometimes, however, the cells were basophile or mixed. The cells seemed to be more often basophile in acromegalics who had become obese or cachectic, but no rigid formula could be used for associating the character of the cells with the symptoms. The signs of acromegaly appeared before the tumour was large enough to deform the sella and were almost always very obvious before it began to cause visual or other pressure symptoms. This fact had given rise to a dangerous and erroneous impression that a tumour of the pituitary body was necessarily accompanied by endocrine signs; the commonest form of tumour might actually be very large and cause failure of vision with no glandular signs or with very slight ones. Persistent glycosuria occurred with granular adenomata only—i.e., in giants and acromegalics. In many ways it resembled pancreatic diabetes but ran a variable course. Acromegaly might remain stationary for years, or the headaches and malaise might cease although the body continued to grow. In these cases operation could not be recommended, although delay increased the danger. Should operation be performed in the earliest stages in order to prevent deformities? At present it was only done to relieve headache and conserve vision; early operation might hasten the inevitable cachexia. At present it did not seem justifiable to operate for glandular disturbances only. X ray treatment should always be tried in acromegaly, though it was little use in other forms of tumour. Radium had not given good results.

Adenoma of the anterior lobe without acromegaly was the commonest and most important tumour. It was almost exclusively confined to adults and was agranular. The cardinal sign was loss of vision; there might be nothing else. This condition provided one of the few opportunities of saving sight by prompt operation, but it was often lost through failure of early diagnosis. In most cases there was a tendency to adiposity with smooth, pale, soft skin, scanty hair, amenorrhœa or diminished potency, pale optic nerves, bitemporal defects, headaches, and enlargement of the sella turcica, but endocrine disorders might be absent and the sella might be normal. Pituitary tumour should be suspected in every case of failing vision, even when some other cause seemed to be present; toxic amblyopia was diagnosed too readily. A pituitary tumour might cause loss of tendon reflexes and pains in the legs, so that every apparent tabetic optic atrophy should be scrutinised very carefully; the Argyll Robertson pupil confirmed a diagnosis of tabes.

Tumours arising from the remains of Rathke's pouch were third in order of frequency, and were the only tumours to produce symptoms before the age of 15. The patient would be an intelligent and cheerful child with gross signs of endocrine disorder, suffering from headaches and failing vision, swollen discs, bitemporal defect, and a deformed sella with shadows above it. Failing vision, however, might appear at any age in patients free from endocrine symptoms, and in adults the typical picture might be absent. The ultimate prognosis was bad.

The symptoms in these cases fell into two groups: those due to intracranial pressure and those due to dysfunction of an endocrine gland. A typical symptom was diabetes insipidus, about which there had been much controversy. Polyuria might occur when the lesion was confined either to the posterior lobe of the pituitary body or to the hypothalamus. The gland and the adjacent centres acted together as a neuro-endocrine mechanism, and this was probably true for all the symptoms associated with disease of this region. How the mechanism acted, whether it was nervous or hormonal, we did not know. Since injury to the tuber could produce polyuria although the gland was intact, the nervous centres seemed to be predominant. Moreover, injury to the tuber produced polyuria when the gland had been removed and the kidneys completely denervated; apparently a lack of the nervous impulses conveyed from the periventricular nuclei to the medulla and by the splanchnic nerves caused metabolic disturbances in the tissues. The diabetes insipidus of pituitary disease was milder and associated with less desiccation and emaciation than that of midbrain disease. Polyuria was certainly not a simple symptom but the complex sum of a number of disturbances of simpler functions of vegetative centres. Until we knew more of the metabolism of water we could not solve the problems of growth and metabolism.

Mr. NORMAN DOTT reviewed a number of cases which illustrated the types of disorder, the nature of treatment, and the results. These included examples of simple hyperpituitarism in the child and in the adult, eosinophile hyperpituitarism associated with acromegaly, pure visual disturbance, and a combination of visual with other symptoms. There seemed to be some evidence, he said, that the eosinophile cells were connected with growth and the basophile cells with sexual ability.

Pathological Examinations.

Prof. E. C. DODDS called attention to some methods of investigating pituitary disease. Giant animals could be produced by injecting extracts of the posterior lobe of the pituitary into the peritoneal cavity. The extract of the anterior lobe stimulated the ovary to produce œstrin and, if it were injected into an immature female mouse, puberty would occur in 50–60 hours—i.e., the vagina would open and œstrus appear. In the mature animal the effect was to produce continuous œstrus for a few days, after which the ovary became exhausted and œstrus would be inhibited as long as the anterior lobe extract was continued. This might explain the amenorrhœa associated with pituitary tumour. In the very early stages of pregnancy there was a sudden discharge of anterior lobe hormone into the urine. If the urine of a pregnant woman were injected into mice the ovaries would be found studded with corpora hæmorrhagica, which was a definite sign of pregnancy. Anterior lobe transplants into an immature male produced puberty with descent of the testes and spermatogenesis.

Dr. O. LEYTON described experiments with various proprietary preparations of pituitary which were found to have very different effects on diabetes insipidus, although all contained a standard number of units of oxytocic substance. The best results were obtained from freshly killed animals; delay for even an hour weakened the action, as did also filtration. The work had led on to the separation of the vasopressor from the oxytocic substance. He believed that many cases were due to an increase of sugar in the blood without any great alteration [illegible] the power of utilising sugar.

Epithelial Tumours in the Pituitary Region.

Dr. MACDONALD CRITCHLEY reviewed the embryology of the pituitary and said that epithelial tumours were of two kinds: those growing from primitive remains in Rathke's pouch, and those growing from relics of the old cranio-pharyngeal duct, which were found in 80 per cent. of adult brains. The first were rare and simple, situated in or just above the pituitary. They were described as having a ciliated or columnar lining, but in his experience it was exceptional to find ciliated or columnar epithelium either in Rathke's pouch or in the tumours. The second group were of three kinds: (1) the rather rare simple papillary cysts which might show cuboidal or transitional epithelium several layers thick; (2) the common adamantinomata, characterised by a single peripheral layer of columnar cells in palisade formation bounding epithelial masses rather like the prickle cells of the skin. The sections resembled those of adamantinomata of the jaw, and commonly showed secondary keratinisation, calcification, or even ossification, which caused suprasellar shadows in the X ray; (3) spinal-celled carcinomata which were malignant and very rare, only five cases being on record. It was just possible that there was another type, arising from the infundibular recess and not derived from epithelium.

The Surgical Differential Diagnosis.

Mr. HUGH CAIRNS reviewed the conditions which might resemble pituitary tumour. While the physical changes of acromegaly were usually unmistakable, he said, he had known one case of hypertrophic pulmonary osteo-arthropathy mistaken for pituitary tumour. In acromegaly the overgrowth was not limited to the extremities; the tongue and vocal cords were also involved. Occasionally an acromegalic might have a normal sella turcica as the adenoma grew up into the diaphragma sellæ; this produced a scotomatous type of hemianopia, liable to sudden and rapid failure of vision. Fröhlich's syndrome was often mistaken for pituitary disorder. Cysts of Rathke's pouch were more often confused with tumours of the fourth and hinder end of the third ventricle; X rays showed typical calcification in 75 per cent. of cases. There was usually no calcification in suprasellar endothelioma or meningeoma, but the symptoms were bitemporal hemianopia and optic atrophy without endocrine disorder or distortion of the sella. Glioma of the optic chiasma led to optic atrophy and occasionally to defects in the visual fields, obesity, polyuria, and polydipsia; there was a pear-shaped prolongation of the sella into the optic foramina, which might also be enlarged, and the visual disturbance was out of all proportion to the changes in the discs. The patients were young and often showed brown spots on their skin. Glioma of the third ventricle caused obesity, polyuria, and polydipsia, but papillœdema appeared early. Cerebral aneurysm might cause difficulty in diagnosis and a tumour in the fourth ventricle might cause a dilatation in the third, which pressed on the sella and caused symptoms such as amenorrhœa, purely as a result of pressure.

Pituitary Dysfunction and Mental Disorder.

Dr. F. A. PICKWORTH described work on the relationship of infection of the sphenoidal sinus to disorders of the pituitary and brain substance. Organisms had been demonstrated within the pituitary in these cases. Resistance to the spread of infection from a septic sinus was offered by the sinus membrane and the capsule of the gland much more than by the intervening bone. A large deposit of colloid in the gland indicated previous adjacent sepsis, the normal amount of colloid averaging about 1·2 per cent. Endocrine disturbances were a marked feature among mental hospital patients, and Dr. Pickworth suggested that they were due to endocrine imbalance following pituitary disturbance after infections of low-virulence, which spread very slowly along ly.

or thrombosed vessels. The symptoms varied according to the age and the stability of the other endocrine glands of the body.

Dr. T. C. **GRAVES** described two typical cases of pituitary disorder associated with sphenoidal sinus sepsis. The usual symptoms were general loss of muscle tone; disturbance of the peripheral circulation, causing extreme pallor and cyanosis of the extremities; disturbance of nutrition, with striking emaciation which might be followed by obesity; and disturbance of the reproductive mechanism, with amenorrhœa. An interesting feature was complete absence of pyrexial response to the injection of vaccines such as TAB, although the pulse-rate went up in the usual way. A large number of such cases had been collected and had improved after suitable rhinological treatment.

Dr. **BERNARD MYERS** referred to the importance of blood pressure, and Dr. **ADIE** briefly replied.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(*Continued from p. 826.*)

SECTION OF RADIOLOGY AND RADIOTHERAPEUTICS.

DEMONSTRATIONS.

FOUR demonstrations were arranged in connexion with this Section.

Cinematography of the Living Cell.

Dr. R. G. **CANTI** preceded this demonstration by a brief explanation of the technique employed in making the films. It was found that the study of growing tissues under the microscope by ordinary methods entailed an enormous number of personal observations. Not only was the work very fatiguing, but, since only fairly well-marked cell changes were sufficiently striking to excite attention during the comparatively slow progress of growth in tissue culture, the events leading up to the change were not noted. Cinematography provided a means of recording changes too small to be appreciated by the eye directly. Also, by securing cinema pictures at intervals varying from 3 to 60 seconds and projecting them at the normal rate of 16 per second, the processes which occupied many hours in occurring could be "speeded up" and shown as if they occurred in a few minutes. The actual "speeding-up" effect varied between 50, 120, 480, and 960 times. Elaborate precautions were taken to prevent vibration affecting the apparatus. The cultures photographed consisted of periosteum of chick embryo of 6–8 days' incubation, and of portions of tumour of Jensen's rat sarcoma, each in a suitable medium. Three reels of film were shown.

Reel 1.—After preliminary views of the explant upon its microscopic slide, to give an idea of the size of the fragment used, a cinema film of the edge of the living culture was shown on which the events of 27 hours were "speeded up" 960 times. Fibroblasts, wandering out at the culture-edge, rapidly gave it a fluffy appearance, whilst ahead of the fibroblasts a zone of rapidly moving wandering cells was strikingly shown. Following this, a picture at higher magnification clearly showed the stages of cell division, the daughter cells moving away in opposite directions. Next a hand was shown drawing a diagram of a vegetable fibroblast, to be replaced by an actual photograph at high magnification of the cell itself, in which the nucleus, nucleoli, and fat globules were clearly visible. Similar pictures showed amœboid movements in a wandering cell, with its fine pseudopodia. High magnification views of cell division followed, in which the details of mitosis were seen.

Reel 2 showed the effects of irradiation upon the same cells, the source of irradiation being radium emanation contained in small glass tubes. After a period during which normal cell activity was proceeding, the commencement of irradiation was marked by a "black-out" of the picture. The first pictures showed irradiation of chick embryo periosteum, and was "speeded up" 480 times. Cell mitosis and the spreading of the growing edge appeared to cease instantaneously. Very soon the wandering cells assumed a spherical form, and after a moment the fibroblasts contracted down into irregular spheres and showed the "bubbling" characteristic of breaking-down cells. Several records of similar experiments at different speed and magnifications were shown. The remaining pictures recorded the effects of irradiating Jensen's rat sarcoma, in which the same arrest of movement and cell division, assumption of spherical shape, and commencing breaking-down were demonstrated. The action of irradiation of the intensity used showed the following points. Fibroblasts of normal periosteum, though rendered immobile, showed very little structural change after exposure. Very few became rounded or broke down. Wandering cells all showed a marked effect after 20 minutes' exposure; movement ceased, and the cells became rounded, and their outline blurred. If a cell was dividing the process ceased at once. When the cells of Jensen's rat sarcoma were irradiated, all types appeared to be affected, whether mobile or fibroblastic in type. These experiments of direct observation appeared to substantiate the hypothesis of selective action upon malignant cells.

Reel 3 showed direct cinematographic film of living cells under dark-ground illumination. The cells shown were the vegetative fibroblasts of the choroid of the chick embryo in 2–3 days' culture. Cell structure and movement were shown with extraordinary clearness. Only cells which are flattened out between coverslips and radium, and which remain in one optical plane, are suitable for this method.

Living Cells in Tissue Culture.

A demonstration of living cells in tissue culture was given in the Manchester Royal Infirmary by Miss S. F. Cox and Dr. F. G. Spear. They showed living cells as seen with dark-ground illumination and cell division in living cultures. They also gave a demonstration of stained specimens and charts showing the effect of various physical agents on cells cultivated in vitro. These agents included hard beam X rays, soft beam X rays, radium, radium emanation, and cold.

Cases Treated by Radium.

A demonstration was given in the out-patient department of the Manchester Royal Infirmary consisting of 103 patients who had previously been treated with radium by the Manchester and District Radium Institute. The patients were demonstrated by Dr. G. E. Birkett, Mr. W. R. Douglas, Mr. A. Graham Bryce, Dr. O. Chance, Mr. A. H. Baker, and Mr. K. H. Watkins. They included 73 cases of carcinoma of the buccal cavity, mostly treated between 1925 and 1928; it was noticeable that there is practically no impairment of function following radium treatment. As the result of the experience gained during the last few years, the technique is now almost standardised, and consists of implantation of needles of low linear intensity (0·66 mg. radium element), screened by 0·6 mm. platinum for 8 to 12 days. The importance of an adequate active length (10–20 mm.) was emphasised. The treatment of the lymphatic drainage area in these cases by radium alone is not yet on a satisfactory basis, and where glands are palpable block dissections had been performed. These involve the removal of the sterno-mastoid muscle and internal jugular vein. As a rule implantation is carried out in the neck at the same time.

Eight cases of carcinoma of the breast, treated by implantation of a large number of separate foci into the primary growth and the lymphatic drainage area, were also shown. In such cases the axilla is exposed, so that the implanted units can be placed in position accurately. The remaining 22 patients had had cancer of various types, but chiefly epitheliomata and rodent ulcers of the skin. Some of them showed clearly that rodent ulcers involving the eyelids can be successfully treated without damage to the globe and with a perfect cosmetic and functional result. The implanted units in these cases, and the cases of carcinoma of the breast, were of the same linear intensity as are used for the treatment of buccal carcinoma.

Functional Studies of the Tracheo-bronchial Tree.

The "cin-ex-camera" is the term applied to a new apparatus designed by Dr. William A. Hudson and Dr. Hans A. Jarre (Detroit, U.S.A.). It is designed for the purpose of making successive X ray pictures on film bands at short enough intervals to permit of the interpretation of the functional changes occurring in the organ being studied. The apparatus will make up to five records per second, and will handle a film band up to 80 ft. in length. The width of the film band can be varied. The method of procedure in the studies of the tracheo-bronchial tree which was demonstrated was the passage of a small soft rubber catheter, with the aid of a direct laryngoscope through the glottis into the bronchus, under cocaine anæsthesia of the glottis. Through the catheter lipiodol was allowed to flow into the bronchi. Records were made at the rate of from one to four exposures per second. Studies were reported on five individuals:—

1.—A healthy young female, in whom there were noted: (*a*) Regularly occurring narrowings of the bronchi, which seem to originate in the peripheral bronchi, and seem to be associated with the propulsion of the oil toward the main stem bronchi. These narrowings occur regularly during expiration. (*b*) The fact that the angles at diverging bronchi are greater during expiration than during inspiration. (*c*) Evidence of rotation of the lung field is seen. (*d*) A measurable shifting of the bronchial tree downwards during inspiration is present. (*e*) A shifting of the bronchi closely simulating the opening and closing of a fan. (*f*) The fact that a suppressed cough can force material into the alveoli, but during quiet breathing no oil enters the alveoli.

2.—A male, aged 58, with a moderate degree of emphysema revealed definite narrowings of the bronchial tree, which definitely progress toward the main stem bronchus. This phenomenon is very similar to a peristaltic wave. The other observations made in case 1 were also noticeable. In addition it was noted that in an emphysematous lung the lipiodol flows into the alveoli very readily, this being attributed to an enlarged atrial opening.

3.—In a case of long-standing bronchiectasis no evidence of motor activity in the involved bronchi could be seen.

4 and 5.—In two cases of asthma the bronchi were found to be in a continual state of bronchial spasm, in fact the lipiodol did not enter the terminal bronchioli. In addition, areas of temporary spasm were observed.

The authors believe that there is a definite motor phenomenon in the tracheo-bronchial tree. This phenomenon is inhibited in cases of long-standing infection of the bronchial tree, but is hyperactive in cases of an asthmatic nature.

SECTION OF MEDICAL SOCIOLOGY.

VALUE OF HEALTH PROPAGANDA.

THREE papers written (1) from the point of view of the administrator by Prof. F. E. Wynne (Sheffield), (2) from that of the practitioner by Dr. H. C. Jonas (Barnstaple), and (3) from that of the press by Mr. H. A. Gwynne (President of the Institute of Journalists) had been circulated beforehand amongst the speakers invited to join in this discussion.

Prof. WYNNE adopted the rôle of *advocatus diaboli* as regards the claims to canonisation of propagandists other than workers in the statutory health services, and thereby gave zest to the discussion. Propaganda, he said, was a horrible word, and one of the unpleasant things popularised by the war, during which it came to mean "a competitive effort, in misleading the public of the particular nation concerned." It was, he said, essentially associated with the vulgarity which is an integral part of all successful advertisement. Public health propaganda and education had become the latest duty imposed upon local authorities, though much work of this kind had been done by voluntary organisations, the multiplication and overlapping of which had become, in his opinion, almost a public scandal. He thought the Minister of Health might be empowered to register these associations, to reduce their number from about 800 to 8, and to refuse registration to new competitors in this field. Whatever methods of propaganda were adopted, nothing should be done or said to accentuate that morbid absorption in his, or her, own health on the part of individuals, which is one of the worst vices of our time. The available methods were—public lectures, instruction in the schools, the distribution of special literature, and the judicious use of the public press. "Health weeks" could be organised so as to have an educational value, but might degenerate into mere stunts, without any lasting effect. Teaching of hygiene in schools ought to be valuable, but at present he was afraid it was not. In his experience the teaching given was, with few exceptions, perfunctory and in the wrong hands. Public lectures in large halls were of doubtful value, but lectures to small audiences, followed by questions and developing into discussions, were really educational. Most of the special literature which was submitted to him found its way to the waste paper basket, but he had found the magazine *Better Health* useful, and it was the only publication, apart from local leaflets, distributed by his department. As regards the use of the press, medical men were restrained by the rules very properly laid down by the General Medical Council, but could contribute articles on matters which they believed to be of public importance as from "a medical correspondent." He thought it was most important that the public should be kept in touch with the progress of medical science by wise and well-informed contributions to the press. Dr. Wynne concluded that the most important work done in the propagation of knowledge about health matters was that which was being done daily and persistently by our public health departments, their sanitary services, their maternity and child welfare services, their school medical services, tuberculosis services, and other sections of their activities; of these the public knew little, but they derived more benefit from them than they ever would from any much-advertised "propaganda."

Lord LEVERHULME said that he was intimately concerned with advertisement, but that he did not agree with Dr. Wynne that in order to be successful it must be vulgar. Industry was becoming increasingly interested in health matters. The periodical medical examination of employees had been suggested but was, at present, negatived, partly owing to the expense and partly owing to suspicion as to its object. The medical profession were unable to supply the signed articles which the press would prefer, and the profession could not help to advertise proprietary articles, although this would be useful to the public.

Dr. JONAS began by stating that he had taken some trouble to ascertain that the views expressed in his paper were generally approved by his brother practitioners. He went on to criticise the flimsiness of the evidence on which our population was alleged to be C3. The most promising sign about the present health campaign was the stress laid on the education of the young. To teach healthy habits to the young was valuable, but to make the young think about their health implied failure. Dr. Jonas singled out for unqualified praise the Boy Scout and Girl Guide movements and the National Association for the Provision of Playing Fields. The method of propaganda adopted must not manufacture valetudinarians, or make people introspective. The search for health was not an aim in itself but only a means to a useful life. He was opposed to the circulation of cancer leaflets. Much good health propagandism was accomplished daily by the great body of general practitioners, especially by engendering in their patients a cheery optimism.

Mr. GWYNNE said the press was only too anxious to march side by side with medicine in the fight for public health. They were up against the strict rules and regulations of the medical profession. They were able to obtain an article from the best specialist on a particular subject, but it had to be published as "from a distinguished Harley-street specialist." He suggested that the British Medical Association might well examine this matter and see whether it could not evolve a solution of the difficulty and thus bridge the gulf between publicity and reticence.

Propaganda from the Public Health Services.

Mrs. E. D. SIMON (chairman of the School Inspection Subcommittee, Manchester) referred to the work of the school medical services, not only in caring for the children, but also in educating the parents. The general practitioner only saw his clients when they were ill, but the school medical officer saw them when they were well and the beginnings of illness. There was now very little opposition among the parents in Manchester to the recommendations of the service. The dislike to dental treatment was being gradually overcome. As a preliminary to immunisation they must first explain the scheme to the teachers and subsequently to the parents. Propaganda by the school medical service was continuous, not spasmodic. It reached the bad and careless parents as well as the interested parents. It did not preach only to the converted like many public lectures and meetings.

Councillor WRIGHT ROBINSON (Manchester) thought the reports of medical officers of health were powerful agents for good, although they might be read only by influential people.

Lieut.-Colonel F. E. FREMANTLE, M.P., spoke in high praise of the voluntary associations, and pointed out that much coördination of these bodies had already been effected.

Dr. VEITCH CLARK (M.O.H., Manchester) thought the day by day work of the public health services, especially with the mothers and children, was the best form of propaganda. The lectures which brought the best results were those which were given at boys' clubs and similar places, sandwiched in among other items of a programme. Posters, he thought, were frequently indiscreet and lacking in earnestness or dignity.

The Press and the Medical Profession.

Mr. H. D. NICHOLS (President of the National Union of Journalists) thought this discussion under the auspices of the B.M.A. was a sign of the times. He believed that personal hygiene would become more important in the future. The only effective help given by the medical profession to the press at present was through the medical officers of health. It was high time that the medical profession as a whole should improve its publicity organisation, with a view to supplying orthodox and authoritative information.

Dr. H. B. BRACKENBURY admitted that he had been responsible for the wish that the hundred voluntary health societies should be scrapped and a single organisation formed. He caused some amusement by suggesting that Dr. Wynne might take upon his shoulders the unifying process. Dr. Brackenbury considered that the teaching of personal and domestic hygiene in the schools was one of the best methods of propaganda and that the general practitioner also had great opportunities.

Dr. WHEELER HART (Stretford) deprecated the alarming methods of propaganda adopted with regard to cancer tuberculosis and childbirth mortality. He had been 30 years in practice and welcomed education of the public in health matters but they must be careful not to make hypochondriacs.

Miss NORAH MARCH pointed out that the voluntary workers and associations had given the lead, which was subsequently followed by the Ministry of Health and the medical officers of health, and that in the penal clause of the Local Government Act, 1929, the status of these associations was given recognition.

Dr. EUSTACE HILL (Durham County) spoke very emphatically as to the value of the work accomplished by voluntary organisations and well-organised "health weeks." He was confident that the press could help much more and on better lines than at present.

Replies.

Lord LEVERHULME said they must have propaganda on health matters. The public could be led but could not be driven. The Daylight Saving Bill was an example of subtle persuasion.

Dr. JONAS thought the problem of coöperation between the medical profession and the press was almost insoluble, while Mr. Gwynne was slightly less pessimistic.

Reviews and Notices of Books.

COLLAPSE THERAPY IN PULMONARY TUBERCULOSIS.

La Collassoterapia nella Tubercolosi Polmonare e nelle Lesioni Distruttive del Polmone. By Prof. UMBERTO CARPI, Senior Physician to the Ospedale Maggiore, and Professor of Clinical Medicine at the Royal University of Milan. Ed. Cooperativa Farmaceutica. 1929. Pp. 268. L.40.

Prof. Carpi is an ardent disciple of Carlo Forlanini, who in 1880 brought to the notice of the medical world a method of treating phthisis by artificial pneumothorax. In a foreword on the historical side of the question he claims for his master absolute priority, although admitting James Carson, who wrote in 1820 "On the Elasticity of the Lungs," as one of the precursors. Prof. Carpi is also a supporter of M. Ascoli, who with Parry Morgan in this country has explored the use of partial bilateral pneumothorax when lesions are present on both sides of the chest. Indication for this form of therapy has been extended from phthisis to various forms of pleuro-pulmonary diseases, including hæmoptysis, pleural effusions, dry pleurisy, bronchiectasis, gangrene, and bullet wounds of the thorax. After an extensive explanation of these indications, the various forms of apparatus for artificial pneumothorax are described and illustrated, including the original instrument of Forlanini and that of Prof. Carpi himself. The advantages claimed for this instrument are that it acts by air displacement, has a working capacity of 100 c.cm., while its potential capacity is unlimited. It is very sensitive; a cylinder and piston act as an index of decompression or over-pressure in the pleural cavity. It accurately measures the amount of gas injected, and the quantity injected with each respiration can also be measured. The volumetric capacity of the pleural cavity can be ascertained by the measurement of the quantity of gas spontaneously aspirated, and it acts as well in the first production of pneumothorax as in the refillings carried out at a negative pressure. The instrument is easily sterilised, every part being detachable and capable of being washed in alcohol and ether. In a chapter on the physical signs found in artificial pneumothorax, Prof. Carpi draws attention to the area of hyper-resonance found in the opposite paravertebral region, which he attempts to explain. Just as happens in effusions, when the pleural sac, distended by fluid, is displaced towards the healthy side, so in pneumothorax the mediastinal pleura, owing to the tension of the gas, becomes a sac, which is pushed in front of the vertebral column and easily overlaps the middle line. The zone of hyper-resonance thus corresponds to the shape of the pleural cavity, and is more pronounced where the mediastinal pleura yields most—i.e., in the postero-inferior section, the so-called *recessus pleuræ*. In a chapter on the clinical practice of artificial pneumothorax some importance is attached to hypotensive pneumothorax as a therapeutic means of election. The efficacy of a pneumothorax at low pressure is subject to the condition that the lung is free from adhesions at the site of the focus. In such conditions the gas introduced even in lessened amount into the pleural cavity exerts its action on the lung in a measure proportionate to the elastic tension at the surface. Now the elastic tension is naturally diminished, if not abolished, at the site of destructive pulmonary foci, and on them the gas introduced exercises an almost selective action, even if it does not do so en masse on the whole lung.

Prof. Carpi notes that bilateral localisations in the region of the apex and hilus are those which best lend themselves effectually to this method, provided that with a moderate hypotensive pneumothorax there is sufficient expansion left in the free pulmonary bases. The force of the pulmonary elastic tension is at its minimum in the region of the hilus, weak at the apices, and greatest in the bases and edges. Small amounts, therefore, at a low tension, are sufficient to neutralise those foci which are situated in the apex and hilus, and hence recent caseous lesions with a progressive tendency, and free from pleural complications, lend themselves best to the method of bilateral pneumothorax. There is much interesting and practical material in Prof. Carpi's book which will well repay the serious attention of those who are experts in collapse therapy.

FRACTURES AND DISLOCATIONS.

Treatment of Fractures and Dislocations in General Practice. Third edition. By C. MAX PAGE, D.S.O., M.S. Lond., F.R.C.S., Surgeon to St. Thomas's Hospital; and W. ROWLEY BRISTOW, M.B., B.S. Lond., F.R.C.S., Surgeon to the Orthopædic Department, St. Thomas's Hospital. London: Humphrey Milford, Oxford University Press. 1929. Pp. 284. 14s.

THIS book deals with the treatment of fractures and dislocations in clear and simple language. It is well illustrated, and provides just the kind of work that those who have to deal with fractures in general practice need for ready reference. No attempt is made to discuss a variety of ways of treatment for any individual fracture, but the methods selected are sound. The comparatively small size of the book is one of its chief attractions, and we hesitate to make any suggestion which, if adopted, might increase its bulk. It is necessary to say, however, that in future editions fractures of the ankle should be allotted more space; a classification based on the mechanism of their causation is more likely to give the reader a clear conception of these injuries and to enable him to follow the mechanical principles of their treatment.

This book should be in the possession of every medical student and general practitioner in the country.

SURGICAL PATHOLOGY.

Second edition. By WILLIAM BOYD, M.D., M.R.C.P., Professor of Pathology, University of Manitoba; Pathologist to the Winnipeg General Hospital. London and Philadelphia: W. B. Saunders Company. 1929. Pp. 933. 48s.

THE second edition of Prof. Boyd's Surgical Pathology has been generally revised and in parts rewritten. The chief changes are to be found in the chapters dealing with the stomach, the thyroid gland, and with malignant disease, especially in relation to tumours of bone, the testicle and the kidney, and the gliomata and melanomata. Many other sections have been recast so as to include new matter which has emerged since the first edition was published four years ago. All these changes have been carried out with judgment. Prof. Boyd's attitude towards disputed points is sane and critical; his discussions of the ætiology of malignant disease and the relation of gastric carcinoma to ulceration, for example, are admirably balanced; and the book as a whole may be recommended as a sound presentation of surgical pathology. There are 130 new illustrations, including a number of radiological ones, and several of the older figures have been replaced by others.

COMMUNITY HYGIENE.

By DEAN FRANKLIN SMILEY, A.B., M.D., Medical Adviser and Assistant Professor of Hygiene in Cornell University; and ADRIAN GORDON GOULD, Ph.B., M.D., Assistant Medical Adviser and Assistant Professor of Hygiene in Cornell University. New York: The Macmillan Company. 1929. Pp. 350. 8s. 6d.

THIS is not a text-book, neither can it be classified with the popular books on health, since it is primarily intended for those preparing to fill a position in society which will involve responsibility for the life and health of others. Beginning with a short section on the history and development of modern public health work the author proceeds in simple terms to discuss the common sources of infection in man, and how best they may be avoided. The effects of the weather, the air, and sun on health, and the sanitary significance of the soil, good water, clean food, and adequate housing are next dealt with. Sections follow on such important community problems as mental hygiene, sex hygiene, tuberculosis, heart disease, and cancer. A strongly-worded warning on the need for guarding against quack remedies for cancer is included.

As an example of the improvements brought about in recent years in the health of the public by means of well-conducted schemes of hygiene, the sections on maternity and child welfare and on school medical work make interesting reading. The authors rightly emphasise the importance of the educative side of this work and the need for closer coöperation between health authorities and the community. Technical terms are avoided throughout and the work provides a general survey rather than a detailed study. Those wishing to make a deeper study of health problems will find an excellent guide in the numerous references supplied.

College students of all classes, teachers, and large numbers of the public interested in the welfare of the community will like this book. The medical student entering on his public health course would do well to read it, for it puts before him from the popular standpoint those problems which health authorities throughout the world are intent on solving.

SQUINT.

Its Causes, Pathology, and Treatment. Sixth edition. By CLAUD WORTH, F.R.C.S., Consulting Surgeon to the Royal London Ophthalmic Hospital (Moorfields). London: Baillière, Tindall and Cox. 1929. Pp. 240. 10s. 6d.

MR. WORTH's book on squint, first published in 1903, deals with the ordinary concomitant squint of children, not with the paralytic variety. In the preface to this new edition the author contrasts the treatment received 30 years ago by the average case of convergent squint with that received by a similar case to-day. There can be no doubt that the modern treatment of forcing the squinting eye to function by occluding or atropinising the good eye has great advantages over the older practice. Formerly when correcting glasses had been prescribed, the ophthalmologist took no further steps to prevent the good eye from continuing to do all the work. Thus the habit of suppressing the image in the squinting eye became so firmly established as to be permanent and incapable of alteration. The author claims to have proved that the amblyopia of a squinting eye is nearly always acquired from disuse, and it is the realisation of this fact that has been the cause of improved modern treatment. The younger the child when a squint becomes constant the greater the danger of amblyopia ex anopsia, and it is for children between the ages of 3 and 6 that efficient supervision can be most beneficial. The essential cause of squint is a defect in the cerebral function of fusing the two slightly differing images that fall on the retinæ of the two eyes. This power of fusion is a late development in children, and is usually not complete till about the age of 6; often it is absent altogether, but in many cases it is capable of being strengthened by practice—for instance, by Worth's amblyoscope, an instrument which can be adjusted to any angle. As a test for the different grades of binocular vision this instrument is of great service; as a means of education it requires much time and patience on the part either of the surgeon or of someone trained by him.

The theory of squint and the non-operative treatment are the main subjects of the book. Details of the operation for advancement vary in the hands of different surgeons; in describing his own method Mr. Worth lays special stress on the importance of getting a sufficient grip of the sclera with the sutures without going through. He has devised a special cutting needle for this purpose. Uncontrolled tenotomy he condemns, as do nearly all ophthalmic surgeons nowadays, unless for exceptional cases.

and the partial tenotomies practised in America he considers useless. For control he trusts to the lateral expansions of the muscle which should never be divided. He does not mention the plan, now often adopted, of reattaching the end of the divided tendon to the sclera further back than its original insertion.

The Analysis of Drugs and Chemicals.

By Norman Evers, B.Sc., F.I.C., and G. D. Elsdon, B.Sc., F.I.C. London: Charles Griffin and Co., Ltd. 1929. Pp. 372. 25*s*.

The collaboration of a works chemist and a public analyst has resulted in the production of a concise and accurate book of reference. A works chemist is constantly receiving from his firm's customers samples of drugs and chemicals which are reported to have shown deviations from their normal characters; and in the investigation of these many fertile ideas originate. A public analyst, again, usually has a considerable accumulation of disconnected notes arising out of his routine tests which should not be lost to his less-practised colleagues. The reader of this joint work must have some acquaintance with analytical processes, for it is greatly condensed. Of the seven parts into which it is divided, Part V. (Galenicals) is of particular importance, and the appendix is invaluable. Here will be found information on the preparation of reagents, the specific gravity of alcohol solutions (with correction for temperature), the refraction of alcohols, sugar analysis, and the densities of various solutions. The methods described have been well tested, and can be followed with confidence.

Dairy Bacteriology.

By Bernard W. Hammer, Ph.D., Professor of Dairy Bacteriology, Iowa State College; Chief in Dairy Bacteriology, Iowa Agricultural Experimental Station. London: Chapman and Hall, Ltd. 1928. Pp. 473. 25*s*.

Text-books dealing with dairy bacteriology are rare, though in recent years there has been a great extension of our knowledge of the bacteriology of milk and milk products. A comprehensive treatise by Prof. Hammer, whose investigations have contributed so largely to the development of the science of dairy bacteriology, is thus welcome. Its purpose is clearly defined—to supply a practical knowledge of dairy bacteriology to the technical dairyman. The subject is dealt with primarily from the economic standpoint, and the work provides a very complete survey of dairying problems dependent on bacteriology. A clear description of the normal lactic fermentation of milk is given, and of the causes of abnormal fermentations, with classification and characters of the organisms concerned. The chapters dealing with the bacteriology of butter and cheese include a detailed study of the bacterial, chemical, and enzymatic factors concerned in the production of ripeness, flavour, and aroma, and also in deterioration. The bacteriology of other milk products—i.e., condensed and dried milks, fermented milks, and ice-cream—is adequately summarised. Processes of milk preservation are fully described, the advantages and disadvantages of pasteurisation being discussed.

The book should appeal to public health officers as well as to dairymen, for the chapters dealing with contamination of milk and cream, and the precautions necessary for the production of clean dairy products are instructive. Valuable data, of which the tables on page 123 are a type, are given which serve to emphasise the influence of sanitary methods upon the bacterial content of milk. Of special interest to the health officer is the chapter dealing with diseases which may originate from milk and its derivatives or may be conveyed by them. The epidemiologist will appreciate the detailed accounts of recent milk-borne epidemics occurring in the United States. The references to infections by bovine tuberculosis and *Br. abortus* are quite up to date. In this section a summary of the present state of knowledge concerning food poisoning outbreaks due to milk and ice-cream would have been acceptable. An appendix, containing descriptions of the special media for the study of dairy organisms, would also have added to the value of the work, since these are not included in text-books of general bacteriology. The author has wisely embodied results of his own research amongst the valuable data supplied in each section, but he is not dogmatic. Recognition is given to the work of European authorities, such as Orla Jensen, W. G. Savage, and others, although we noticed no reference to the pioneer work of the Institute of Research in Dairying at Reading.

The Art of Anæsthesia.

Fourth edition. By P. J. Flagg, M.D. London and Philadelphia: J. B. Lippincott Company. Pp. 384. 21*s*.

This well-known text-book has been brought up to date, but has not altered much from its original form. As then, the distinguishing feature of the book, which is meant largely for the nurse anæsthetists of America, is the clear explanation of the way in which the phenomena of anæsthesia are produced and of their significance. The language is as plain as the excellent type. A quaint printer's error leads to "the anal sphincter of primiporous cervix" (p. 28). The least satisfactory section of the book is that dealing with chloroform. Here there are but scanty practical instructions, and a still less adequate physiological explanation of the peculiar dangers of the drug; nor is its use in midwifery given the consideration which that important side of chloroform administration certainly demands. The author's division of anæsthesia into two stages of induction, maintenance and recovery, simple and sensible in itself, is so complicated by the numerous subdivisions that we cannot give it preference over the classical four stages which we owe to Snow.

A Book of Crimes.

By A. Salusbury MacNalty. London: Elkin Mathews and Marrot, Ltd. 1929. Pp. 328. 12*s*. 6*d*.

The contents of this volume are ranged under the four headings Murders, Mysteries, Poisonings, and Thefts and Impostures. Of the 12 stories many like those of Madeleine Smith, Mrs. Bravo, Mary Blandy, Lord Ferrers, and Courvoisier are extremely well known, and several of them have appeared in the Notable Trials Series, or have formed the contents of other chronicles of similar character; but in each instance the author has attempted to obtain new information, and in some he advances further speculations towards the solution of remaining problems. Among the stories which will be unfamiliar to many English readers is that of the murder of the Marquise de Ganges, wife of the Sieur de Lande, a young French nobleman who was in attendance at the court of Louis XIV. when the Roi Soleil was at the top of his magnificence. The story of how the Marchioness met her death is elaborated frankly by some imaginative writing, and the fate of the Abbé de Ganges, the youngest brother and leader in the crime, is a sequel rounding off the story too symmetrically for credence, as the author suggests. The last story is that of Jenny Diver, the "dear artful hypocrite" of the "Beggars' Opera," and gives an amusing description of the methods of a beautiful and larcenous young prostitute in the reign of George II.

Dr. MacNalty may be congratulated on his ability to tell complicated stories vividly, and his medical knowledge enables him to lay proper stress on toxicological findings. But in two celebrated poison mysteries the process of unravelling gains nothing from the lapse of time, or the collocation of many theories. We are not helped to any decision as to the guilt of Madeleine Smith or the part played by the wife and the companion in the death of Charles Bravo.

THE LANCET.

LONDON: SATURDAY, OCTOBER 26, 1929.

THE HARVEIAN ORATION.

THE Harveian Oration of the Royal College of Physicians of London was delivered in the College on Friday, Oct. 18th, by Sir WILMOT HERRINGHAM to a full audience. The orator kept that audience deeply interested throughout a narration which, though related so easily, was replete with dated facts and quotations from contemporary sources—that is, contemporary with HARVEY. It will be increasingly difficult for distinguished persons, selected as official mouth-pieces, to find a new way of presenting their pious estimates of certain of our historic heroes, especially HARVEY and HUNTER. One method has been employed with great eloquence by different speakers in relation to HARVEY, and many will remember beautiful discourses, delivered within the walls of the College of Physicians, setting out the way in which HARVEY's fundamental discovery transformed, as soon as its bearings and implications became known, the whole of medicine. But so thoroughly has this line of argument been pursued, that such reflections must, in the future, largely take the shape of showing how modern developments in pathology, as they occur, owe their clinical value to foundation upon the basis supplied by HARVEY. A second approach to the subject has suggested itself to many other orators who have, often with grace and erudition, expounded the text of HARVEY's writings, and borne testimony to the analytical powers which he displayed in what Sir ARTHUR KEITH, from the anatomical point of view, has described as an unerring piece of detective work. A third method of keeping alive in grateful hearts HARVEY's memory would naturally have been to draw a personal picture of the man and make him live before us in biographical shape; this has been done, as far as possible, by several orators, notably Sir GEORGE PAGET, and a fuller carrying out of the design can hardly be attempted for the excellent reason that material for doing it does not exist.

This fact was placed before his audience by Sir WILMOT HERRINGHAM in his first sentences when he described the extraordinary absence of general interest which followed HARVEY's announcement of the true story of the circulation of the blood. Search in contemporary literature and memoirs has brought to light no mention by the leaders of thought in HARVEY's day that the sun of medical truth had risen through the mists of ancient and mediæval speculation; and while the work of HARVEY went unnoticed by those among whom he moved, and who might have brought the news to the public attention, details of his private life are similarly scanty. At considerable intervals Sir D'ARCY POWER and Sir THOMAS BARLOW have resumed for us all that could be ascertained, and, since their researches, Sir WILMOT found that nothing of any consequence had come to light; but he was none the less able, by visualising for his hearers the social milieu in which HARVEY lived, to make "the little man," as he later affectionately called him, a real and intelligible character. As the personal medical attendant of CHARLES I. during that King's long struggle with the Parliamentary Party, HARVEY was in relation with both sides. He accompanied the King to Scotland, and after the detention of CHARLES by the Scottish Army, and during his period of imprisonment, HARVEY received passes through the belligerent lines, enabling him to continue his ministrations. And we get from what HARVEY did not do a suggestive picture of his absorption in what he considered it his duty to do. For practically he never said anything at all about what he either saw or thought. In his writings he mentions the King and Queen but once, and then in the usual terms of respect, while he mentions the Parliamentary Party once also, a little critically in respect of his own professional relations. Thus HARVEY was obviously a doctor and a physiologist, and obviously not either a courtier or a politician. In this connexion Sir WILMOT's researches into HARVEY's family, as represented by his several brothers, became pertinent, and the result of these researches made up much of his narration. All HARVEY's brothers were engaged in trade. They were merchant adventurers, with London as the basis of their operations, while London was from the early days of the revolution the centre of the Parliamentary Party. The probability is, therefore, that as a doctor HARVEY stood by his patient, but that, as far as family tendency or environment went, he was prepared to see eye to eye on many points with Parliament.

And yet the closing passages of the Oration suggested that the mental capacities of the unfortunate King may have appealed to HARVEY's philosophic mind in favourable contrast to the impressions of the intellectual abilities of the protagonists of the revolt. For Sir WILMOT found the leaders of the revolution, though temporarily successful, lamentably wanting in statesmanship, and the results to be not at all commensurate with the drastic nature of their objects or the manner in which they strove to obtain them. In a striking historical survey he drew a picture of the chaos into which the political and social life of the country had fallen by the close of the Protectorate, and, in so doing, he supplied, perhaps, the chief reason why the significance of HARVEY's discovery escaped in an incredible fashion all popular notice. The people were too distraught to be able to respond to anything outside the pressing constitutional and practical needs of the country. Sir WILMOT HERRINGHAM's Oration will long be remembered for its style and the manner of its delivery; it was a happy compound of dignity and simplicity.

THE PURPOSE OF THE BLOOD.

ONE purpose of the blood is well known; it is to carry oxygen and other foods to the tissues, to take away their excreta, and to keep them in such communications with one another as they effect by chemical substances. To serve these ends it is obviously essential that the blood should go round the body; bakers' vans and dust-carts are no use if they stand still. But the blood is something more than a nimble servant of the body; it is a tissue or organ whose chief business it is to be itself, to conserve its own individuality, and to take its place as a sovereign state in the commonwealth of the organism; for these purposes motion is not primarily necessary. It was to this aspect of the blood that Prof. A. E. BOYCOTT devoted his presidential address to the Section of Pathology of the Royal Society of Medicine on Oct. 15th (briefly summarised in our last issue), and he also have a visiting staff of physicians and surgeons who would be paid for their services while retaining the right to private practice. The general practitioner in the neighbourhood of such hospitals would keep in close touch with them and share the sessional work at the clinics. This is the solution of "group medicine," as distinct from that of "State medicine," which was advocated by Mr. T. Swann Harding in the previous number of the *Forum*.

FILTRABLE TUMOURS OF FOWLS.

In casual references nowadays the term "Rous sarcoma" is often used loosely to indicate filtrable fowl tumours in general. This error is an injustice to the fine researches of the staff of the Rockefeller Institute, and, by the implied inference that only one filtrable fowl tumour has been discovered, obscures a problem of cardinal importance. It ought always to be remembered that Peyton Rous and his colleagues described and studied five filtrable tumours, comprising three distinct structural and biological types. No. 1 and No. 43 were simple spindle cell sarcomata; No. 18 and No. 38 sarcomata with a characteristic structure, and No. 7 an osteochondro-sarcoma. These tumours retained their characters during continued transplantation. When loose references to the "Rous sarcoma" are made it is usually tumour No. 1 which is meant, but it is seldom realised that this type is a relatively rare form of avian neoplasm. Since the first publications from the Rockefeller Institute on this subject observers in Germany, Japan, France, and Italy have added other examples of filtrable new growths of the common fowl. In this country two such tumours have been discovered and propagated by Dr. A. M. Begg, the first an endothelioma[1] and the second a fibrosarcoma.[2] During the first three years of its propagation by cell grafts the fibrosarcoma grew slowly—sometimes a year or more elapsed between two transplantations—and formed a hard fibrous mass with the structure typical of a fibroma. In the current number of the *British Journal of Experimental Pathology* Begg describes the subsequent behaviour of the tumour. It has quickened in its rate of growth and become softer and more cellular. Consequently it has now become possible to make filtrates from it, and these have proved to be potent; dried tissue is likewise active. The tumours engendered by both cell-free filtrate and dried tissue reproduce the structure of the parent growth. This change in malignancy calls to mind a relatively common and well-recognised property of the recurrent fibroma of man. The resemblance to a common typical human tumour is thus not confined to gross and microscopic anatomy, but includes also a well-known and serious biological character.

Each addition to the number and histological types of filtrable tumours forces the problem they represent into the foreground of cancer research. The work of Peyton Rous, J. B. Murphy, and their collaborators was buried for years in the obscurity of technical journals, partly because of the overwhelming pre-occupations of the Great War, and partly because filtrable tumours run counter to opinions which had come to be regarded as finally established. Representing a concrete challenge to the biological conceptions of the origin of cancer they demand vigorous investigation. What is the nature of the causative agents present in potent filtrates? Are they viruses of extrinsic origin, or enzymes or other inanimate catalysts, manufactured in, and by, the tumour cell itself? Rous, in his pioneer work on this subject, gave some support to the virus theory, which has been espoused in this country by W. E. Gye. The opposite view that these agents are of intrinsic origin is, for the moment, in the ascendant, but opinion fluctuates as adherents of one or another school are vocal. Prof. A. E. Boycott has argued,[3] by analogy and on theoretical grounds, in favour of the intrinsic non-living catalyst theory. Evidence from experiment must decide this issue, but it is slow to accumulate. So far as the catalyst theory is concerned, almost the only evidence as yet brought forward in its favour is found in the work of Carrel and Brebner and that of Murphy and Leitch on the production of tumours with materials which cannot conceivably contain a virus. Tumour formation can be induced both in fowls and mammals by the application of dead chemical substances—e.g., coal-tar—but by this method the tumours appear only after repeated trauma over a long period of time. In the experiments of Carrel, Murphy, and Leitch the time of tumour formation after one injection was so short as to suggest the action of a specific agent. Carrel and Brebner used normal chick embryo and various chemicals, including arsenious oxide and indol; Leitch, in a solitary experiment, observed a tumour to follow the inoculation of normal fowl pancreas; whilst Murphy achieved the same result by injecting derivatives of normal fowl testis. The experiments of Carrel and Brebner have not been repeated; Leitch has already announced his inability to repeat his single observation, and Murphy's results remain unconfirmed.

It is true that a positive result is of more value than many negatives, and is not to be rejected as accidental until renewed efforts to bring it off again have failed. If it cannot be repeated either the conditions under which it had been obtained have not been completely reproduced or it is due to unnoticed errors which can only be eliminated by repetition of experiments. In the issue of THE LANCET of Oct. 5th (p. 697) Dr. Begg and Dr. Cramer related an experience of their own in which the inoculation of fowls with a simple extract of a mouse carcinoma was followed by the formation of the Rous tumour No. 1 at the site of inoculation. This was an experimental error, and Begg and Cramer were fortunate in being able to trace the sequence of technical operations which led to such a remarkable result. It was found to be due to the accidental use of a mortar, which was contaminated with tumour tissue derived from a No. 1 sarcoma. Such a simple explanation may not suffice to account for any of the unconfirmed observations of Carrel, Brebner, and Murphy—Prof. Leitch has already shown in THE LANCET of Oct. 12th that his observation cannot be explained in this way—but it does indicate the ease with which simple errors can creep unnoticed into biological experiments.

ARE ACCIDENTS A DISEASE?

The study of industrial accidents continues to yield results of practical interest. First, examination of records disclosed that less than 20 per cent. of accidents were associated in any way with those dangerous power-driven machines to which thought naturally turned, while the great bulk originated from circumstances, such as persons falling or articles falling on persons, directly under human control—a control also largely concerned in machinery accidents, as motor-car accidents exemplify. Next, accidents were observed not to be chance occurrences, but to be so distributed that a small group of workers monopolised far more than their due share, according to the laws of chance. Further, clever statistical research established that individuals possess different innate liabilities for sustaining accidents, just as individuals vary in their tendency to succumb to infectious diseases, and that, given knowledge of the accidents experienced in the past by any group of workers, an accurate estimate can be made of the accidents they will experience in the future. Not only so, but those who experienced most accidents were found to suffer most sickness, and—a matter of no small economic import—to be the least efficient workers. Accident causation has been further linked up with the reaction of the worker to his surroundings by finding that there is an optimum temperature, about 67° F., at which the incidence of accidents is least, but above or below which the incidence steadily rises. In fact, if the traumatic origin of the records were unknown, the morbidity and mortality under investigation would certainly be attributed to organic disease. The truth being that organic disease and accidents are end-results of the reaction of the living organism to its environment. Now these investigations of the Industrial Health Research Board have been carried a stage onward by new work[1] wherein tests were sought for by which those inherently predisposed to accidents might be detected. Probably few more unlikely searches have been undertaken; nevertheless no small measure of success has been achieved. It was undertaken by testing 1304 Royal Air Force apprentices, 387 Royal Dockyard apprentices, and 143 naval ratings, concerning whom information was available as to entrance examination results and subsequent accidents experienced. Tests were selected to bring out various characteristics, such as intelligence, stereoscopic vision, power and æstheto-kinetic capacity. The last somewhat cumbrously named tests included (1) responses to visual, auditory, and tactual stimuli; (2) skill at dotting a series of small circles passing by at an increasing speed; and (3) capacity to follow irregular movements of a mechanically controlled pointer. This set of tests enabled a group comprising 25 per cent. of the apprentices to be isolated; this group showed up worst at the tests, and were found to have an accident rate approximately twice that of the remaining 75 per cent. On the other hand, those who did well in these same tests tended to be more proficient in their occupations. Skill at æstheto-kinetic tests was not closely correlated with intelligence indicating that some types of mentality do not go with special sense muscular reactions; and those failing at the tests may include the class naturally fitted for scholastic and sedentary occupations. The capable authors of this report point out how they are breaking new ground with pioneer work, which must be advanced further before its full value can be obtained in practice.

BCG VACCINATION OF PIRQUET-NEGATIVE ADULTS.

In a lecture published in *Tidens Tegn* for Sept. 20th under the alluring title: Will Norway be Free from Tuberculosis in Ten to Twenty Years? Dr. J. Heimbeck, to whose experiments with BCG on Pirquet-negative nurses reference has already been made in these columns, produced some remarkable figures and evolved a new scheme for the campaign against tuberculosis in Norway. His scheme is, in fact, a deliberate challenge to the present order of things in the administrative world of tuberculosis. The three chief headings of his lecture concerned: (1) the Pirquet tests performed by different doctors in various parts of Norway; (2) his own experiments with the subcutaneous administration of BCG to Pirquet-negative nurses, medical students, and others; and (3) a vigorous criticism of the conduct of the present official campaign against tuberculosis in Norway. With regard to the first heading, he showed how recent Pirquet tests had, apparently, upset the teaching that the overwhelming majority of human beings living in civilised communities are infected by the tubercle bacillus before adult life is reached. In Norway less than 50 per cent. of the population become Pirquet-positive during childhood. This observation is of far more than academic importance in view of the possibilities put forward by Dr. Heimbeck with such confident optimism of rendering the Pirquet-negative element of the country immune to tuberculosis by vaccination with BCG. With regard to the second heading, Dr. Heimbeck illustrated the accompanying diagrams with the following observations: In 1924 the communal hospital of Oslo at Ullevaal accepted 109 young women as probationer nurses, of whom 58 were Pirquet-positive, while 51 were Pirquet-positive when they first joined the hospital. As will be seen from the shaded portions of the two columns representing these two lots of probationers, only one of the originally Pirquet-positive probationers developed clinical signs of tuberculosis during her career as a nurse in the hospital, whereas this misfortune befell 17 of the 51 originally Pirquet-negative probationers. As amazingly great a proportion as 28 per cent. of the nurses who were Pirquet-negative on joining the hospital in the years 1924, 1925, and 1926 subsequently developed signs of tuberculosis. In January, 1927, Dr. Heimbeck began to inject BCG hypodermically into those probationers who, on joining the staff of the hospital, were Pirquet-negative, and who were willing to make the venture. As the diagram shows, there were 56 Pirquet-negative probationers joining the hospital this year, and of the 44 who were vaccinated only one subsequently developed clinical signs of tuberculosis, whereas five of the 12 Pirquet-negative probationers, who dispensed with BCG, subsequently fell ill with clinical manifestations of tuberculosis. The very striking difference between the fate of those Pirquet-negative probationers who were vaccinated in 1928 and those who were not vaccinated is indicated in the diagram. Of a total of 136 vaccinated nurses, only three subsequently developed tuberculosis, whereas 14 of the 34 control Pirquet-negative nurses, who were not vaccinated, developed tuberculosis. Dr. Heimbeck and his disciples have begun to give injections of BCG to Pirquet-negative persons outside the hospital, and in one district, Sollien, where this measure was begun two years ago, nearly all the Pirquet-negative inhabitants of this community, to a total of 150, were vaccinated. During this two-year period no new case of tuberculosis has occurred, whereas in the two preceding years there were five such new cases. These carefully controlled hospital experiments have reached a stage when their sponsors consider the time is ripe for advocating this measure beyond the confines of hospitals.

With regard to Dr. Heimbeck's third heading, his criticism of the present order of things is focused on the building of large and costly sanatoriums, where infectious cases are isolated only for a short period, and the provision of special homes for children threatened with tuberculosis, where an attempt is made to defer the date of infection—"a delay, the value of which is doubtful though costly." Dr. Heimbeck would stamp tuberculosis as "the most infectious disease we have," and would act according to this opinion. He recommends the earliest possible isolation of infectious cases, and to this end he advocates tuberculosis homes in which the patients can receive treatment, live and work. As matters stand at present, it is impossible altogether to avoid infection, and BCG vaccination must, therefore, be practised, preference being given in point of time to those who are most exposed to infection—i.e., children in tuberculous surroundings, and such young persons as probationers and medical students who must come in contact with infectious cases. Dr. Heimbeck would like to see the special homes for children threatened with tuberculosis radically converted into vaccination stations, to which these children would be admitted for examination (as to whether they were already infected or not) and for vaccination. Here they would remain, isolated from infectious cases, for the month or two necessary for the establishment of immunity following the vaccination. They would then be sent home, not only well, but also immune to the virulent infections to which they might subsequently be exposed. This system would enable many more children than heretofore to obtain admission to these special homes. Pending the accumulation of further experiences of the results of BCG vaccination, and the education of the community thereto, Dr. Heimbeck advocates a systematic tuberculin survey of the whole of the community, in order that exact information may be available as to

THE SALE OF ARSENIC TO MINORS.

THE general secretary of the Horticultural Trades Association has questioned a statement in a recent annotation (THE LANCET, Oct. 12th, p. 780) on the sale of arsenic to the effect that arsenical weed-killers can be sold to boys of 16. He refers us to Section 2 of the Arsenic Act of 1851, the purport of which was stated in our article, to the effect that "no person shall sell arsenic to any person other than a person of full age." So far as there is any certainty in the interpretation of statutes, it would seem that this prohibition still stands. Section 17 of the Pharmacy Act of 1868 makes it clear that nothing in that Act is to repeal or affect any provision of the Arsenic Act of 1851. Similarly Section 2 of the Poisons and Pharmacy Act of 1908—the section which authorises the sale of arsenical or nicotine weed-killers by duly licensed persons—expressly saves the requirements of the Act of 1851. One would therefore be disposed to agree that the concessions as to the sale of weed-killers by general dealers have in no way negatived the prohibition in the 1851 Act against the sale of arsenic to persons under age, were it not that our learned contemporary, the *Solicitors' Journal*, whose opinion we quoted, appears to take a different view. Our contemporary's article was written by Mr. Marshall Freeman, the recorder of Stamford, a barrister with special knowledge of matters pharmaceutical. It may be that his observations were intended to emphasise the fact that, so far as the rules governing the sale of weed-killers are concerned, there is nothing to warn the distributor that he must not sell to a minor. His opinion, however, certainly seemed to justify the statement that such sales were legal. The doubt thus disclosed is a fresh indication of the unsatisfactory state of the law.

WE regret to announce the death of Dr. William Bevan-Lewis at the age of 82 years. Director for more than 25 years of the West Riding Asylum at Wakefield, and sometime Professor of Mental Diseases at the University of Leeds, he had long been living in retirement at Cardigan, his old home and birthplace.

OUR Medical Diary this week contains an abridged programme of the Conference on Mental Health to be held next week at the Central Hall, Westminster, under the auspices of the National Council for Mental Hygiene and the Tavistock-square Clinic, in association with many other organisations. Applications for tickets and other correspondence should be addressed to the Secretary of the National Council, 78, Chandos House, Palmer-street, London, S.W. 1.

As already announced, an informal "At Home" was held on Wednesday evening last, Oct. 16th, at 7, Adam-street, Adelphi, to inaugurate the removal of THE LANCET to its new home. The house being still empty the rooms were able to accommodate the large number of guests who responded to the Editor's invitation. The removal is now complete and the editing and publishing of the paper takes place from 7, Adam-street, Adelphi.

The number of students entered for the D.P.H. course at the London School of Hygiene and Tropical Medicine already greatly exceeds the earlier expectations of the director and the School Council. The special lectures for the Michaelmas term are all arranged for Mondays at 5 P.M. On Oct. 28th and Nov. 4th two lectures on Atmospheric Pollution will be given by Dr. J. S. Owens and Dr. Leonard Hill, F.R.S., respectively; on Nov. 11th and 18th Dr. Hill will speak on Sunlight and Health, and Clothing and Climate; and on Nov. 25th and Dec. 2nd Mr. J. C. Dawes will deliver three lectures on Disposal of Refuse. All these lectures are open to the public and we hope to publish in due course the programmes for the other terms of the academic year.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XLIX.

URETHRAL AND VAGINAL DISCHARGES.

ALTHOUGH the trained clinician can usually diagnose with some accuracy the cause of a urethral or vaginal discharge, and foretell within limits what the bacteriological findings are likely to be, the assistance of an expert bacteriologist is of definite value. Without laboratory methods gonorrhœa cannot be definitely established nor excluded as the cause of the discharge. Microscopical examination of the urethral and cervical smears is, moreover, helpful as a means of assessing the effects of treatment and of judging improvement in this disease.

Technique of Collecting Samples.

For the examination to be of value to the clinician, it is essential that the material for examination should be taken correctly; much waste of time is incurred by submitting indifferently or carelessly taken specimens for investigation. The gonococcus is seldom found in large numbers in the female genito-urinary tract, and it is an organism which possesses little tenacity of life when removed from its normal habitat. These two facts form the basis of the technique of film and culture taking in modern venereal clinics. In chronic cases positive results are more likely to be obtained immediately after cessation of the menstrual flow. If cultures are desired it is important to avoid delay in transferring the culture tubes to the incubator. Not more than one hour should elapse between the collection of the sample and the introduction of the tube into the incubator.

For the collection of the pus the patient is placed, for preference, in the lithotomy position, and a beam of light from a head lamp or from other suitable source is focused on the vulva.

The *urethral sample* should be taken as long as possible after the patient has last passed urine. The ideal is five hours and upwards after micturition, but this time cannot always be allowed to elapse since frequency of micturition is a feature of some cases in which bacteriological examination is required.

The labia being held apart, the vulva is swabbed from before backwards, in order to remove the possibility of contamination with vulval organisms. Since the favourite resting-place of the gonococcus is in the higher reaches of the urethra that channel should be milked from above downwards through the anterior vaginal wall by means of a gloved finger. The sterilised platinum loop is then introduced into the urethra and subsequently smeared on to a glass slide, or on to the hydrocele-fluid agar, or other suitable medium, if a culture is desired.

Vaginal films, or cultures, are of little value in the adult, except possibly in virginal vaginæ; indeed it is of the utmost importance to avoid contamination of the cervical smear by vaginal organisms, which are apt to lead to confusing results. It is most unlikely that the gonococcus will be found in the vaginal pus of adults, while there exist in this situation other organisms which may be mistaken for it.

Cervical films.—In all cases of purulent vaginal discharge, except in young children, the material to be examined must be taken from the interior of the cervical canal. The cervix is exposed with a bivalve or other speculum which will ensure exclusion of the vagina. The fornices and the vaginal cervix are then mopped dry with gauze swabs on holders, the sterile loop is introduced into the canal of the cervix, and the material thus collected is smeared on to a glass slide or culture medium. If preferred, the ordinary cotton-wool throat swab on a stilette may be used in place of the platinum loop; but if this is used there must be no delay in smearing the slide or culture medium.

Bacteriology.

The *gonococcus.* The finding of an *intracellular*, reniform, Gram-negative diplococcus in this situation is positive evidence that the patient is suffering from gonorrhœa. The finding of *extracellular* characteristic diplococci is, in the overwhelmingly large majority of cases, positive clinical proof that the gonococcus is the infecting organism. It is worthy of note that a positive urethral result is of more value than a positive cervical film. For medico-legal purposes both the meningococcus and the *Micrococcus catarrhalis* should be excluded by their different fermentative reactions. The gonococcus can often be identified by culture, although the smears have failed to yield a positive result.

The *staphylococcus* is commonly found. Occasionally cases of profuse purulent vaginal and urethral discharges are met in which this organism is found alone or in association with diphtheroid bacilli. If repeated examinations fail to reveal the presence of the gonococcus, a diagnosis of staphylococcal urethritis or cervicitis can be made. Such infection is apparently not communicable to the male and rapidly responds to treatment. But the chief importance of the staphylococcus lies in the fact that in its degenerate forms, which have lost the capability of taking Gram's stain, it is sometimes confused with extracellular gonococci. These degenerate, Gram-negative staphylococci are to be distinguished from gonococci by being members of a group, the majority of which are Gram-positive. Their morphology when dividing is, moreover, characteristic.

The *colon bacillus.* Like the staphylococcus, this organism is frequently found in films, particularly in those made from the urethra. It may be the cause of urethritis, the infection being of hæmatogenous origin, and arising as a primary infection in the pelvis of the kidney, or in the bladder as the result of the passage of an infected catheter. In its atypical coccoid forms it may be mistaken for the gonococcus; but in such cases typical bacteria will be seen as well and all gradations in size exist, from the Gram-negative bacillus to the atypical coccoid types. The coccus, moreover, is of larger size than the gonoccocus, and does not possess the typical reniform shape.

The *streptococcus*, in various forms, is found with considerable frequency, especially as a secondary invader, in cases of gonorrhœa, and, of course, in primary streptococcal vaginitis, cervicitis, and urethritis. If the lesion is a *vaginitis* as distinct from a *cervicitis*, the causative organism is almost always the streptococcus. When the urethra is affected the urethritis is associated with cystitis or pyelitis, while in cervicitis streptococci are frequently found in the presence of post-parturitional cervical lacerations. There is little clinical difficulty in differentiating between the infected cervical laceration and the gonococcal erosion of the cervix. The short-chained variety of streptococcus is the commonest. The identification of the hæmolytic streptococcus during pregnancy is of great importance. Its association with puerperal septicæmia is well recognised, and has recently been stressed by H. Burt-White.

The *bacillus of Döderlein* is a large Gram-positive bacillus, often present in the vagina. It does not grow on the ordinary culture media, and it has no pathogenic properties.

Other organisms.—In cases of tuberculosis of the genital tract, excluding primary tuberculous salpingitis, the *Bacillus tuberculosis* may be present in the cervical smears, while, in cases of tuberculosis of the urinary tract, this organism may be found in those from the urethra. In either case it must be distinguished by its acid-fast properties from the smegma bacillus. The *Klebs-Löffler bacillus* is found in the rare cases of aphthous vaginitis. *Diphtheroid bacilli* are relatively common in the vagina, and possess no pathological significance. The *thrush* infection is again rare, but may be surmised in those cases possessing the well-known appearance of oral thrush. Films will show the presence of oidium albicans. The *pneumococcus* is uncommon. It is an occasional cause of hæmatogenous or descending urethritis. In children between the ages of three and ten years the alkaline vaginal reaction and the increased size of the lumen of the vagina make this passage the *via portialis* in cases of primary pneumococcal salpingitis, which, as McCartney and Fraser have shown, is the almost invariable antecedent of pneumococcal peritonitis.

Cytology.

Normally shreds of mucus and squamous epithelial cells are found. The only cellular elements other than these result from inflammation, from ulceration, and from tumour formation.

Inflammation produces excessive desquamation, with increase in the squamous epithelial cell content and the presence of pus cells. In the absence of a *positive gonococcal culture, the presence of a preponderance* of pus cells over epithelial cells, taken in conjunction with suggestive clinical findings, is sufficient to warrant the institution of the treatment for chronic gonorrhœa.

Ulceration.—The findings in this case are pus, blood, and epithelial debris, which may be in clumps. The causative organism will also be found.

Tumour formation.—The malignant growths of the cervix—carcinoma and sarcoma—produce a blood-stained vaginal discharge in which epithelial and connective tissue elements respectively may be found in conjunction with pus and blood cells. By the time carcinomatous or sarcomatous cells make their appearance in the discharge the growth is almost invariably of such dimensions and of such characteristic nature that it can be diagnosed by ordinary clinical methods. The growth at this stage is always secondarily infected. In patients over 50 years of age the possibility of a discharge being due to carcinoma of the body of the uterus must not be overlooked. The findings are similar to those in carcinoma of the cervix, but the secondary infection is usually not so heavy.

Discharges in Children.

In adults the causative lesions, in the majority of cases in which the patient complains of a discharge are urethritis and cervicitis, occasionally vaginitis. In children, on the other hand, the lesion is vulvo-vaginitis. Any of the organisms previously mentioned may be found, particularly the pyogenic bacteria in cases owing their origin to uncleanliness or to the presence of foreign bodies. Parasites and thread-worms are sometimes found, while the disease occasionally occurs as a complication of one of the acute specific fevers. The only place in which the gonococcus is likely to be found is in the vaginal or vulval discharge, whereas in adults the urethra and the cervix are the most likely sites. A determined search must be made and if the bacillus is found a real effort should be instituted to examine all the other members of the family.

The mode of infection in children is sometimes, but not always, by rape. Vulvo-vaginitis spreads rapidly in a family of poor children, and occasionally in a school. Infection in such cases is probably conveyed by the use in common of washing utensils, towels, sponges and lavatories, or by several members of a family sleeping in the same bed.

Discharges during Pregnancy.

It is well known that during pregnancy there is an increase in the physiological secretions; similarly, all pathological discharges become accentuated. The two important organisms for which repeated search should be made are the gonococcus and the hæmolytic streptococcus; the former on account of the danger of ophthalmia neonatorum, the latter because of its relationship to puerperal septicæmia. Primary staphylococcal infections are not uncommon during pregnancy, and give rise to a very profuse discharge which, as has been mentioned, is of relatively little importance.

Criteria of Cure.

A patient can be judged cured of gonorrhœa when, in the absence of all clinical evidence, notably vaginal discharge, the bacteriologist fails to find gonococci in films and cultures from the urethra and cervix on three successive occasions at monthly intervals. It is advisable to conduct a fourth examination two to four months later. Judged on this basis the treatment of gonorrhœa in the female yields very promising results, but the criteria can only be fairly applied to those patients who attend regularly, not to say enthusiastically, for treatment, and who obey to the letter the instructions they receive concerning, for example, marital relations, alcohol, and other excesses. Pessimism is only justified if it takes these factors into account. The reputation of every clinic suffers from the patient who, finding her daily visit irksome, begins to attend less and less frequently, and finally ceases to attend at all. Some patients find it impossible, for fear of detection, to carry out advice. Others are married to husbands who refuse treatment. And so on. There are a hundred and one reasons why a woman cannot do as she is bid. The same reasons explain, and to some extent justify, pessimism.

The complement-fixation test is unreliable, and all authorities are agreed that provocative vaccines are valueless as a means of assessing cure in the female.

From the point of view of cure cases fall into three groups:—

(*a*) Cases in which, clinical manifestations being absent, three successive bacteriological examinations fail to reveal the presence of the gonococcus. Clearly nothing requires to be said of this group.

(*b*) Cases in which repeated bacteriological examinations fail to demonstrate the presence of gonococci, but in which a chronic discharge persists. Secondary invaders, streptococci or staphylococci, are frequently found in considerable numbers, while the discharge contains a high percentage of pus cells. Patients in this group cannot be taken as cured, and the discharge must continue to be regarded as gonococcal, provided the gonococcus was found in the films or cultures at some past examination, however long ago. Repeated search by a skilled clinician working in conjunction with a skilled bacteriologist will, in the large majority of cases, be rewarded with success, and the gonococcus will be found even after a long series of negative examinations. The power of secondary invaders to maintain or to cause a recrudescence of the discharge is extremely dubious. If treatment has effectively eradicated the gonococcus the secondary organisms will have perished. Failure to find the gonococcus usually is due to the fact that the organism lies buried in the deeper crypts and so eludes detection, unless the utmost care and patience are observed in taking the material for examination and in the examination of that material.

(*c*) Cases in which clinical manifestations cease and in which bacteriological examination is negative on three successive occasions, but in which the discharge, with or without other symptoms and signs, reappears at intermittent intervals. Such cases are very similar to those described in the previous paragraph. The gonococcus, if carefully sought, should be found. When not due to reinfection, such a discharge is, as in the male, usually due to some exciting excess, alcohol, chill, intercourse, and the like.

Special Articles.

THE BROWN v. WHITE BREAD CONTROVERSY.

BY GLADYS A. HARTWELL, D.Sc. LOND.;
AND
V. H. MOTTRAM, M.A. CAMB.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON.
(*From the Department of Physiology, King's College of Household and Social Science.*)

So far the brown versus white bread controversy has engendered more heat than light. The upholders of brown bread maintain that brown bread is better than white because it contains more protein of a higher biological value,[1] more vitamin B 1[2]—the antineuritic vitamin—more mineral matter,[3] and more roughage.[4] The protagonists of white bread, while admitting all these points, maintain that an ordinary mixed diet contains so much of these commodities that the deficiencies of white bread are amply compensated[5] and point to the overwhelming instinct of the working classes (which, of course, may be mere prejudice) in favour of white bread as mute and inarticulate evidence of its dietetic value.

The controversy has been complicated by the advent of patent germ breads which have relatively large proportions of the germ of wheat (obtained from the milling of white flour) added to the white flour from which they are made. Such breads contain still more protein of higher biological value, more antineuritic vitamin (B 1)[6] and more toxamins,[7] the poisonous substances discovered in cereal germs by Edward Mellanby. Such toxamins necessitate the addition of more fat-soluble vitamins to counteract their poisonous influence—i.e., demand more milk and butter in the diet, things which the working classes are wont to deny themselves. A still further complication has been introduced by the recent separation of vitamin B[8] into two moieties, B 1 (the antineuritic vitamin) and B 2 (the antipellagric vitamin), and our consequent lack of knowledge of the distribution of these in foodstuffs other than wheat germ and yeast in which their presence has been fully investigated. The adumbration of still further moieties[9] of vitamin B renders the problem still more involved.

At the present it may be taken as certain that brown—i.e., wholemeal—bread contains more protein of good biological value, more vitamin B 1, more mineral matter, more toxamins, and more roughage than white bread, while it contains approximately the same amount of vitamin B 2.

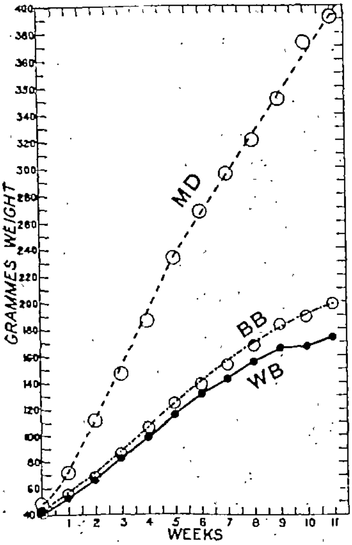
It is very difficult arguing from these data to assay the value of these three types of bread in human nutrition; in fact it may be said at once that nothing but experiments made directly upon human beings will be satisfactory or acceptable to either group of protagonists—long and costly experiments on the lines of those made under the auspices of the Medical Research Council and the Ministry of Health by Dr. Corry Mann[10] upon the value in nutrition of milk. We venture, however, to report an experiment made upon the respective values of brown and white breads incorporated in a mixed diet based upon the analyses of the diet of agricultural labourers in Essex[11] when fed to the laboratory rat.

Experimental Diets.

The diet in question comprised meat, potatoes, vegetables such as beetroot, cabbage, carrot, cucumber (raw), lettuce (raw), green peas, tomato (raw), turnip, sugar, bread, cheese, margarine, lard, milk, bacon, and eggs. The proportions were chosen so that they tallied as nearly as possible with the amounts of these foods used by agricultural labourers. The interpretation of "other vegetables"[11] was left to the discretion of the assistant who was in charge of the animals. The amounts used were in the proportion of meat 10 parts, potatoes 59, vegetables 16, sugar 11, bread 95, cheese 2·5, margarine 4·5, lard 2, milk 20 (by volume), 170 (by volume) of water. Streaky bacon was given twice a week instead of meat and one-quarter of an egg per week beaten in a known portion of the milk and pipetted off. The vegetables were cooked with salt as is usual, the potatoes being cooked separately. The raw vegetables were chopped finely, the tomatoes being skinned first by pouring boiling water over them.

As the food was served ad lib. in the special feeding dishes devised by one of us (G. A. H.) it had to be prepared in the form of a finely divided pulp so that there was no chance of the animals, taking more of one thing than another. The method adopted was as follows: the weighed meat and cheese together with five parts of water to one of meat, and a pinch of salt, were heated in the inner compartment of a double saucepan, with rapidly boiling water in the outer, till the meat turned colour (i.e., it was very lightly cooked). During this short period the mixture was rapidly and constantly stirred. This breaks up the meat into tiny fragments. Into the mixture the fat was stirred. Then the bread was added. The sugar was dissolved in 120 parts of water and poured rapidly over the bread. The mixture was well beaten. The vegetables, which had been previously cooked and thoroughly disintegrated, were added and the whole again beaten together. Last of all the milk, with or without the portion of egg, was added with further beating. When raw vegetables were given they were incorporated with the mixture at the end.

FIG. 1.

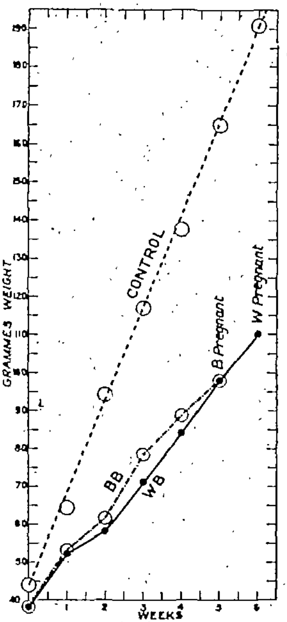


The growth curves of male rats upon the brown bread (B.B.) and white bread (W.B.) diets respectively, with a control curve of the rate of growth of normal male laboratory animals (M.D.) at the same period of the year.

The total amount of mixed food was adjusted to the appetites of the animals, enough being given to leave a small surplus each day.

Twelve animals were used in each experiment, six bucks and six does. One group of 12 were fed on a diet with white bread and the other with brown bread in the mixture. Each buck on the white bread diet was matched against a litter brother of the same weight on brown, and each doe with a litter sister. The average weight was therefore identical, and the litter control complete. The animals were three weeks old at the beginning of the experiment and weighed 40·7 g. (bucks) on the average and 38·3 g. (does) respectively. The experiment ran for 77 days for the bucks and until 10 of the 12 does had produced a litter. The animals were weighed and carefully inspected every day and the growth curves of the males and females are given separately in Figs. 1 and 2. As a control in each case the average growth rates of the stock laboratory animals, male and female respectively, on a mixed middle-class diet are also given.

FIG. 2.



The growth curves of female rats upon the brown bread (B.B.) and white bread (W.B.) diets respectively, with a control curve of the rate of growth of normal female rats at the same period of the year.

Inspection of the curves shows that the males receiving the brown bread diet grew somewhat more rapidly than those on white, though both sets are far behind the normal growth rate on a middle-class mixed diet. This slight advantage in favour of the brown bread diet for males tallies with the results of earlier work.[12 13] Between the females on the brown bread diet and those on the white there is little to choose. When the experiment closed the weights were almost identical in each set, but at intermediate points there had been a slight advantage in favour of the brown bread diet. Moreover, those on the latter diet littered a week earlier than those on the white bread diet.

Condition and Habits of Dieted Rats.

The most that can be claimed for these growth curves is that the substitution of brown for white bread appeared to improve this diet though it brought it by no means near the value of a middle-class diet. This improvement may easily have been due to the coprophagy which developed in those on brown bread (vide infra), for other criteria counterbalanced this increased growth rate.

The routine inspection of the animals showed as regards their physical state the usual signs of defective nutrition, especially the slow growth, the loss of hair (later partly regained), and the lightening in tint of the black patches to grey or fawn previously described.[11] At the end of the second week the hair had begun to fall and this was more noticeable in those on the brown bread diet than those on the white. At the end of the fifth week the lack of colour of hair was seen, and again the brown bread animals suffered more than the white. The hair was normal in quantity in neither set of animals at the end of the experiment. Nine animals on the brown bread diet and two on the white showed incipient xerophthalmia. The teeth were poor, dull, and opaque in appearance, and worse in those on the brown bread diet. Both sets of animals had the prematurely aged appearance of rats on a poor diet.[15]

A striking difference in habits between the two sets was also observed. Those on the brown bread were highly nervous, refused to come at call, and threatened to bite. They needed the more careful handling. Moreover, they showed a desire to consume both the liquid and solid excreta of their fellows, and in time developed an extraordinary cleverness in obtaining such excreta in spite of the usual technique of the use of screens. They waited for the excreta, even removing solid matter from the anal canals of the others before it had time to be voided and fall out of reach. This curious phenomenon appeared at the end of the sixth week in those on brown bread. Three weeks later signs of it, though to a much smaller extent, were seen in those on the white bread diet. Such nervous and gustatory habits have never been seen before in this laboratory in an experience extending over 3300 litters with about half that number of feeding experiments. They lead to the suspicion of a lack of, or more probably an imbalance between, food factors in the brown bread diet.[16]

Summary.

The substitution of brown bread for white in a diet made up to approximate to that of the Essex agricultural labourer, when fed, in carefully controlled experiments, to the laboratory rat, resulted in but small increase in growth and was accompanied by physical and nervous symptoms and by habits pointing towards a lack of, or imbalance between, food factors in the brown bread diet. The experiments give but little support to the propaganda for brown bread in the diet of the working classes.

The cost of these experiments was defrayed by a grant from the Medical Research Council.

THE LONDON MEDICAL EXHIBITION.

THIS exhibition, which for many years has been held at the Central Hall, Westminster, has so grown both in regard to the number of exhibitors and in attendance that the organisers have been compelled to move to larger premises—namely, to the New Hall of the Royal Horticultural Society in Greycoat-street, Westminster. The exhibition closed at the end of last week after a record attendance of medical men both from this country and from overseas, who were enabled thus to measure the progress which has been made in the production of drugs and in the improved excellence of British-made surgical instruments. In the space at our disposal it is possible to mention a part only of some 170 stands, while drugs, foods, and surgical instruments so overlapped—some of the exhibitors catering for several branches of medicine and surgery—that only a general classification can be made.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

BURROUGHS WELLCOME AND CO. (Snow Hill-buildings, London, E.C.), in an attractive exhibit, prominently displayed "Tabloid" Alkaline Compound Effervescent, a therapeutic agent which may be used (1) as an antacid draught, (2) to correct hypo-alkalinity associated with gastric disturbance of various kinds, or (3) to restore the alkaline balance and assist remineralisation in the condition now known as acidosis; "Kepler" Malt Extract, an *important source of vitamin B, and* "Kepler" Cod-liver Oil with Malt Extract presenting vitamins A, B, and D in their natural form and association; and "Tabloid" Brand Hypodermic Bulbocapnine Phosphate, an adjunct to the treatment of certain phases of epidemic encephalitis. A mortality chart recorded the results of insulin treatment on 1310 patients and indicated how case-fatality has decreased as a result of improved technique.—**MAY AND BAKER, LTD.** (Battersea, London, S.W.), had a large display of drugs, including Novarsenobillon ("914") for all stages of syphilis and valuable also in yaws, malaria, rat-bite fever, and anthrax; Metarsenobillon, a water-soluble arsenobenzene derivative specially recommended for use by intramuscular or subcutaneous injection; Mercurochrome-220 Soluble, a powerful antiseptic of great penetrative power and low toxicity; and Arthrytin Ammonium ortho-iodoxy-benzoate in capsules for oral administration, and powder for intravenous and rectal injection in the treatment of chronic arthritis.—**THE BRITISH DRUG HOUSES, LTD.** (Graham-street, London, N.), exhibited a number of their interesting products, new additions being Acetylcholine for the treatment of arterial hypertension and Iodised Tincture of Guaiacol. Attention was particularly drawn to Radiostoleum which is used as a substitute for cod-liver oil and which, it is claimed, has *anti-infective properties*. Radiostol and Radio-Malt were also shown.—**PARKE DAVIS AND CO.** (50-54, Beak-street, London, W., and Hounslow) had a display of drugs which attracted much attention. Their exhibit included a new preparation called Citronin for the treatment of asthma and catarrhal conditions; Estrogen, a hormone-containing substance for the stimulation of the female reproductive organs; Immunogens, a series of antigens including "catarrhalis," "gonococcus," "pertussis," "pneumococcus," "staphylococcus," and "streptococcus"; drugs for the injection treatment of internal hæmorrhoids, and panteric tablets for use in conditions associated with pancreatic deficiency.—**BAYER PRODUCTS, LTD.** (19, St. Dunstan's-hill, London, E.C.). A selection of the well-known Bayer products including Avertin, a basal narcotic administered per rectum which maintains a state of basal anæsthesia through dosage calculated on the body-weight; Compral, a recently introduced analgesic; Phanodorm, an hypnotic; and Theominal, for reducing high blood pressure in arterio-sclerosis, were shown.—**H. R. NAPP, LTD.** (3 and 4, Clement's-inn, Kingsway, London), among other preparations showed Anzypan, a new product intended for the treatment of dyspepsia, embodying both gastric and intestinal enzymes in a form which ensures the release of the gastric enzymes in the stomach and of the intestinal enzymes in the bowel. Put up in the form of "a tablet within a tablet," the interior tablet contains intestinal ferments and is surrounded by a coating which is only soluble when in contact with the alkaline medium of the bowel; Normacol, an intestinal evacuant of vegetable character which gives both bulk and emollience, and thus ensures regular function; Ephetonin, a synthetic ephedrine for the oral treatment of bronchial asthma, hay-fever, and allergic conditions; and Bulbocapnine, an alkaloid of *Corydalis cava* for the treatment of hyperkinetic conditions (paralysis agitans, chorea, &c.). It has also been found of value in the treatment of behaviour disorders of children in post-encephalitic conditions (vide an article in THE LANCET, May 11th, by Dr. T. R. Hill).—THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD. (51, Bowes-road, London, N.), showed a series of preparations including Allonal allyl-isopropyl-barbiturate of dimethyl-amino-antipyrine, a synthetic, non-habit-forming hypnotic and analgesic, which relieves pain and gives sleep, not only in nervous insomnia but in pain insomnia. It contains no morphine, heroin, or opium derivatives; Omnopon, an opium derivative in which the whole of the opium alkaloids are presented in the form of soluble hydrochlorides; and Sedobrol, sedative bouillon in tablet form.

ALLEN AND HANBURYS, LTD. (Bethnal Green, London, E.), had an imposing display of their various drugs and foods including the well-known "Byno" series of tonics: Pitibulin, pituitary (posterior lobe) extract; Crismol, a pure medicinal paraffin; liver products for the treatment of pernicious anæmia; and Cremor Alkalinus for the intensive alkaline treatment of gastric and duodenal ulcer. It is prepared in two forms: (*a*) sod. bicarb. 2 parts; mag. carb., 4 parts; calcium carb., 4 parts; bismuth carb., 1 part; and (*b*) sod. bicarb., 2 parts; mag. carb., 3 parts; calcium carb., 4 parts; bismuth carb., 2 parts; where formula (*a*) proves to be too laxative in effect, the proportion of magnesium carbonate being decreased and that of bismuth carbonate increased.—VITAMINS, LTD. (38, Danemere-street, London, S.W.), exhibited their vitamin food Bemax, which is prepared from the embryo of cereals and possesses a high concentration of B-vitamin as well as a large amount of E-vitamin, and is indicated in constipation, rheumatism, depression, and gastric and duodenal ulcers. It can be taken in milk or in any breakfast food, or eaten with soup or stewed fruit. —PROMONTA CO., LTD. (127, Regent-street, London, W.), showed New-Promonta intended to stimulate the general metabolism and increase the calcium and phosphorus content of the blood. The preparation contains the lipoids of the central nervous system with vitamins A, B, D, and E, lime, iron, hæmoglobin, and soluble lacto-albumins and carbohydrates. It is indicated in neurasthenia, fatigue, insomnia, malnutrition, and conditions of functional insufficiency. FASSETT AND JOHNSON, LTD. (86, Clerkenwell-road, London, E.C.), presented a wide selection of medical and pharmaceutical products including Phyllosan, pharmacological chlorophyll for use in anæmia, debility, convalescence, and all forms of wasting diseases and cardiac affections. Medicinal plasters, dressings, and surgical requisites were also displayed, and attention was particularly drawn to Mead's rubber adhesive plaster which is wound in various widths on a common spool.—PEARSON'S ANTISEPTIC CO., LTD. (61, Mark-lane, London, E.C.), exhibited Hycol, a strong germicidal disinfectant with low toxicity prepared from coal-tar oils, which has a Rideal-Walker coefficient for *B. typhosus* 18–20. It is suitable for dental, medicinal, and surgical uses. Iodine-Medol, a non-toxic and non-irritant antiseptic ointment, was also shown.—SCHERING, LTD. (3, Lloyd's-avenue, London, E.C.), made prominent Veramon, an analgesic whose pain-relieving effects, especially post-operative pain, were emphasised; Atophan, a remedy for gouty and rheumatic conditions; and Medinal, a hypnotic and sedative with absence of cumulative effect; and Vasano, for the prophylaxis and cure of train-, air-, car-, and sea-sickness, also received attention.—HOWARDS AND SONS, LTD. (Ilford, near London), made a special feature of their standard Ether manufactured from duty-free rectified spirit, which is sold at the same price as was formerly charged for ether made from rectified spirit. Agotan Ointment was also prominently displayed, and many fine chemicals such as quinines and quinine derivatives, aspirin, calomel, calcium lactate, and so forth.

(*To be continued.*)

THE OLYMPIA MOTOR SHOW, 1929.

(FROM A CORRESPONDENT.)

THE 1929 Motor Exhibition at Olympia provides striking evidence of the efforts of the manufacturers:

(1) To allow for the average man's dislike of giving his car periodic attention. Maintenance jobs, such as "greasing-round," have in the past been a much shirked duty and are now being largely eliminated or at least simplified.

(2) To make the sensation of motoring more luxurious. This he does by providing smoother running engines and improving the springing.

(3) To take discomfort out of motoring, by better seating accommodation and by efforts to prevent the entry of engine fumes into the saloon body, and so to abolish the saloon headache.

(4) To provide the motorist, as standard fittings, with devices which have until recently been considered accessories to a car, notably radiator shutters, bumpers, and safety glass.

These tendencies are of special interest to the doctor, who has less opportunity than most other professional men to set aside regular occasions to give his car attention; if he neglects the rite of the grease-gun, he is showing the average man's dislike of a thoroughly disgusting job with much more excuse. When the doctor is an owner-driver his car is liable to be neglected, and any action of the motor-car designer to eliminate the penalties of that neglect is therefore acceptable. Certain labour-saving developments are recorded below.

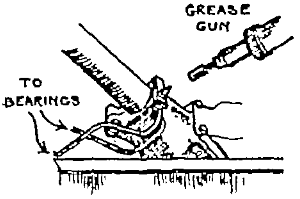
The general refinement of performance in the 1929–30 models is noteworthy. The outstanding characteristic of the Show is the increased use of the six-cylinder engine, and this is a distinct advance towards sweeter running. A year ago the number of makes of car on the market compared as follows: 34·0 per cent. with four-cylinder engines, as against 40·6 per cent. with six-cylinder engines. To-day the difference is: 20·8 per cent. "fours" and 52·5 per cent. "sixes." Six-cylinder cars can now be obtained at prices from £190 and with a horse-power of from 12 upwards. Improvements in suspension are also noticeable and are due to detail alterations to springs and shock absorbers.

Less Noise and Better Ventilation.

Further, to lessen the fatigue of one who has to spend many hours daily in a car, efforts are being made to reduce the noise which frequently emanates from the gear-box. Four-speed gear-boxes are becoming more popular than three-speed boxes, and on some of the cars at Olympia four-speed boxes are provided in which the third speed is claimed to be as quiet as the top gear. These include Graham-Paige and (which were so equipped last year) Humber, Chrysler, Delage, Darracq, Riley, and the new M.G. Advance in gear-box design is also bringing about easier gear changing. The 12 h.p. Austin, for example, is now much easier to change between third and top gears. The admirable "self-changing" gear-box is again shown by the Armstrong Siddeley Company. This is fitted as an extra on the 20 h.p. and 30 h.p. models, but eventually, when factory arrangements permit, this box will be available for all the models. This company is now making only six-cylinder cars, the smallest of the range being the 12 h.p. model, the saloon price of which is £285.

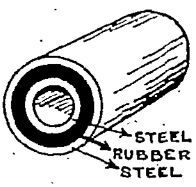
It is extraordinary that in an age when the importance of abundant fresh air and sunshine is receiving unprecedented public recognition, the open motor-car body should be apparently on the verge of extinction. At Olympia this year there are fewer open bodies on view than ever, and most of those displayed are on sports types. Few saloons, however, are adequately ventilated, and on a long journey the choice is frequently between a draught and a headache. The fumes from the engine, which tend to percolate into the body, appear to affect different people in different degrees, but to some a journey of 50 or 100 miles in a saloon car (unless it be in one of the rare well-ventilated types) causes general malaise. If some designer would seriously turn his talent to producing a really leak-proof, non-rattle, inexpensive and rapidly erected hood, possibly open cars would come back into general favour. Meanwhile, on the new 16 h.p. six-cylinder Singer (which takes the place of the previous Senior model, and is the lowest price British six-cylinder car, at £275 for the saloon) glass ventilator panels are provided over the windows. The 2/3 seater (Fig. 6) is £240. An ambitious effort to improve the atmosphere inside a saloon car is to be found on the new 15 h.p. Morris Oxford Six (saloon £285). The engine of this car is equipped with a device enabling it to consume its own fumes.

FIG. 1.



Nipple on the steering column of the Swift, for greasing ten points simultaneously.

FIG. 2.



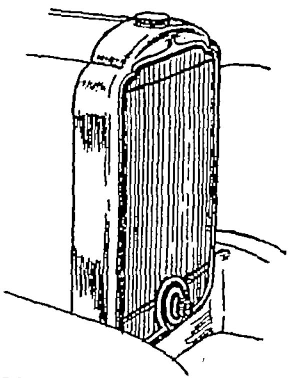
A Silentbloc bearing.

The sunshine roof, if carefully designed, is a useful compromise between the saloon body and the advantages of the open car. Its popularity continues. The Singer design has dropped out, but other makers have improved their designs.

Easy Starting.

The gradual tendency to provide radiator shutters as a standard fitting is welcome. For a doctor who makes journeys involving frequent stops the provision of radiator shutters is essential. The function of these shutters is to keep the temperature of the engine at the most efficient point as nearly as possible, and so to ensure easy starting in winter time. Radiator muffs may be used for this purpose, but they are not nearly so satisfactory as shutters which are either automatic or controlled by hand from inside the car. Automatic shutters, which are to be preferred, are operated by a thermostat which causes them to open in proportion to the increasing heat of the engine and to close the shutters as the engine cools down.

FIG. 3.



The new Buick radiator, with automatic shutters.

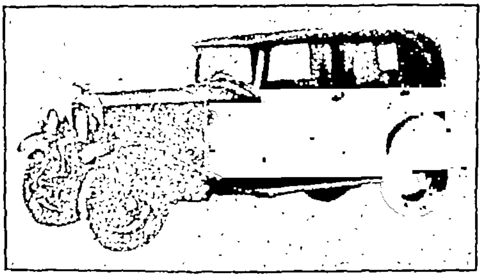
Easy starting is essential to the doctor, and the vogue of coil ignition is therefore important. The magneto system is rapidly losing its popularity, and 60 per cent. of the cars now on the British market employ coil ignition. This is reverting to the system of many years ago, and because motorists in those days had a great amount of trouble with their coil ignition this system is having to overcome a good deal of prejudice. Coil ignition to-day, however, is greatly improved. Its early defects have been cured, and the fear of being stranded owing to failure of the car battery (on which the ignition system depends) need not be entertained with modern batteries, so long as they receive reasonable attention. Coil ignition gives some slight improvement in easy starting and slow running compared with the magneto system.

Easy Greasing.

The 12 h.p. and 16 h.p. Austins employ one of the systems to simplify chassis greasing. The shackles of the road springs are fitted with Silentbloc bushes (Fig. 2), in which hard rubber is sandwiched between the fixed and moving elements of each bearing, so that no lubrication is required between them. The rubber has to take the stress of the constant flexing of the bearing, but according to the makers this torsion has not had any deleterious effect on the rubber during the two or three years that these bearings have been on the market. This year Silentbloc bushes have jumped into popularity, and they are now fitted to A.C., Austin, Alvis, Ascot, Citroen, H.E., Hillman, Humber, Riley, Rover, Standard, Talbot, Trojan, and Triumph cars. They do not, of course, eliminate the job of "greasing round," but they greatly reduce the number of greasing points.

Another and more complete method of tackling the greasing problem is illustrated, among others, on the Singer Super Six. This car has a larger engine than the new six-cylinder model, but the tax is the same (£16). One-shot chassis lubrication is fitted; in this system all the greasing points on the chassis (hitherto lubricated by hand with a grease gun) are connected by piping to a central oil reservoir. By depressing a pedal which operates a plunger in this reservoir, oil is forced to all the points. The price of this saloon is £350.

FIG. 4.



The Vauxhall 20/60 Velox Fabric Saloon.

On the interesting redesigned 40/50 h.p. Rolls-Royce one-shot lubrication is provided to all the chassis bearings except those on the two axles, which are connected by piping to a single accessible grease-gun nipple. This decentralised system has been used in order not to involve the use of flexible tubing between the chassis and the axles.

The redesigned Swift shows how, on a lower price type of car, some of the benefits of one-shot lubrication may be obtained without going to the expense of the complete system. On this much improved car the ten most inaccessible bearings are connected to one central greasing nipple at the foot of the steering column (Fig. 1). The grease gun has to be applied to this nipple, while the more accessible points are greased with the gun in the usual way. The saloon is £260.

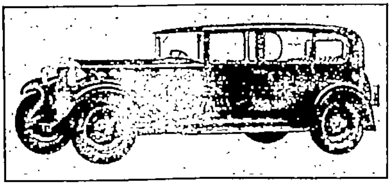
The Buick represents another method. On this car the greasing is by grease gun, but the nipples are grouped together in a small number of accessible places, each nipple being connected to its bearing by piping. The 1930 Buicks have a number of improvements. Automatic radiator shutters are included in the specification (Fig. 3). These cars are big and powerful, the six-cylinder engine being rated at 28·4 h.p. The sportsman's coupé displayed at Olympia is an attractive car in which the doors are not too wide (£535). The saloon is £485.

One-shot lubrication is fitted on the six-cylinder 20/60 h.p. Vauxhalls. These are dignified-looking cars with a fine road performance. The prices range from £495, the fabric saloon shown in Fig. 4 being £565.

On the Wolseley the radiator shutters (hand controlled) are chromium plated. The very smart black 16 h.p. six-cylinder Wolseley is good value at £450. The 21/60 h.p. eight-cylinder saloon is £515. Standard are exhibiting a new car, styled the "Envoy." This version of the 15 h.p. Standard is more roomy and has a slightly larger engine. The saloon is £340, with sliding roof.

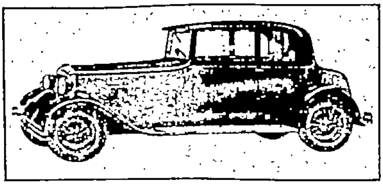
Most of the old-established makers are avoiding extravagant body designs and garish colours. A typical example of the dignified motor-car, such as the doctor requires, is the 14/45 h.p. Talbot. The prices range from £395; an attractive sliding roof coupé is £425. The Sunbeam stand provides another lesson in up-to-date but restrained coachwork. The same applies to the eight-cylinder Hillman (Fig. 5), which also includes Silentblocs and automatic radiator shutters in its specification. This is the least expensive British "eight." As compared with a six-cylinder car, an "eight" gives even smoother running, but the difference is not so marked as between a six- and a four-cylinder engine. The saloon is £445 and there is a drop-head coupé at £510. The four-cylinder Hillman cars have no radiator shutters. Automatic shutters are provided on the new Humber "Snipe" six-cylinder model, and on the new six-cylinder Morris Oxford, the fabric saloon of which is £285. A coupé (not shown at Olympia) is £295. On the adjoining stand at Olympia is the Essex. With an 18·2 h.p. six-cylinder engine this car is fine value for money. Radiator shutters (hand controlled) are fitted. Chassis lubrication (as with the Morris) is by grease gun. Saloon prices range from £250. The convertible coupé (£295) has a big rear compartment which locks.

FIG. 5.



Hillman "Straight Eight" Saloon.

FIG. 6.



The new Singer Six 2/3 Seater.

The Chryslers also have plenty of locker room and are improved in performance and more dignified in appearance. The "66" saloon is £395, and the open two-seater "70" model is £450. On these cars the radiator shutters are imitation, but on the "77" automatic shutters are provided. The "77" (this figure refers to maximum speed) is £625 for the saloon.

The "Babies."

Some doctors favour a "baby" car for short journeys as a second car. The 7 h.p. Austin and the 8 h.p. Morris Minor have established a fine reputation, and now have safety glass and chromium plating. A handsome new coachbuilt saloon Minor with opening head is displayed at £149, and there is an addition to the 8 h.p. M.G. Midget range: a sportsman's coupé with four glass panels set in the sliding roof. This car is well finished at £245, but it is surprising to find the battery box lid uncovered on the floor. The finest show of "baby" car coachwork is on the 7 h.p. Triumph stand, the new saloon landaulet (£197 10s.) being very smart in a black finish, with a folding head, and a trunk at the rear which locks.

Conclusion.

There are some most interesting new cars at Olympia, which are fully described in the current number of the *Autocar*, but the doctor who wants a car for immediate daily and reliable service will be wise to buy a type which has been well tried out. In some cases, doubtless, the designs have been so perfected that they will give little or no trouble, but it frequently happens that, no matter how many thousands of miles a new car has been tested by the makers, some fault is discovered during the first year when thousands of people drive it for thousands of miles.

The equipment of practically every closed car now includes door locks. In some towns, however, the police require car doors to be left unlocked when the car is parked, and in such circumstances the doctor motorist will need a dickey, or some other locking compartment. For this reason the two-seater or coupé type of body has a special appeal to the doctor. The sportsman's coupé type is very popular, but on some of them the doors are too wide for convenient access in a busy street or in the garage.

Chromium plating for the bright parts is now standardised by almost all manufacturers. This also means less trouble in keeping a car in good condition, since chromium plating is non-tarnishable and requires only an occasional rub with a rag.

The doctor who has, or buys, a car not equipped with radiator shutters can, of course, obtain these as an extra fitment. A number of the accessory makers whose exhibits are displayed in the galleries at Olympia are showing shutters and muffs, and in this part of the exhibition there are to be seen a great number of other accessories, some, such as fog lights, of special interest to those motorists whose business or profession takes them out in all weathers.

THE MEDICAL INSURANCE AGENCY.—On Tuesday, Oct. 15th, the annual general meeting of the agency was held at the house of the British Medical Association, and the report covering the twenty-second year of its work was received. This showed that great expansion had occurred. The approved balance-sheet showed that the life assurance now dealt with through the agency approximates very closely to a total of one and three-quarter million pounds, and increases were shown in the sections of sickness and accident, motor-car insurance, and comprehensive household policies. The total premiums for insurance business debited to the agency by the various companies with which its business is transacted amounted to £80,948. The rebates to the doctors insuring through the medium of the agency amounted to £1187.

The following grants were made to medical charities for the year 1929:—

	£	s.	d.
Royal Medical Benevolent Fund	630	0	0
Royal Medical Benevolent Fund Guild ..	630	0	0
Epsom College:			
Dawson Williams Presentation Scholarship Votes	860	0	0
Girls' Education Subcommittee	250	0	0
Royal Home for Incurables, Putney	52	10	0
Sir Charles Hastings Fund	52	10	0
Total	£2,475	0	0

As a result of this distribution the total sum devoted to medical charities by the Medical Insurance Agency since 1910 amounts to nearly £23,000.

Sir Robert Bolam, Lady Barrett, Dr. J. D'Ewart, Lieut.-Colonel R. H. Elliot, and Dr. J. W. Bone were re-elected as directors.

Correspondence.

"Audi alteram partem."

ELECTROCARDIOGRAPH LEADS.

To the Editor of THE LANCET.

SIR,—A false idea about the significance of electrocardiograph leads is widely diffused among students, possibly also among their teachers, and is periodically given further leases of life in successive editions of at least one reputable text-book of medicine.

The heresy is that lead I. chiefly indicates the activity of the auricles, lead II. that of the right auricle and ventricle, and lead III. that of the left auricle and ventricle. That this is untrue can be readily proved, with regard to the auricles, in lead I. by taking any unselected series of tracings, when it will be manifest that it is lead II. which best shows up the P or auricular waves. The inaccuracy of the statement with regard to the other two leads is similarly evident. The truth is that, as Sir Thomas Lewis states (The Mechanism and Graphic Representation of the Heart Beat, third edition, p. 55):—

> "A lead from the right arm to left leg in human electrocardiography is not equivalent to a lead from electrodes placed in experiment on the actual base and apex of the heart. In human work the contacts with the heart are in reality large, they are constituted by the tissue surrounding the heart on all sides. . . . The resultant curves are composite and represent, more in their due proportions, the activity of the heart muscle as a whole."

I trust that this protest may induce editors, and those responsible for the subject in text-books, to search their pages and their consciences with a view to repentance.—I am, Sir, yours faithfully,

London, W., Oct. 22nd, 1929. GEOFFREY BOURNE.

THE DIAGNOSIS OF LARYNGEAL CANCER.

To the Editor of THE LANCET.

SIR,—At a recent meeting of the Section of Laryngology of the Royal Society of Medicine Dr. Jobson Horne read a most instructive and inspiring paper describing cases, culled from the Proceedings, in illustration of difficulties in the diagnosis of cancer of the vocal cords with resulting fallacies in statistics. A common error was the mistaking of tuberculosis for cancer, and if the diagnosis had to be made on laryngoscopical appearances alone it was often excusable. I urged the practice of submitting a fragment removed to microscopical examination before deciding to perform laryngo-fissure or a fortiori laryngectomy—life-saving resorts in cancer and life-endangering in tubercle.

In illustration I exhibited a few lantern slides of such sections from cases in which the previous diagnosis had been incorrect, or in which immediate confirmation of a disputed diagnosis was essential. In one, for instance, the case was supposed to be one of tuberculosis, but the microscope revealed unmistakable epithelioma. This was found on laryngofissure to be so extensive that laryngectomy had to be at once performed, and the patient after five years is now well and hearty. In another, a gentleman of mature years, and of a rather obstinate disposition, refused to accept the diagnosis of cancer until the microscope enabled us to insist on its correctness, when early removal by pharyngotomy resulted in complete and lasting cure. It is not too much to claim that several of these patients would soon have reached the incurable stage, and have lost their lives, if appropriate treatment had not been promptly carried out with the thoroughness that only an exact diagnosis could inspire and justify. The competence of the pathologists, on whose reports the diagnosis in each case was finally established, is beyond question. My friend, Mr. Layton, somehow considered that these slides "afforded a strong argument against biopsies" (see Proceedings of the Section, p. 72). I am sure that my respect for his technical opinion is shared by many of your readers, but I hope they will not allow themselves to be deterred from resorting to this invaluable method for the clinching of the diagnosis, and avoiding the difficulties described by Dr. Jobson Horne.

I am, Sir, yours faithfully,

London, Oct. 21st, 1929. JAMES DUNDAS-GRANT.

SPINOCAIN: THE CONTROLLABLE ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—You published last week an abstract of the papers read by Dr. G. P. Pitkin and Dr. F. A. Kelly to the Section of Anæsthetics at the recent annual meeting of the British Medical Association, describing their new solution "spinocain" and the technique which they employ. These papers seem to have met so far with very little comment. Those, however, who are interested in the subject of spinal anæsthesia cannot but be struck by the surprising amount of stress they lay on the question of the fall of blood pressure, due to the ordinary methods of spinal anæsthesia, which is a point they advance as one of the chief arguments in favour of this new solution. Dr. Pitkin's quotation from a "well-known American author," that "the radial pulse cannot be felt by the fingers, nor can it be detected by the ear when the arm is subjected to the pressure of the cuff of the sphygmomanometer" is hardly the experience of English observers, so that possibly his insistence on the technique which he has elaborated is as much responsible for the improved results obtained in America as his new solution.

During a term as temporary assistant R.M.O. at St. Luke's Hospital, Chelsea, last year, I took blood-pressure readings at five-minute intervals in a series of 25 cases considered suitable for this type of anæsthesia, stovaine being used; only in four of these cases was there any appreciable fall in blood pressure. In two of these latter cases the fall was directly attributable to surgical interference—i.e., clamping the meso-appendix in one case and pulling on an adhesion of the omentum to an old hernial sac in the other.

Stovaine and novocain have their disadvantages and without doubt Dr. Pitkin's method is fairly safe and superior to many others; but his No. 1 spinocain solution contains 1 per cent. of strychnine and his No. 2 solution 3 per cent. of ephedrine. Many authorities maintain that the use of ephedrine temporarily inhibits the action of adrenalin. If a patient should suffer vaso-motor collapse during a spinal anæsthetic, disaster might follow if a preoperative vaso-motor stimulant had been used, which in any way tended to inhibit the use of adrenalin—the only drug that can be used intravenously with the assurance that a rise in blood pressure will almost immediately follow. Moreover, the method at present most widely used in this country that does not require a measured degree of Trendelenburg position and permits of the drug being injected low down in the dural sac has at least the merit of simplicity, and appears to be equally safe.

In any case, far more than in other methods of anæsthesia, success depends much more upon the anæsthetist than upon the particular solution used, and failures are generally due to faults of technique. Correctly administered, within the limits of the indication for its application, spinal anæsthesia is the most satisfactory of anæsthetics, and it is to be hoped that the place given to the discussion on this subject this year will stimulate in this country the greater interest which it deserves.

I am, Sir, yours faithfully,

Norwich, Oct. 17th, 1929. L. SHILLITO.

CURES AND PREVENTION.

To the Editor of THE LANCET.

SIR,—In his letter appearing in your issue of Oct. 12th (p. 793) Dr. W. M. Crofton states that "there is only one efficient intravital *germicide* in the Pharmacopœia, and that is antidiphtheritic serum" (italics mine). It would be illuminating to workers in serology if Dr. Crofton would communicate the evidence on which he bases his theory of the germicidal action of a serum usually regarded as more or less purely antitoxic in therapeutic action. The tissues themselves appear to be an efficient germicide for the diphtheria bacillus, if its toxic products are adequately neutralised.

I am, Sir, yours faithfully,
E. W. AINLEY WALKER.

University College, Oxford, Oct. 16th, 1929.

SUBCUTANEOUS NODULES IN THE SCALP.

To the Editor of THE LANCET.

SIR,—In their paper under the above heading in your issue of Oct. 19th (p. 812) Dr. F. J. Poynton and Dr. Alan Moncrieff refer to the case of a child, which they regard as analogous to their own cases, and which was demonstrated by Dr. Hugh Thursfield, at the Royal Society of Medicine (Section of Disease in Children) on May 22nd, 1925. They say that a subsequent speaker suggested the term "leukæmic lymphadenosis." I was the speaker in question, but I suggested *aleukæmic* (not leukæmic) lymphadenosis. In the printed account the *a* comes at the end of a line, and the hyphen has been omitted, but the context makes the meaning clear. I venture to suggest that both the cases now described by Drs. Poynton and Moncrieff belong to the class of lymphatic leukæmia, of which hypoleukæmic and aleukæmic (including actually leucopenic) lymphadenoses are mere varieties, or sometimes only temporary phases. The blood-counts in the second case are inconsistent with a diagnosis of lymphadenoma (in the sense of lymphogranulomatosis maligna). The frequency of infections in subacute leukæmic cases of all kinds has been long established, and the occasional occurrence of subcutaneous or cutaneous nodules has been recognised. but much less is known of associated bone-changes—see, however, cases recorded by Haenisch and Guerner (*Zeit. f. Klin. Med.*, 1919, lxxxviii., 28), and H. K. Taylor (*Radiology*, 1926, vi., 523), which may have some bearing on the subject.

I am, Sir, yours faithfully,
London, W., Oct. 19th, 1929. F. PARKES WEBER.

*** In describing Dr. Thursfield's case, Dr. Poynton and Dr. Moncrieff refer to "curious nodular swellings in the scalp." We regret that in our last issue the word "curious" was printed as "carious."—ED. L.

MALIGNANT TUMOURS IN THE FOWL.

To the Editor of THE LANCET.

SIR,—The contention upheld by Prof. A. Leitch that it is possible to induce malignancy in fowls by the injection of normal tissues of the fowl or of material obtained from them is of such importance, not only from the pathological but also the biological point of view, that we may be excused for reverting once more to the subject.

In our paper on the Alleged Experimental Production of Tumours in Fowls, published in THE LANCET of Oct. 5th, we emphasised the significance of the similarity of the tumours obtained by Prof. Leitch and Dr. Murphy with the Rous sarcoma No. 1. We pointed out that this similarity is an argument against their contention that they had induced malignancy by the normal tissues which they had injected, and supports our view that their results were due to an accidental contamination with the "agent" of the Rous sarcoma, which can sometimes exhibit an extraordinary virulence. To this Prof. Leitch replies in your issue of Oct. 12th that his tumour was "at first histologically distinguishable from the ordinary Rous sarcoma," and that "one at least of Dr. Murphy's tumours produced by testicular extract was quite distinct."

Our argument was based on the information supplied by Prof. Leitch and Dr. Murphy in their respective papers, published in the official report of the International Conference on Cancer, London, 1928. For the information of your readers we append the relevant *quotation from these two papers. Dr. Leitch writes:*—

> "A year ago in a series of experiments in which normal fowl pancreas was injected into the pectoral muscles, we succeeded in obtaining a tumour of the Rous type, a tumour transmissible by filtrates and desiccates. This tumour had a more solid structure than chicken tumour I. as we know it now. Histologically, it differed in that it had areas of fairly compact spindle cells, and it contained much more mucoid material, rendering filtration difficult. In subsequent generations it has approximated more and more to the classic type until now it is quite indistinguishable from it."

Dr Murphy writes:—

> "We have isolated from such normal tissues as the testicles of normal fowls, not in contact with any tumour-bearing animals, a similar agent with which we have produced the typical tumour, transplantable in over 90 per cent. of fowls."

Neither of the two authors published any figures.

We are, Sir, yours faithfuly, A. M. BEGG.
W. CRAMER.

Oct. 16th 1929.

A POINT IN CERTIFICATION.

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 19th under the heading of Medicine and the Law you deal with the case brought against a colleague and myself for failure to keep a proper register under the Dangerous Drugs Acts. It has been pointed out to me that to the casual observer it would appear that I might have signed a blank piece of paper, and allowed my patient to fill in whatever he or she thought fit. As this same wording has appeared elsewhere, particularly in the lay press, I should like to trespass on your space to state categorically that such was never the case. Every order, &c., signed by me whereof the body was written by someone else has been written under my personal supervision and checked over by me before signature. Although this matter is quite irrelevant to a charge of failing to keep a register, nevertheless since the matter has been raised it is only justice that this fact should be made plain, as also the fact that the magistrate specifically said: "One thing was clear; there was no suggestion against either of these medical men that the regulations were infringed for the purpose of any malpractice in administering the drugs."

I am, Sir, yours faithfully,
REGINALD KARN, *M.C.*, M.R.C.S., L.R.C.P.

Beaumont-street, Portland-place, W.,
Oct. 23rd, 1929.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. J. M. Sloan, late R.A.M.C., retires on retd. pay.

Col. H. E. M. Douglas, V.C., late R.A.M.C., to be Maj.-Gen.

Lt.-Col. W. L. Steele, from R.A.M.C., to be Col.

Maj.-Gen. W. R. Blackwell, late R.A.M.C., to be Dep. Dir.-Gen., Army Med. Servs., War Office.

Maj. W. J. Weston to be Lt.-Col.

ARMY DENTAL CORPS.

G. A. Ballantyne, D.F.C., late Capt., the A.D. Corps, to be Capt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. J. G. Churton and Capt. D. J. F. O'Donoghue, having attained the age limit of liability to recall, cease to belong to the Reserve of Officers.

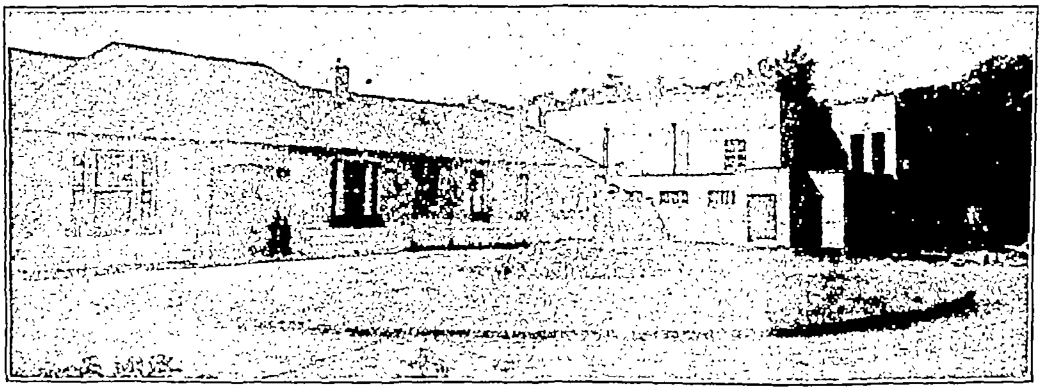
The King has approved of Lt.-Col. E. C. Hodgson, D.S.O., I.M.S., and Lt.-Col. R. B. Ainsworth, D.S.O., O.B.E., R.A.M.C., being appointed Hon. Physicians to the King, and to being promoted to the brevet rank of Colonel.

JORDANBURN PSYCHOLOGICAL INSTITUTE.

(FROM OUR EDINBURGH CORRESPONDENT.)

OPENING OF THE NEW LECTURE THEATRE.

ON Oct. 14th Mr. William Adamson, Secretary of State for Scotland, opened the new lecture theatre of the Jordanburn Nerve Hospital and Psychological Institute at Morningside. This is claimed to be the most complete theatre for medical purposes to be found anywhere. In other respects, too, the occasion was exceptional. It brought together the University, which was represented by the new Principal, Sir Thomas Holland, who here made his first public speech in Edinburgh, the City and the Royal College of Physicians. The three Maces emphasised the official nature of the meeting. Mr. Adamson noted the rapid rise of the nerve hospital and its continuous development as a vital centre for teaching and research. It was, he said, the beginning of a movement to make hospital provision for conserving the mental health of the Scottish people and raising it to a higher level. The old fears which had enslaved the public mind in facing the problems of mental disorder must be robbed of their power; the theatre in which they were met was designed as a deliberate challenge to the exclusiveness of former methods of dealing with disorder of the nervous system. The work of the institution would reach deep down into the life of the nation; the individual sufferers, the difficult and backward children, handicapped for life in many cases, and those who were mentally and morally weak and doomed to become derelict would be helped. There was hardly one branch of the social service in which the coöperation of the medical profession could be safely dispensed with. He understood that some £20,000 was still required to provide the laboratories that were the vital centre from which the whole of the research activities must radiate.



Jordanburn Psychological Institute. On the right is the new Lecture Theatre, on the left the out-patient department of the Nerve Hospital.

Sir Thomas Holland expressed his pleasure that his first public ceremony in Edinburgh should be the dedication of a lecture theatre to a work which would supplement the activities of the University. It was very significant that they had got over the old difficulty of regarding physical disabilities as due to providential intervention. Those who had followed the history of the medical profession would realise what a revolution had occurred since Pasteur discovered that diseases were due to a germ and infection; yet they still went on imagining that mental aberrations were something beyond the reach of research. The Institute would increase the facilities for lectures to students, but it would go much further in undertaking research into the causes of mental disturbances. Here was another opportunity for Edinburgh, largely due to the irresistible enthusiasm of Prof. G. M. Robertson, to lead the medical schools of the world in opening up new ground.

Prof. Lorrain Smith, Dean of the Faculty of Medicine, said that since the days of Laycock the study of mental disorders had been prominent in Edinburgh. He doubted if ever before in this country there had been opened on the same day a hospital which was also an institute for research. Every hospital was moving in that direction, but Jordanburn had done it first. They were introducing there an application of psychology which had never been reached in this country before. This was the day of psychology; so extensive indeed was its application that they could live from a happy childhood to a green old age in the light of pure reason.

Dr. R. A. Fleming, President of the Royal College of Physicians, who agreed that the hospital was unique in Great Britain, suggested to Mr. Adamson that they had in Borstal institutions problems which would be greatly helped by psychological investigation.

Construction of the Theatre.

The lecture theatre has been designed to make it suitable for academic purposes and for semi-popular lectures of an educational character. It is seated for over 250 persons, each of whom will have a perfect view of the platform, which is 34 × 12 feet. Echo has been avoided by covering walls and ceiling with a porous material known as celotex. The backs of the seats have been padded with corduroy, so that if the audience is small there is no echo from wooden benches. The passages are covered with matting. There is thus no hard or smooth surface from which the sound of the voice can recoil, with the exception of the wall at the back of the lecturer, which acts as a sounding board; but its echo follows the voice so quickly that it accentuates the sound of the words without distorting them. The theatre has a cinema, an epidiascope, and a separate complete out-patient department to which admission is obtained from the outer hall. The stage is in a line with the broad corridor of the hospital so that patients in bed can easily be brought along; there is a large anteroom from which admission to the platform is gained, and patients may be held there in reserve.

Staff and Curriculum of the Hospital.

A feature of the hospital is a department for psychology under the directorship of Mr. J. Drever, D.Phil., reader in psychology at the University, and his two assistants, Miss Mary Collins, Ph.D., and Dr. W. R. D. Fairbairn. Pure psychology is now a compulsory subject for the student in the medical curriculum of Edinburgh University, and is taught on alternate days with the subjects of psychiatry and psychopathology during the whole of the spring term.

A few days before the opening an anonymous donor gave a sum of £10,000 as an endowment fund for the working expenses of the lecture theatre and the out-patient department.

LONDON HOSPITAL POST-GRADUATE COURSE.

THIS year for the first time a post-graduate course was held at the London Hospital in connexion with the reunion of the annual dinner. A considerable number of old students attended lectures and demonstrations from Wednesday to Saturday of last week, and the experiment was adjudged a great success, to be repeated, if possible, on a larger scale a year hence. On p. 867 of our present issue will be found the opening paper of the course by Dr. Russell Brain; in a later issue we hope to publish Dr. S. P. Bedson's observations on vaccination, whilst reports of a few of the other addresses appear below.

In the course of some observations on the

Present Position of General Light Therapy

Sir Robert Stanton Woods referred first of all to the two schools of thought which favoured the use of long light rays (luminous) and short rays (wavelength 2900 to 2500) respectively. The theoretical grounds for treatment by light were, he said, by no means well established. One fact, and one fact only, was clear—namely, that exposure of the skin to ultra-violet rays would prevent and cure rickets. But these rays had other probable—indeed, highly probable—effects. In the first place they were bactericidal. This property, however, was of little use in practice, since as bactericides they could not penetrate one bacterial spore to reach another. What was likely to be more important was that it had been pretty definitely shown that exposure of the skin to ultra-violet rays would increase the bactericidal power of the blood. Probably the process here was local and comparable to protein shock—that is to say, it might produce a non-specific immunity reaction. The difference of opinion between exponents of long ray therapy and short ray therapy was conspicuous in the treatment of tubercle, a disease in which light was almost certainly useful, at any rate in the surgical forms. There was reason to suppose that ultra-violet therapy was beneficial also in certain circumstances in frank septicæmia. It would do no good here if the resistance of the body against infection was exhausted, but it might help a patient in whom there still existed the possibility of antibody stimulation. The use of light in other general conditions, and especially in debility, was on even less certain ground; no incontrovertible evidence had been brought forward to show that exposure of the so-called debilitated person to ultra-violet rays had any tonic effect. His own experience had been confined to its employment for definite diseases, and especially inflammatory conditions of joints. He had no doubt that radiation did have some profound good effect in certain forms of subacute and chronic arthritis. In one case, indeed, complete cure had followed such treatment applied after other measures had failed over a period of two years, and though complete success of this kind was exceptional, he had noticed that the general health usually improved under light treatment, and that in the majority the pain and stiffness were greatly alleviated, although he had not yet been able to show that (with the exception mentioned) the pathological joint changes were affected. As for the other effects attributed to ultra-violet rays, there was very little evidence of their utility in medicine. Nor had any means yet been devised for measuring dosage scientifically. Of the two principal methods in use one depended on the measurement of erythema after exposure to the rays, whilst the other was frankly empirical. In treatment some authorities, such as Rollier, began by exposing a small area of skin to light and increased this area gradually; others preferred short exposures of the whole body from the first. The dosage technique depended mainly on the nature of the source employed. It would be seen, said the speaker in conclusion, that the experimental evidence in favour of light treatment was meagre, and that conclusive clinical evidence, which would be much more useful, had yet to be collected.

Mr. Alan Perry gave a lecture demonstration on the

Injection Treatment of Varicose Veins.

Three solutions had, he said, been tried at the London Hospital—namely, 20 per cent. sodium chloride (which had not proved very satisfactory), 30 and 40 per cent. sodium salicylate, and quinine and urethane (1·0 g. quinine plus 2·0 g. urethane in 15 c.cm. sterile water). Special syringes had been used, but any 5 c.cm. syringe would do perfectly well. The ordinary hypodermic needle was too sharply pointed for this work, but could be ground down to a small bevel. Injections might be given with the patient standing up, sitting, or lying down. Preliminary bandaging of the leg was unnecessary. It had been shown that the flow of blood in varicose veins was downwards, and even if the solution injected was not actually carried distally, its flow towards the heart was at any rate very slow. The solution acted by causing swelling and disappearance of the endothelium of the vein. The blood did not simply coagulate, as in thrombophlebitis. A special name had been coined for the inflammatory condition produced—namely, venitis. The consequences of injection were: (1) thickening of the walls of the veins; (2) obliterative sclerosis; (3) obliterative sclerosis and periventitis. When salicylates were used intense cramp might be felt in the leg after injection, lasting perhaps 30 seconds; with quinine and urethane, on the other hand, the treatment was painless at the time. In either case injection was followed in two or three days by thickening along the vein, perhaps with discoloration, and rarely more acute inflammation developed. As a rule, patients noticed improvement after the first injection. Embolism had never occurred in the London Hospital cases, and there was no record in the literature of embolism after injection of salicylates. Sloughing of the skin was an occasional complication but became more infrequent as the operator became more skilled. It was probably due to leakage of solution outside the vein, and although troublesome was not dangerous. The slough took a long time to separate and healing was slow. Fomentations should be used to remove the slough; then a bland ointment could be applied. Patients occasionally fainted, and with quinine they sometimes complained of buzzing in the ears and a taste of quinine in the mouth. In every case a full medical examination should precede treatment, and albuminuria or glycosuria should deter the surgeon from undertaking it. It should be remembered that all pains in the foot and leg were not necessarily due to varicose veins. The treatment was suitable for any tortuous varicose vein up to the saphenous opening, provided that the general medical condition was sound and that there was no generalised œdema of the leg with lymphatic obstruction. Pregnancy was a further contra-indication. Injection should not be attempted for minute superficial varices or when the condition was secondary to deep thrombosis, as in phlegmasia alba dolens. Recent thrombophlebitis also contra-indicated injection treatment.

Modern Treatment of Lead Poisoning.

Dr. Donald Hunter said he knew his audience would agree that so far as industrial plumbism was concerned the treatment was first and foremost preventive. Those who were certifying surgeons under the Factory Acts would appreciate, too, that the Home Office regulations as applied in this country controlled the situation better than any other scheme elsewhere in force. But new sources of poisoning were constantly arising, the most productive at present being the manufacture of electric accumulators. Clinical observation and the evidence of experimental pathology provided abundant evidence that inhalation of dusts and fumes was far more dangerous than ingestion. Extensive chemical analyses after prolonged exposure had shown that lead was stored in the skeleton, probably in the form of tertiary phosphate. Of the total amount in the body 90 per cent. might be immobilised in the bones and while it stayed there it was harmless. A study of the factors causing its elimination and storage had been made the basis of modern therapy. The metabolism of calcium and of lead were very similar so that a low calcium diet favoured the excretion of calcium and of lead, whereas a high calcium diet and calcium therapy favoured their retention in the bones. Therapeutic measures which greatly disturbed the acid-base balance of the blood promoted elimination of lead, probably by mobilising it as secondary phosphate, which was a hundred times more soluble than the tertiary salt. Among agents used for this purpose were phosphoric and hydrochloric acids and their ammonium salts, and sodium bicarbonate; the mode of action of potassium iodide was unknown. The practical conclusions to be drawn from these observations were:—

1. The patient poisoned in industry has shown himself to be susceptible. He must never work in lead again.

2. In the treatment of toxic episodes (colic, palsy, encephalopathy) the patient should have a high calcium diet (milk, eggs, butter, custards, ice-cream, green vegetables, nuts, raisins) plus calcium lactate 3·0 g. daily. Constipation should be combated by enemata and by magnesium sulphate. Colic might be treated with local heat, amyl nitrite, nitroglycerine, and atropine. In bad cases 20·0 c.cm. of a 5 per cent. solution of calcium chloride should be injected *very slowly* into a vein. In palsy (while developing) the general treatment should be as above, together with splints and massage. In encephalopathy, besides treating convulsions and mania symptomatically, calcium therapy was required and intravenous calcium chloride might be necessary.

3. *Elimination* should be attempted only in the absence of toxic episodes. A constant watch must be kept for their occurrence, and if they did occur it was necessary to revert to a high calcium diet and calcium therapy. In all cases a high calcium diet must be resumed after three weeks' treatment. For a low calcium diet the patient might have meat, liver, potato, rice, tomato, banana, apple, butter fat, bread without milk, tea and coffee without milk, sugar, salt, pepper. Dilute phosphoric acid, 20·0 c.cm. (in half a pint of water flavoured with sugar and gin), should be taken through a straw hourly for eight doses a day if tolerated; also ammonium chloride, 1·0 g., in half a pint of water, hourly (eight times daily), if tolerated. The symptoms of acid intolerance were loss of appetite, headache, and nausea; but most patients never developed these. Elimination might be continued for three weeks. It was very much more effective than treatment by potassium iodide. When the patient had nephritis elimination was assisted by sodium bicarbonate, 40·0 g. a day; acids must never be used.

Causes of Sudden Death.

Dr. W. W. WOODS spoke of sudden death in the light of his experience as assistant director of the Institute of Pathology. He subdivided the causes according to the organ affected:—

1. *Heart.*—(*a*) Coronary atheroma and thrombosis. This constitutes the largest of all groups. There is infarction of the myocardium, the anterior descending coronary artery being that most commonly affected. (*b*) Coronary atheroma with stenosis of coronary trunk but no thrombosis. (*c*) Syphilitic aortitis with stenosis of the coronary orifices, the coronary trunks being normal. (*d*) Hæmopericardium either from rupture of the infarcted heart or from rupture of aneurysm of the ascending aorta into the pericardium. (*e*) Aortic incompetence, due to old rheumatic involvement or due to syphilitic aortitis. (*f*) Atheromatous stenosis of the aortic valve.

2. *Cardiovascular.*—(*a*) Cardiovascular hypertrophy either primary or secondary to chronic interstitial nephritis. (*b*) Rupture of aortic aneurysm into œsophagus. (*c*) Spontaneous rupture of the aorta usually presenting a ragged tear about an inch long. (*d*) Perforation of aorta by sharp foreign body impacted in œsophagus.

3. *Lung and Air Passages.*—(*a*) Chronic pulmonary tuberculosis with hæmoptysis and suffocation. (*b*) Foreign body in air passages (pharynx, larynx, trachea, bronchi). (*c*) Pulmonary embolism, large enough to be fatal, occurs only in people just out of bed after an illness. Death occupies several minutes.

4. *Brain.*—(*a*) In cerebral hæmorrhage sudden death only occurs in a very extensive lesion. The patient usually survives several hours. (*b*) Rupture of congenital aneurysm of the circle of Willis. (*c*) Hæmorrhage into a soft glioma. (*d*) Cerebral embolism rarely causes sudden death.

5. *Stomach.*—Perforated gastric ulcer is an occasional cause.

6. *In Infants*, the post-mortem diagnosis presents great difficulty. The condition may be due to: (*a*) Inhalation of vomit—usually white curdy stomach content. (*b*) Overlaying—the exact circumstances leading to the fatality are very important. The lips and nails are blue and petechial hæmorrhages are found in pleura, pericardium, thymus, and testis. (*c*) Convulsions. (*d*) Hæmorrhage into the suprarenals—rare. (*e*) Bilateral thrombosis of renal veins causing hæmorrhagic infarction of the kidneys.

Mr. ROBERT MILNE delivered a lecture on

Pain in the Fore Part of the Foot.

In the causation of such pain he distinguished six main factors: (1) Tight socks and shoes. (2) Tinea or cheiropompholyx affecting the toes. (3) General diseases, such as tuberculosis, syphilis, and gout, affecting the bones and joints of the foot. In these three groups the treatment must obviously be directed to the underlying cause. (4) In a fourth group he placed cases of hallux rigidus and hallux valgus with or without bunion, flat-foot, and hammer-toe. The relative importance of the various factors in the production of the pain must be carefully weighed. In treatment attention to shoes and socks must come first, and might be all that was necessary. If operative measures were deemed advisable they should be as conservative as possible. (5) In another group he placed those cases with a tendency to claw-foot, with or without shortening of the tendo Achillis. Such a tendency would invariably throw too much weight on the fore part of the foot, with consequent pain, chiefly in the region of the head of the first metatarsal. If on examination it was found that the metatarso-phalangeal joint of the great toe could still be straightened, transplantation of the tendon of extensor hallucis longus was justifiable. If the condition was more advanced tenotomy of the tendo Achillis would also be necessary. In many cases nothing further was required than the fitting of a transverse bar of leather to the sole of the boot at a level just posterior to the heads of the metatarsals. (6) Incompetence of the first metatarsal owing to its being either too short or atavistic—i.e., possessing abnormal mobility at its tarsal joint—threw excessive strain on the second metatarsal, and might produce considerable pain in the fore part of the foot. Evidence of this condition might be found in actual osseous hypertrophy of the second metatarsal, callosity of the skin beneath its head, a point of tenderness at its base, and relative thinness of the skin beneath the head of the first metatarsal. In young people actual infraction of the head of the second metatarsal might be demonstrable by X rays. Also apparently spontaneous fractures of the shafts of the second or third metatarsals were not uncommonly found, especially in young adults subjected to excessive or sudden strain on the feet—e.g., route marching. Without radiographic examination such fractures were easily missed. The metatarsal bar was again a great help in treating this group, but in cases where fracture was present rest for the foot for three to four weeks was essential if chronic pain was to be avoided. (7) Mr. Milne mentioned Köhler's disease (a condition allied to Schlatter's and Osgood's diseases) as another cause of pain in fore part of the foot requiring rest. (8) He pointed out that fracture of the fifth metatarsal occurred almost invariably at its base and must be distinguished in X rays from a small accessory bone (bone of Vesalius) which was occasionally present in this region.

Dyspepsias of Childhood.

Dr. ROBERT HUTCHISON began an address on this subject by comparing the dyspepsias of childhood and adult life, referring especially to the relative rarity of organic forms, and the greater importance of the intestine, in childhood. In the child dyspepsia might simulate other things; in the adult other things might simulate dyspepsia. The dyspepsias of childhood could be classified as gastric (acute and chronic), hepatic, and intestinal. In acute *gastritis* the child not infrequently had symptoms of considerable severity—high temperature, repeated vomiting, convulsions, and even coma. These must be distinguished from the symptoms of "acute abdomen" and acute infective diseases, including meningitis. The treatment could be summarised as bed, starvation, and sodium bicarbonate. Chronic gastric dyspepsia of the catarrhal form might follow acute gastritis, or might be due to some source of chronic irritation such as the too free use of roughage in the diet. Chill (from inadequate clothing, &c.) was also an ætiological factor. The child had a diminished appetite, nausea (rarely vomiting), and occasionally attacks of pain in the mornings; it was often constipated and had a coated tongue. Treatment consisted in removing the irritating forms of food from the diet; in seeing that the child had ample time for its meals and masticated efficiently, and in ensuring that the clothing was warm. Rhubarb and soda were the most useful drugs. The functional form of chronic gastric dyspepsia was uncommon in childhood. An atonic variety might be encountered at puberty. *Hepatic dyspepsia* was often seen in children under school age. They were "unsatisfactory" children with capricious appetites, bad tempers, and bad breath; they were pallid and slept badly. Their stools were usually pale and often constipated. They suffered from bouts of vomiting and acidosis, fever, and migraine which might be called "the hepatic episodes." The factors in the production of this form of dyspepsia were an inborn hepatic inadequacy (often hereditary) and over-use of the liver foods such as milk, cream, eggs, chocolate, and oranges. The quantity of these in the diet should be cut down (especially milk). The most useful drugs were rhubarb and mercury, and paraffin was best avoided. *Intestinal dyspepsia*—the so-called mucous disease—was found usually in children of school age (6–12 years). These also were "unsatisfactory" children; they were languid, and dark under the eyes; they had disturbed nights with terrors or sleep-walking; they had attacks of pallor or fainting, and of night sweating. They had poor appetites with occasional voracious hunger, they passed jelly in the stools, and they were not often constipated. They also suffered from "episodes," which include bouts of lienteric diarrhœa, umbilical colic (in which the pain might be severe, but was always short-lived, and might recur several times a day). They were subject to fainting and worms. These cases must be distinguished from chronic appendicitis and abdominal tuberculosis. The important factor in their production was the over-use of carbohydrate in the diet, which induced an excessive secretion of mucus in both stomach and intestine. The supply of carbohydrate should therefore be cut down. Useful drugs were alkalis, rhubarb, nux vomica, bitters, and such laxatives as aloes and senna. Paraffin again was best avoided; iron was unnecessary and cod-liver oil and malt should not be employed at the outset of treatment. For diarrhœa and colic a few drops of tincture of opium (with or without belladonna) could be given before meals and a laxative at night. In the treatment of worms in these cases it was essential to recognise the underlying dietetic error. In all these forms of dyspepsia general regulation of life and change of surroundings (people and place) were of great importance.

Mr. A. J. WALTON gave a short lecture on the

Place of Surgery in Lesions of the Upper Abdomen.

Dealing first with lesions of the stomach and duodenum, he distinguished four pathological groups: (1) The first was congestion of the mucosa, sometimes with small superficial erosions. This condition was seen, for example, in connexion with purpura, with heart failure and back pressure, and with burns or general sepsis, in all of which conditions the history might be one of acute onset with severe gastric symptoms. These cases obviously did not require surgical treatment. (2) The small multiple erosions of the stomach found in the dyspepsias of young women should also be treated medically; except in cases with severe or repeated hæmatemesis, when a rapid gastro-jejunostomy might be needed to save life. (3) In a separate group he placed gastric and duodenal ulcers of moderate size, giving a short but typically periodic history of dyspepsia, usually with a raised gastric acidity and some radiographic evidence of abnormality. Medical treatment was being widely advocated in such cases, but Mr. Walton said that he himself was not yet convinced of its success and that he still advocated surgical measures. (4) Large chronic penetrating ulcers giving a long history should, in his opinion, always be treated surgically, especially in view of the gravity of the complications—i.e., severe and occasionally fatal hæmorrhage, perforation, stenosis, and carcinoma—all of which might occur despite careful medical treatment. The danger that gastro-jejunal ulcer and lesser curve ulcer might follow gastro-jejunostomy for duodenal ulcer was often mentioned in argument against surgical treatment, but both these sequelæ were usually associated with a failure to reduce gastric acidity and this could almost certainly be avoided by correct and careful technique. It was extremely rare for carcinoma to develop in cases treated by gastro-jejunostomy. Quoting from his own figures, Mr. Walton said that from 80–92 per cent. of cases of gastric and duodenal ulcer treated surgically were free from symptoms five years after operation, and maintained that at present no figures of the results of medical treatment could compare with these. Going on to speak of disease of the gall-bladder, he advocated surgical treatment in certain cases of gall-bladder dyspepsia even when the pressure of stones could not be proved. He showed several gall-bladders removed from such cases in which extensive deposits of lipoid and, in some, small concretions, were present in the walls; which conditions, he contended, were very unlikely to be touched by medical treatment. In undoubted cases of cholelithiasis surgical treatment must be advised, and cases of acute cholecystitis should be operated upon as soon as diagnosed.

FEDERATION OF THE HEALTH RESORTS OF FRANCE.—A medical tour has been arranged by the Société Médicale du Littoral Méditerranéen to take place from Dec. 26th to Jan. 8th. It will include a visit to Marseilles, Toulon, Hyères, St. Raphael, Cannes, Le Cannet, Grasse, Juan-les-Pins, Nice, Menton, Monaco, Monte Carlo, Beaulieu, San Remo, Bordighera. Full particulars can be obtained from Madame Juppé-Blaise, Federation of the Health Resorts of France, 1, Gordon-square, W.C. 1.

ALMONERS UNDER THE LOCAL GOVERNMENT ACT.—A meeting of the Hospital Almoners' Institute has been held at the Leeds General Infirmary at which the position of almoners under the Local Government Act, 1920, was discussed. It was pointed out that the local authorities who take over poor-law hospitals will greatly need the help of trained almoners for follow-up work, since beds can only be emptied reasonably quickly by ensuring that the patients upon leaving go home to suitable conditions.

They had been well in the running for nearly all events, being beaten by 3 points in the Rugger final, and finishing in the semi-finals of the cricket and hockey. They had won the rifle cup, and (incidentally) the tug-of-war for the third year in succession. For old students of the hospital a post-graduate course was now in successful progress, and he welcomed this new departure because it would help to prevent London men from feeling themselves dissociated from their hospital. It was wrong that those who had spent five years there should come back as strangers, and he wished that they would more often return and introduce themselves to members of the staff on rounds in the wards or in the out-patient department, when they would be sure of a warm welcome. After referring to the work of Lord Dawson, Sir Hugh Rigby, and Sir Robert Stanton Woods during the King's illness, Mr. Lett went on to speak of senior members of the company present. These included Rampley, long in charge of the single operating theatre of the hospital, now in his eighty-sixth year, and the guide and friend of many generations of students; Sir Alfred Rice-Oxley; and Sir James Clark, son of Sir Andrew Clark. Their names recalled to Mr. Lett the days when general surgeons operated on everything; when there were no rubber gloves and sterilisation of the hands was carried so far that one surgeon used to snip off bits of his assistants' fingers and make cultures to see that they were sterile; when information about cases had to be sent up to Harley-street in a cab; when "compulsory anæsthetic" was an apt description of a process which often needed the coöperation of a member of the Rugger XV.; when the routine was that patients with fractures should be treated preventively for delirium tremens; and when the staff were met by their house surgeons in pomp and circumstance and morning coats.

Mr. George Neligan proposed the health of the chairman. "You will find him," he said, "in every walk of the life of the hospital, doing his work quietly; and if he gets what he wants then the thing is a success." Mr. Neligan believed that nowhere would be found a happier staff than that of the hospital at the present day, and so long as it contained men like Mr. Lett he failed to see how any Act of Parliament could do it down. After the chairman's health had been drunk to appropriate music, Mr. E. C. Lindsay said a few words as joint secretary of the dinner, and Dr. Russell Andrews told only one story—his meagre answer to a demand which has to be satisfied before any London Hospital dinner can be called complete.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Oct. 28th.—8 P.M., ODONTOLOGY. Presidential Address. Mr. J. McK. Ackland: Oral Sepsis in its Relation to General Disease. Casual Communication. Mr. F. N. Doubleday: Two Cases of Hypertrophy of the Jaw.
FRIDAY, Nov. 1st.—10.30 A.M., OTOLOGY (Cases at 9.30 A.M.). Presidential Address. Mr. W. M. Mollison: Triumphs and Failures of the Mastoid Operation. Papers have been promised by Mr. G. J. Jenkins, Mr. L. Graham Brown, and Mr. J. P. Stewart. Cases will be shown by Mr. Mills, Mr. L. Graham Brown, and others. 5 P.M., LARYNGOLOGY (Cases at 4 P.M.). Cases will be shown by Mr. W. S. T. Neville, Dr. Dan McKenzie, Mr. V. E. Negus, Mr. H. A. Kisch, Mr. T. B. Layton, and others. 8.30 P.M., ANÆSTHETICS. Discussion on Avertin Anæsthesia. Openers: Dr. J. Blomfield and Sir Francis Shipway.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Oct. 28th.—8.30 P.M., Discussion on Radium Therapy, to be introduced by Mr. A. E. Hayward Pinch and Prof. Sydney Russ.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
MONDAY, Oct. 28th.—5 P.M., Mr. C. P. Wakeley: Specimens of Calculi.
FRIDAY, Nov. 1st.—Sir Arthur Keith: Spinal Deformities in the Sacro-iliac Region.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 28th, to SATURDAY, Nov. 2nd.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Lecture by Dr. Maurice Davidson: Coughs. No fee. Tues., 8.30 P.M., Lecture by Dr. A. F. Hurst: Recent Work on Disorders of the Stomach. Fri., 8.30 P.M., Lecture by Dr. J. W. McNee: Recent Views on Diseases of the Liver and Biliary Tract. Specially suitable for M.R.C.P. candidates.—ST. BARTHOLOMEW'S HOSPITAL, City-road, E.C. Thurs., 1.30 P.M., Demonstration of Cases in the Wards by Sir Thomas Horder. No fee.—SAMARITAN HOSPITAL FOR WOMEN, Marylebone-road, N.W. Thurs., 10 to 12.30 P.M., Gynæcological demonstration by Mr. McKim McCullagh. No fee.—METROPOLITAN HOSPITAL, Kingsland-road, E. Special post-graduate course in Medicine, Surgery, and Special Branches. Daily, 10.30 A.M. to 5.30 P.M., demonstrations, operations and lectures.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Fri., 5 P.M., First of four weekly demonstrations in Antenatal Treatment by Prof. Dame Louise McIlroy.—CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C. Third week of course of Clinical, Ear, Nose and Throat work. All day.—Further particulars from the Fellowship of Medicine.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.
FRIDAY, Nov. 1st.—4 P.M., Dr. W. J. O'Donovan: Skin Diseases Common to Animals and Man.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Oct. 30th.—4.30 P.M., Mr. Stanford Cade: The Limitations of Radium Therapy on Genito-urinary Diseases.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 29th.—5 P.M., Dr. K. Sibley: Principles of Treatment. Local.
THURSDAY.—5 P.M., Dr. H. G. Burford: Pathology Demonstration.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 28th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.
FRIDAY, Nov. 1st.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.
MONDAY, Oct. 28th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.
TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.
WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 4.30 P.M., Dr. Carter Braine: X Ray Therapy.
THURSDAY.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.
FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.
SATURDAY.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.
Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits, Anæsthetic Courses.

NATIONAL HOSPITAL, Queen-square.
MONDAY, Oct. 28th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Syphilis of Nervous System.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Bernard Hart: Disorders of Memory.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Nervous Symptoms in Sinusitis.
FRIDAY, Nov. 1st.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Some Infectious Diseases of Nervous System.

INSTITUTE OF HYGIENE, 28, Portland-place, W.
WEDNESDAY, Oct. 30th.—3.30 P.M., Dr. T. J. Hoskin: Heart Affections: Cause and Prevention.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Oct. 30th.—4 P.M., Dr. A. F. Hurst: The Asthma Problem.
FRIDAY, Nov. 1st.—5 P.M., Prof. R. A. Peters: Coördinative Biochemistry of the Cell and Tissues. (Third Harben Lecture).

ROYAL ANTHROPOLOGICAL INSTITUTE.
FRIDAY, Nov. 1st.—5.30 P.M. (in the Polytechnic Hall, Great Titchfield-street, W.), Dr. G. Elliot Smith: The Evolution of Man (Public Lecture).

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.
MONDAY, Oct. 28th.—5 P.M., Dr. J. S. Owens: Atmospheric Pollution.

CHADWICK PUBLIC LECTURES.
TUESDAY, Oct. 29th.—5.15 P.M. (at the House of the British Medical Association, Tavistock-square, W.C.), Prof. J. Boeke (Utrecht): The Tissues of Youth and Age.
FRIDAY, Nov. 1st.—5.15 P.M., The Nervous System in Relation to Health.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, Albert Embankment, S.E.
TUESDAY, Oct. 29th.—5 P.M., Dr. A. St. G. Huggett: Physiology of the Fœtus. (Fourth lecture.)

CONFERENCE ON MENTAL HEALTH, Central Hall, Westminster, S.W.

Wednesday, Oct. 30th.—8.30 P.M., Inaugural Meeting. Sir Maurice Craig, Dr. Letitia Fairfield, Sir Frederick Willis, Dr. F. E. Fremantle, M.P., and others. (Chairman: Lord Brentford.)

Thursday.—4.30 P.M., Dr. H. Crichton-Miller, and others: Sex Education. 6 P.M., Working of the Juvenile Courts. 8 P.M., Dr. Millais Culpin and Prof. Winifred Cullis: Personal Equation in Industry.

Friday, Nov. 1st.—2.15 P.M., Dr. H. P. Newsholme and others: Place of Mental Hygiene in Social and Public Health Work. (Chairman Sir George Newman.) 4.30 P.M., The Child and the Parent. 8 P.M., Dr. J. A. Hadfield and others: Delinquency, A Problem in Mental Hygiene.

Saturday, 11 A.M., Dr. E. A. Hamilton-Pearson and others: The Problem Child at Home and in School. (Chairman: Dr. R. H. Crowley.)

KING'S COLLEGE FOR HOUSEHOLD AND SOCIAL SCIENCE, Campden Hill-road, W.

Friday, Nov. 1st.—5 P.M., Prof. V. H. Mottram: Human Nutrition. (Third of six lectures.)

KING'S COLLEGE, Strand, W.C.

Tuesday, Oct. 29th.—5 P.M., Mr. J. W. Pickering, D.Sc.: Blood Plasma and Platelets. (Fourth lecture.)

Thursday.—5 P.M., Mr. J. A. Hewitt, D.Sc.: Metabolism of the Carbohydrates and Fats. (Third of four lectures.

UNIVERSITY COLLEGE, Gower-street, W.C.

Monday, Oct. 28th.—5 P.M., Dr. R. J. Brocklehurst: Secretion of the Digestive Juices. (Third of four public lectures.)

Friday, Nov. 1st.—5.30 P.M., Mr. C. S. Elton: The Future of Animal Ecology. (Second of three lectures.)

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Oct. 29th.—4.15 P.M., Mr. G. Jefferson: Concerning a Series of Pituitary Tumours.

Friday, Nov. 1st.—4.15 P.M., Dr. W. Sage Sutherland: Uses of Antiscarlet Fever Antitoxin.

ANCOATS HOSPITAL, Mill-street, Manchester.

Thursday, Oct. 31st.—4.15 P.M., Dr. A. Renshaw: Cystological Changes in the Blood and their Significance

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.

Friday, Nov. 1st.—3.30 P.M., Dr. Grout: Radiological Examination of the Gastro-intestinal Tract.

Appointments.

Bates, H. T., M.B., B.Ch., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Addingham District of the County of York, West Riding.

Clark, R. J., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health, Cheshire.

Potts, T. N. V., M.D., B.S. Durh., D.P.H., Medical Officer of Health to the West Riding County Council.

Sharman, Albert, M.B., Ch.B. Glasg., Extra-Surgeon, Out-patient Department, Royal Samaritan Hospital for Women, Glasgow, to a McCunn Research Scholarship in Gynæcological Surgery.

Vacancies.

For further information refer to the advertisement columns.

Adelaide University.—Elder Professor of Anatomy and Histology. £1100.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.

Bath, Royal United Hospital.—Asst. H.S. At rate of £100.

Bedford County Hospital.—Asst. H.S. At rate of £130.

Bethnal Green Hospital, E.—Asst. M.O. £350.

Birmingham City.—M.O. for Maternity and Child Welfare. £600.

Birmingham General Hospital.—H.P. £70.

Bolton, Townleys Hospital, Farnworth.—Second Asst. M.O. £225.

Bradford Royal Eye and Ear Hospital.—Jun. H.S. £150.

Bradford Royal Infirmary.—H.P. £150.

Brighton, Sussex Maternity and Women's Hospital.—Res. H.S. £130.

Cambridge, Physiology School.—George Henry Lewes Studentship in Physiology. £250.

Cancer Hospital, Fulham-road, S.W.—Part-time Research Radiological Asst. 1 gn. each attendance. Also H.S. At rate of £100.

Cardiff, Glan Ely Tuberculosis Hospital, Fairwater.—Asst. Res. M.O. £250.

Carlisle, Cumberland Infirmary.—H.P. At rate of £155.

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Asst. S.

Charing Cross Hospital, W.C.—Hon. Clin. Asst. for X Ray Dept. Also Res. M.O. £350.

Chester Royal Infirmary.—H.S. £120.

Coventry and Warwickshire Hospital.—Res. H.P. £160.

Derby, Derbyshire County Sanatorium, near Chesterfield.—Res. Asst. M.O. £350.

Dewsbury County Borough.—M.O.H. and School M.O. £900.

Dover Borough.—Asst. M.O.H. £700.

East Ham County Borough.—Deputy M.O.H., &c. £700.

Evelina Hospital for Children, Southwark, S.E.—H.P. At rate of £120.

Exeter, Royal Devon and Exeter Hospital.—H.S. to Special Depts. At rate of £130.

Gloucester, Gloucestershire Royal Infirmary.—Second H.S. At rate of £100.

Gravesend and North Kent Hospital.—Jun. H.S. At rate of £80.

Great Yarmouth General Hospital.—Jun. H.S. £125.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. M.O. At rate of £250.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W. Res. H.P. At rate of £100.

Hull Royal Infirmary.—Hon. Ophth. S.

Italian Hospital, Queen-square, W.C.—Res. M.O. At rate o £150.

Jersey General Hospital, &c.—Res. M.O. £200.

Kingston-upon-Hull City and County.—Asst. M.O.H. £600.

Leicester, Leicestershire County Council.—Asst. County M.O.H. £650.

Liverpool, Alder Hey Children's Hospital, West Derby.—Res. Asst. M.O. £200.

Liverpool County Borough.—Jun. Asst. Sch. M.O. £600.

London Hospital, E.—Dental Anæsthetist.

London Jewish Hospital, Stepney Green, E.—Hon. Asst. Radiologist.

Manor House Hospital, Golders Green, N.W.—H.S. At rate of £200.

Middlesex Hospital and Medical School, W.—Medical and Surgical Registrar. £300.

Miller General Hospital, Greenwich-road, S.E.—Orth. H.S. At rate of £150. Hon. Surg. Also Hon. Physician to Skin Dept.

Northwood, Mount Vernon Hospital.—Asst. Pathologist. £500.

Nottingham General Hospital.—Second Cas. O. At rate of £150.

Oldham, Poor-law Institution, Rochdale-road.—Res. Asst. M.O. £200.

Plymouth City.—Asst. M.O.H. for Maternity and Child Welfare Dept. £600.

Portsmouth Royal Hospital.—Sen. H.S. At rate of £175. Also H.P. and two H.S.'s. Each at rate of £130.

Prince of Wales's General Hospital, Tottenham, N.—Hon. Med. Reg.

Queen's Hospital for Children, Hackney-road, E.—Clin. Asst. for Orthopædic Dept. 5s. each attendance. Cas. O. £100. Also Surgeon to Ear, Nose and Throat Dept.

Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. At rate of £250.

Royal London Ophthalmic Hospital, City-road, E.C.—Surgeon to Ear, Nose and Throat Dept. Also Out-patient O. £100.

Royal Naval Dental Service.—Dental Officers.

Royal Society, Burlington House, W.—Foulerton Research Student. £700.

St. Mark's Hospital for Cancer, &c., City-road, E.C.—Clin. Assts.

Sheffield City Hospitals, Infectious Diseases.—Res. M.O. £350.

Sheffield University, Faculty of Medicine.—Lecturer in Pathology. Also Demonstrator in Pathology. Each £500.

Southern Rhodesia Government.—Director of Public Health and Medical Services. £1750.

Stroud General Hospital.—H.S. At rate of £125.

Swanley, Kent, Alexandra Hospital for Children with Hip Disease.—Res. Asst. M.O. At rate of £300.

Walsall General Hospital.—Sen. H.S. Also H.S. At rate of £200 and £150 respectively.

West End Hospital for Nervous Diseases, Welbeck-street, W.—Hon. Asst. Physician.

Weymouth and District General Hospital.—H.S. £180.

Windsor, King Edward VII Hospital.—Hon. Asst. S.

Worcester General Infirmary.—Sen. Res. M.O. £180. Also Jun. Res. M.O. £120.

The Chief Inspector of Factories announces vacant appointments for Certifying Factory Surgeons at Ammanford (Carmarthen) and Milborne Port (Somerset).

Births, Marriages, and Deaths.

BIRTHS.

Addison.—On Oct. 18th, at Wilbraham-place, S.W., the wife of Dr. G. M. Addison, of a daughter.

Farman.—On Oct. 7th, at Haverstock-Hill, N.W. the wife of Dr. Noel B. Farman, of a son.

Mathews.—On Oct. 14th at Kirkby Lonsdale, the wife of R. G. Mathews, M.B., B.Ch., of a son.

Reichwald.—On Oct. 20th, at Timber Hill, Ashtead, Surrey, the wife of Dr. M. B. Reichwald, of a son.

MARRIAGES.

Barnes—Newman.—On Oct. 16th, at St. Philip's Church, Kensington, Warren Alston Barnes, M.B., B.Ch., to Helen Newman, M.B., B.S., elder daughter of the Rev. and Mrs. Herbert Newman, of Stone, near Ashford.

DEATHS.

Bevan-Lewis.—On Oct. 14th, William Bevan-Lewis M.Sc., L.R.C.P., M.R.C.S. Eng., of Priory-street, Cardigan, aged 82 years.

Lee.—On Oct. 15th, at "Sainssoins," Little Shelford, Cambridge, Crichton Stirling Lee, M.R.C.S., L.R.C.P., aged 50.

Rouse.—On Oct. 14th, suddenly, at Monte Carlo, Rolla Edward Rouse, M.D., in his 70th year.

N.B.—A fee of 7s. 6d is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE HEALTH AND CONDITIONS OF WORK OF MEDICAL STUDENTS.*

BY E. GRAHAM LITTLE, M.D., F.R.C.P., M.P.,
PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT AT ST. MARY'S HOSPITAL.

I. HEALTH.

MY choice of subject was dictated by the consideration that I gave the corresponding inaugural lecture last year upon the Health of the Doctor, and it was suggested to me that an inquiry into the health of the embryo doctor might be useful. I was filled with consternation, however, when I began to come to grips with the subject, at the nearly complete absence of any data, which had been quite abundantly present in the case of the Health of the Doctor, as there is a well-defined category of statistics concerning the health of general practitioners in the compilations of the Registrar-General's Office, but there is no category of medical students.

Sir James Paget's Analysis.

The only direct reference to the subject which I have been able to find is a very short paper by Sir James Paget, published in St. Bartholomew's Hospital *Reports* for 1869. Paget there considered the question under the heading, What Becomes of Medical Students? and his inquiry is not entirely limited to the stage of pupilage, nor is the chief attention given to the health of the persons considered so much as to their achievement. But out of a round number of a thousand of his own pupils whom he thus passes in review, 41 actually died during pupilage, 15 failed to qualify, and 96 relinquished the profession after beginning either its study or its practice. Of the 41 who died, 17 are recorded as suffering from tubercle and 2 committed suicide. It is interesting to note that 87 died after beginning practice, one of whom was hanged for murder, the notorious Palmer of Rugely, who, Paget remarks caustically, "was an idle, dissipated student, cursed with more money than he had either the wisdom or the virtue to use well." Paget began his paper with the remark that he was not aware that any attempt had been made previously to answer his question; and I have been unable, as I have said, to find any reference to the matter I am now considering since Paget wrote. I am hopeful, therefore, that the subject will not at any rate be a hackneyed one.

In the last annual report of the Ministry of Health (June, 1929) the statement is made that the sum estimated for the current year as being required to carry out the service of that Ministry is not less than £23,028,000, a sum which is nearly a million more than for the previous year. The value of these services rests almost entirely upon the fitness of medical men and women to perform the duties required, and the preparation of the army of practitioners who will be called upon to execute these functions becomes a matter of considerable public importance. When one considers the enormous increase in the complexity of the education of the medical student since Paget's time, and notably the extension of the actual duration of his training, one would perhaps surmise that the mortality of students, both as regards their relinquishing the profession as well as being invalided or dying out of it, would be materially increased.

Inquiry of Deans of Medical Schools.

Unhappily, it has been extremely difficult to get any reliable information upon these points. As a preparation for this paper I sent out a letter to the deans of all the principal medical schools in the British Isles, and I have received a large number of replies, which I shall roughly analyse. (1) A preponderant number replied that they had no data, and could not obtain them. (2) A considerable number replied that, while furnishing no actual figures, the writers were convinced that the mortality from illness amongst medical students was very small, quite a curious consensus of opinion placing it as "about 1 per cent." More definite information has been supplied by two schools, Leeds and St. Mary's Hospital. The following letter from the Dean of the Medical School of Leeds is reproduced with his permission.

Health of Medical Students at Leeds.

"I can only speak," he writes, "in general terms. Before the war I noted that the mortality or disability from tuberculosis was about 5 per cent.—*i.e., about one each year, in an entry* of 20. I do not remember any other cause of withdrawal. We lost no student by infectious disease or abdominal trouble, and certain cases of death from pneumonia occurred in students who had withdrawn for other reasons.

"Since the war there have been very few cases of tubercle, and some deaths from influenza and cerebro-spinal meningitis not to be attributed to the line of life. I have attributed the decrease of tubercular cases to the better conditions of student life, as all lodgings must be inspected and registered, and the facilities for outdoor exercise have increased vastly. Daylight saving and the decrease of monkeying about town in the evening may have had an influence, but it has to be noted that the tubercular cases pre-war occurred usually in students of very orderly lives in that respect.

"The student of the present day spends far more time out of doors, *and I note that there is much less difference in his condition* at the beginning and end of terms than there used to be. In pre-war days the student had little recreation without much trouble in transport. Now he can work in a game of tennis all the year round, or a game of golf, instead of crawling out to a pub. with a billiard table."

Withdrawal of Students at St. Mary's Hospital, London.

The following statistics have been prepared from a list of some 400 entries to St. Mary's Hospital Medical School between 1917 and 1924, the number of men and women students being approximately the same.

Number of students who, having entered upon a medical course, fail to qualify .. .. 9·3 per cent.
(Men, 13·5 per cent; women, 5·1 per cent.)

Number falling out at the various stages of the curriculum—
(*a*) Before completing the first exam. .. 4·9 per cent.
(Men, 7·6 per cent.; women 2·2 per cent.)
(*b*) Before completing the second exam. .. 1·7 per cent.
(Men, 2·5 per cent.; women, 0·9 per cent.)
(*c*) After completing the second exam., and before becoming qualified .. 2·7 per cent.
(Men, 3·4 per cent.; women, 2·00 per cent.)

Reasons for Withdrawal.

Men.—Of the 32 withdrawals dealt with during the above eight years, the following were the causes so far as can be ascertained.

(1)	Ill-health .. .. (Lung trouble, 2; shell shock, &c., 2; mental, 1.)	5
(2)	Financial difficulties	6
(3)	To take up good business openings	2
(4)	Failure to take an interest in the work	8
(5)	Suspended for misconduct	2
(6)	Uncertain (but not ill-health)	9

Women.—(12 withdrawals).

(1)	For the purpose of being married	6
(2)	Personal ill-health ("lung trouble")	1
(3)	Illness of relations	1
(4)	Suspension for unsatisfactory work	2
(5)	Uncertain (not ill-health)	2

It will be seen from these records that tubercle still seems to head the list of causes of death or withdrawal amongst medical students, and it is of some significance in this connexion to note the reply from Guy's Hospital, in which the statement is made that two house officers during the last five years were obliged to give up their appointments on account of tubercle. In only one reply has suicide been mentioned as a cause of death.

Comparison of English and American Systems.

The strenuous character of the present-day training of medical students, a training which involves very hard and continuous study for an average period of seven years between the entrance examination and qualification, marks out medical students as a class apart, and perhaps justifies my considering this question from this limited point of view. We have practically no statistics in this country of the health of students in general; but a considerable volume of literature from American sources upon this subject is now available, to which I shall refer in a few minutes. Health Education Service, as this has come to be named, forms a very important part of the administration of American universities and schools, and one cannot but regret that the subject has received no attention in this country where haphazard methods still rule. The American student nowadays is very carefully "vetted" before he is allowed to come to college, still more carefully examined for his physical fitness to undertake an industry or profession, and most severely of all for his suitability to enter upon arduous athletic exercises.

It will perhaps be contended that our system, which is lacking in all these features, succeeds by survival of the fittest, but this is surely a somewhat expensive and unscientific method of dealing with the circumstances involved. To wait, as is sometimes recommended by shortsighted observers, for treatment until the individual feels ill, which is still too much the habit with our people, is both unscientific and desperately uneconomical. Most sensible persons nowadays make a point of visiting their dentists two or three times a year, even in the absence of symptoms of toothache; and the same precautions should obviously be followed in other departments of medical practice. It is, I think rightly, contended by the advocates of the American careful methods of examination at college that the young people who have been through this mill become apostles of health and spread far and wide more scientific conceptions as to the care of mind and body than prevail amongst those not so instructed, and a still further ultimate advance in the high standard of health amongst the American population may be confidently anticipated. The American universities, where co-education is the rule, also supply some data on the relative resistance of men and women to wear and tear of training for professions generally. In our schools, where co-education is much more recent and on a very much smaller scale, no sufficient data are available.

---

* An address given at the Royal Institute of Public Health on Oct. 16th, 1929.

The time is ripe, I think, for a consideration on broad lines of the health of students in general, both in secondary schools and in universities, and it is an anomalous fact that his consideration is given very meticulously in the secondary schools which are under State or municipal control but hardly at all in the great public schools of the country and in the universities, both of which categories are under voluntary management as distinguished from State or municipal management. There is no brighter outlook for the operation of preventive medicine than in this particular function of watching over the health of the adolescent and the young adult. The results obtained from the care given by the State to this function are so encouraging as to force upon us the conviction that medical watchfulness should be exercised in all departments where young people are undergoing a community education, whether at the expense of the State or of the individual. Some interesting comparisons have been made of the physique of public school boys as compared with boys attending State schools, and hitherto the comparison has been in favour of the public school boy who obviously starts with greater advantages, coming as he does from well-to-do households as compared with relatively poorer surroundings. But the later examinations are more and more proving that the State-educated adolescent is fast catching up, and even surpassing, the public school boy in this matter of physique. That some of the conditions of life at public schools require radical alteration was borne in upon me by a recent professional experience. I was consulted about an outbreak of body ringworm in an old-established house at one of the greatest and most famous of our public schools. The house contained 40 boys, all of whom were found to be infected, and the matron and housemaster, whom I interviewed, admitted that it was the rule, owing to the paucity of bath rooms in an old-fashioned house, for ten boys to use the same water one after another, and the promiscuity which such conditions inevitably engender very amply explains the overwhelming character of the epidemic in that particular house.

American Health Service.

The care taken by American colleges in sifting students before entry has no counterpart in this country, and I submit that we have much to learn from American methods. Although the American Health Service, as it is called, is of comparatively recent establishment, some valuable data have already been afforded. It is interesting to note that the principle was in the first instance initiated nearly half a century ago by the enterprise of some women investigators who were concerned to find that women students compared unfavourably in health conditions with men, and proceeded to ask why. Periodical medical examinations and careful "vetting" of women students began at once to make a difference so perceptible that the men copied the idea. Very much of the high health standard of the American people is due to the coöperation and intelligent watchfulness of women who, during the last 30 years, have learned from their college days to busy themselves as housewives, with the nutritive value and the purity of foodstuffs, and by unity of action through the agency of leagues or unions of consumers throughout the country have been able to insist upon the supply of better food. To quote one item only, the quality of American milk is immeasurably better than the quality of milk sold in this country, and I understand that probably as a result glandular tuberculosis is non-existent in the United States.

These health services have spread all over the colleges of the United States. Here are some examples of what is done. At a great industrial college in the United States inquiries are made of intending applicants for entry (1) whether the applicant should come to college at all; (2) what form of industrial occupation he may be physically fitted to undertake if admitted; (3) how he may improve his physical condition so as to make the most of his opportunities both in industry and at college; and searching inquiries upon these subjects are made through the medium of family practitioners, whose coöperation is usually readily obtained. Several interesting facts have become apparent from a study of these American statistics. In a prominent women's college, for example, the unexpected finding was that women students tended to show an actual deterioration of health during college life as compared with the men in a similar college. The figure quoted states that the women dropped 10 per cent. while the men gained 6 per cent., a contrast explained by the writer as being due to the women taking their work too seriously, and he forms the pessimistic axiom: "the higher the intellectual attainment in the subjects of health and disease, the lower seems the health intelligence. The greater the theoretical knowledge of health, the poorer seems the practice."

Another index to the value of leisure and healthy exercise is afforded by a comparison of the health of self-supporting students, that is to say, students who maintain themselves by other occupations during their study, a feature much more common in American than in British colleges. The health of students thus working overtime, as it were, compared unfavourably with the health of students who were not so handicapped, and illness in women of this class was more than twice as large as in men of the same class.

University of Minnesota.

In the University of Minnesota, with a student body of 10,000, of whom about half are stated to live at home, the health service is a very elaborate and important part of university administration. Its expenses are partly met by a compulsory fee exacted from each student, constituting about half of the actual expense of the service. The completeness of provision for overhauling disease actually provided in this University[1] is indeed remarkable. A very efficient medical service on a part-time basis has been developed and is under the direct control of the President of the University through a subordinate officer called the Director of the Health Service. The examinations conducted by this service include entrance physical examinations, periodic health examinations, and special physical examinations. Defects and abnormalities which are discovered by the entrance examinations are followed up during the school year with remarkably beneficial effects in a series of departments, such as general medicine, eye, ear, throat, &c. An improvement in defects averaging 60 per cent. was noted. Special physical examinations are exacted of students who wish to participate in athletics, and the American student is thus very thoroughly "vetted" for the particular form of athletics which he may wish to practise. An extensive out-patients' service forms part of the machinery of defence against disease, and ample provision is made for infirmary treatment, the compulsory fee covering a certain measure of infirmary treatment every year. Vaccinations, immunisations, immunity tests, are extensively used. One of the most important and typical of the measures taken in this service is the careful watch kept upon nutrition; observation is made of the student's diet, and his habits of eating, sleeping, recreation, worry, work, &c. The provision of medical services upon the spot naturally effects a great saving of time, and the accessibility of the departments may be gauged by the use which the students make of them. For example, during the year 1925–26 about 1800 students made 8772 visits to health departments, exclusive of the entrance dental examination which is one of the largest departments in the University. The number of hours per week actually given by the medical staff is comparable to the service at a great teaching London hospital.

University of Cornell.

Another valuable contribution is in a paper[2] upon the organisation of health education at Cornell University, New York, by the medical adviser, Dr. D. F. Smiley, who states that for the last three years each entering class at Cornell University has shown progressively fewer physical defects and faulty health habits than the preceding class. The means adopted at Cornell University are very fully detailed in this paper, and the sense of responsibility towards the students entertained by the University authorities is clearly very much better developed than it is with us. There can be no question also that, as Dr. Smiley remarks, these inquiries furnish the most admirable opportunities for research in the field of health-education amongst students in general, and should furnish also data for estimating the incidence, and perhaps the causes, of numerous minor disorders—colds, glycosuria, the effect of exercise upon minor abnormalities of the heart and vessels, &c.

The actual institution of these services at Cornell dates from 1919, so that they have now had ten years working of the full programme, but hygiene had been a subject of instruction at Cornell since its foundation in 1868. The department is under the control of a committee of four members appointed by the President of the University who retains a coördinating control. It is operated by physicians, and it has been found that full-time physicians are preferable to part-time physicians; that men physicians are preferable for men, and women physicians for women; that young physicians are better than old ones; and practical experience has shown that there is enough work to employ one physician for every 500 students, and it is hinted that this proportion must be soon increased. The activities of the Department of Hygiene are described under five headings: (1) health examination; (2) medical consultation; (3) communicable disease control; (4) health education; (5) research. Every undergraduate and every entering graduate is required to have annual physical examination. No athlete is permitted to represent the University on an athletic team without having qualified for and procured a certificate from the medical adviser's office. Medical services are open daily from 9 A.M. to 6 P.M., and something like 25,000 voluntary consultations are recorded per year. Each student pays $5 a term for the services, which includes the free use of the University infirmary in cases requiring bed-treatment.

[1] Journal of Preventive Medicine, 1927, p. 377.

[2] Public Health Reports (U.S. Public Health Service), 1926, 2631.

The value of this method is demonstrated by the experience of an epidemic of influenza occurring in the year in which the report was written. Early treatment, rendered practicable by these conditions, of 658 cases of influenza resulted in keeping the incidence of pneumonia after influenza to less than 1 per cent. of the total number of cases, an incidence which compares very favourably with the usual statistics of influenza. These careful measures further allow of the compilation of extremely useful statistics. Lost time during the year amongst 3724 men students was 1·1 per cent., and amongst 1173 women it was 1·8 per cent., figures which compare favourably with an earlier inquiry at Cornell by Dr. Emerson in 1919–20, when the loss of school hours was for the men 1·5 per cent. and for the women 2·4 per cent., and this is notwithstanding the disturbance of the statistics occasioned by the very severe influenza epidemic in 1926.

The Life Extension Institute.

The actual monetary value to the State of the improvement in the health of individual citizens resulting from periodical medical inspection is demonstrated in a series of papers contributed by experts in life insurance, a subject much more carefully and scientifically studied in the States than here. A group of men prominent in American public life, including Surgeon-General Gorgas of Panama fame, ex-President Taft, Dr. Fisk, and Dr. Ley, in 1914 started a scheme of periodical health examinations conducted under the auspices of an institution founded by the group and called the Life Extension Institute. The services of this body were taken advantage of in the first instance by the great insurance company, the Metropolitan Life Insurance Company of New York, and a very significant review of the results obtained after six years' experience is contributed by Dr. Storey. During that period the company had medically examined on this system of periodical examinations about 6000 people at a cost of $60,000, and had gained, through the premiums of persons whose lives had been extended as a result of these examinations and the correction of minor defects, no less a sum than $120,000; the company had thus made 100 per cent. on its investment, and its example was speedily followed by numerous other insurance companies, so that it is stated that the Life Extension Institute has examined over half a million patients since its inception. A consideration of nine years' operation of these services showed a reduction of 18 per cent. in the death-rate of policy-holders affected, and amongst a group of impaired lives a reduction of over 50 per cent. in the death-rate. With the typical American business grasp, in another paper the capital value of this improvement in health is carefully assessed and set out. The money-equivalent of this improvement is estimated at no less a sum than 3150 million dollars in the year 1924. The figures are based on the estimate of the value of the individual to his or her family or dependents, and upon this basis the curious comparison is made that while in 1922 the material assets, other than this human capital, in the United States was 321,000 million dollars, the human capital upon the principle just described was, in 1924, nearly five times as great, and the business value of this system of health service is thus very abundantly demonstrated.

II. CONDITIONS OF WORK.

With regard to the conditions of work of medical students, which is the second title of my paper, these have changed so radically, even since the time of Paget, as to make comparisons difficult between the present-day conditions and those of earlier years. Unhappily the transcendent genius of Dickens has stamped his presentation of medical student life in the persons of Bob Sawyer and Ben Allen upon the minds of successive generations as being typical of medical student life in general. Even in Dickens's day this picture must have been a caricature, and no other picture has been drawn upon the same subject with any distinctiveness or force since he wrote the immortal "Pickwick." With the exception of some slight sketches by Conan Doyle the medical student does not seem to have figured since that date in English literature. The preparation for the profession of medicine has become so arduous and so absorbing that the medical student is kept to the grindstone very completely throughout the long seven years which form the average period of study. Nevertheless, it has become apparent from a study of the meagre statistics available that health conditions have improved very considerably, even in England. Housing of medical students, though still too little thought of, is immeasurably better, especially in the case of the big towns. As mentioned, the Dean of Leeds University regards the improvement under this heading as being largely responsible for the better general health of medical students noticeable even since the war.

The life of the medical student in the London schools differs very considerably, and must differ, from that of the fortunate student at the older residential universities. It is one of the disadvantages of the excellent training given in London that the student is restricted to intercourse with his own fellows and is not, as at a university, very easily able to mix with students of other faculties. This restriction, while mischievous in some respects, engenders in the student an extraordinarily ardent, if narrow, patriotism for the school at which he has been educated. To a member of a London school, such as Guy's or St. Bartholomew's, his hospital and all its interests acquire almost the force of a religion, and the friendships made in this narrow environment are often lifelong and abiding. Indeed, it is something of a reproach that there is so little understanding of or sympathy with other schools on the part of the students of one school. A rigid favouritism is apt thus to grow and to be reflected in the phenomenon that it is seldom that the choice of members to fill vacancies on the staff goes outside the magic circle of the school, a condition of things which is happily breaking down at present under the stress of new university appointments, now made by the University of London, with the financial help of the University Grants Committee.

Study and Relaxation.

With the drive exercised by the necessity of passing an ever-increasing number of increasingly difficult examinations the conditions of pupilage have changed very notably. It is no longer possible, as it was when I was a student, for a man to remain, as one of my fellow-students actually did, at his hospital for more than 18 years, at the end of which period he had not taken his first qualification. Much more control is exercised now upon the work of the student, and the incorrigibly idle or incompetent student is asked to leave his hospital after a certain period of probation if he should have failed to mend his ways. It is not surprising that with so persistent and so harassing a study the need for relaxation in sport and other outlets for energy is greater in the case of the medical student than perhaps in the case of any other class, and the cultivation of athletics has almost gone beyond reasonable limits in many medical schools, where the prizes of resident appointments are often given more for athletic prowess than for academic distinction. The rebound of the medical student from close application is sometimes a little exuberant, as for example in the regrettable incidents which recently attracted the notice of the London police-courts when medical students disturbed the proceedings of an antivivisection meeting. But the astonishing sobriety and restraint of medical students of the present day as a class offers indeed a sufficient contrast to the attitude of mind depicted by Dickens, and to the general conception of medical students still prevailing with a large number of people.

Medical study has become in our own generation completely transformed by the advance of medicine in its scientific outlook. With the immense increase of scientific discoveries new subjects have been continually added to the curriculum, and at the present moment the medical student has to be "signed up," as it is called, that is, certified as having attended, classes in something like 40 subjects. There seems to be no finality in this accretion, and it has long been obvious that certain changes are necessary in the preparation of the student. The period of study, which now approximates to seven years, cannot well be extended; some rearrangement of subjects must therefore come about. The present duration of the training requires so large an expenditure of time and money, both on the part of teaching schools and of students, that the profession of medicine is becoming more and more restricted to those who start with considerable private means and who enjoy an unusual degree of vigour and ability, and doubtless this latter feature accounts for the relatively small mortality; the student is a picked student from the beginning.

Numbers Seeking Entry.

It is interesting to note the variation in numbers seeking entry into the profession. Thirty years ago the average entry in the British Isles had been about 1800. It dropped during the next decade and a half to something like 1400. During the war the wastage of doctors and the demand for their services at the Front led to a somewhat unnecessary alarm on the part of the public that the profession might become dangerously depleted, so that by the end of the war the entry approximated 2250, and for two or three years after that date even exceeded this number, the peak figure being 3420 in one year (1919). During the past five years the entry has stood round these figures: 1043, 1070, 1260, 1214, 1363. With the exaggerated entry following upon the war, the number of new practitioners registering each year has greatly exceeded the pre-war figures, so that in 1928 the number of medical men upon the Register was actually 10,000 more than in 1918, and 20,000 more than in 1898. It may be said shortly that the number of registered practitioners up to the end of the first quarter of the present century was almost exactly double the number 50 years ago, but the population of Great Britain and Ireland in that period has not increased by more than about 50 per cent., so that the increase of population has been very much less than the increase of medical practitioners has been, and the ratio of doctors to population is much higher than before.

Much of the increase has been absorbed by the rapidly increased demands of public health work, and there is considerable prospect of these demands increasing and not diminishing; but it is clear that the medical profession, if not actually overstocked at the present time, runs some risk of being so. However, the prospect of obtaining work after so prolonged a preparation for it may, at the present moment, be said to be on the whole favourable. Much discussion has taken place during the past year as to the position of medical women, whose entry during the war years was disproportionately large as compared with men. Evidence is somewhat conflicting, but my personal impression, founded upon reliable data, is that a far larger number of medical women are earning a sufficient livelihood by medicine than the pessimists allow.

Prospects.

Whatever may be the future of the medical student, there can, I think, be little question that his training is now so far-reaching, so catholic, and so well selected, that the student who receives a medical training is thereby fitted for his life's struggle in any direction, more completely than any other member of the community. The success of medical students who forsake medicine and undertake other pursuits or professions corroborates this statement. Indeed it may be said that the medical man of to-day has much the best general education of any member of the community, professional or otherwise, and the rôle of the priest in the Middle Ages, when the priest was the only educated person amongst his fellows, is becoming transferred to the doctor, with repercussions both upon the doctor and upon the public which are producing some curious effects at the present moment. The desire and the search for health have become greatly extended; a much wider proportion of the people are actively interested in these questions, and at the same time woefully ignorant upon them. The function of educating this eager public has been assumed largely, not by instructed members of the medical profession, but by irresponsible and mostly anonymous newspaper writers, and there is considerable demand for an alteration of this state of affairs, a demand which is still difficult to supply; this is a problem which many leaders of the medical profession are considering at the present moment.

State Control.

All the political portents go to show that there will be an ever-widening provision of State medical service, which now absorbs more than 17,000 members of our profession, and many observers think the time is approaching when all the medical services will be State-controlled. The body entrusted with the inspiration and guidance of medical education, the General Medical Council, has been subjected to severe and usually ill-informed criticism, and in response to a certain clamour, Parliament added two or three years ago a lay member to the composition of that Council, which, by the force of circumstances and not by design, had become restricted to professional men. The admirable choice was made of Sir E. Hilton Young, M.P., who recently told me that he has been very favourably impressed, perhaps rather contrary to his expectation, by the judicial wisdom, more especially in its much criticised disciplinary function of the General Medical Council. A comparison of the status of the medical profession before and after the foundation of the General Medical Council must convince any impartial observer of the enormous value of its services in the half century during which it has been in existence. A very beneficent and recent activity of the Council has been its insistence upon better training in preventive medicine, an aspect of that art which is becoming more and more valuable. With the increased competition brought about by the large increase in members of the profession, there has been an increasing demand for the possession of university degrees as distinct from qualifications of licensing bodies not enjoying university status. There are now 11 universities in England and Wales with fully developed medical faculties, and the University of London alone comprises in its medical faculty no less than 12 distinct and competing medical schools. Some 20 years ago the medical schools were able to persuade the University Grants Committee that medical education as a technical subject was eligible for block grants from the Exchequer, and these subventions have become one of the main elements in promoting the stability of the schools. Perhaps, naturally, the grant-giving bodies at first sought to eliminate what they deemed the weaker schools, especially in London, but notwithstanding considerable pressure to this end, all the 12 schools have survived, and the competition is all to the good in ensuring an increasing effort to improve the conditions of life and opportunities of training of medical students. It may, I think, be said with confidence that the London medical schools generally enjoy a higher reputation at the present time than in any other within living memory.

Littré's Definition.

Fifty years ago Littré, in his great dictionary, gave a definition of medicine which showed an uncanny foresight of its present developments. He described medicine as "the art which has for its purpose the preservation of health and the cure of disease, and which rests upon the study of the science of disease, or pathology." The preservation of health, which Littré thus placed first, rather than the cure of disease, has become the absorbing motive of medicine within the last few years, and the function of the doctor in promoting the preservation of health has made him perhaps the most valuable artificer of the fortunes of our present-day civilisation.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 12TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 131 (last week 97); scarlet fever, 3060; diphtheria, 1582; enteric fever, 104; *pneumonia*, 809; puerperal fever, 50; puerperal pyrexia, 115; cerebro-spinal fever, 7; acute poliomyelitis, 20; encephalitis lethargica, 18; dysentery, 7; ophthalmia neonatorum, 100. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Oct. 15th–16th was as follows:—Small-pox, 166 under treatment, 8 under observation (last week 141 and 4 respectively); scarlet fever, 2263; diphtheria, 2069; enteric fever, 30; measles, 166; whooping-cough, 157; puerperal fever 30 (plus 14 babies), encephalitis lethargica, 125; poliomyelitis, 6; "other diseases," 20. At St. Margaret's Hospital there were 23 babies (plus 13 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 6 (1) from enteric fever, 11 (2) from measles, 4 (1) from scarlet fever, 21 (3) from whooping-cough, 41 (3) from diphtheria, 186 (49) from diarrhœa and enteritis under two years, and 29 (3) from influenza. The figures in parentheses are those for London itself.

The deaths from diarrhœa are on the wane, the highest figures being reported from Birmingham and Liverpool, each 14, Hull 13, Sunderland 8, Middlesbrough 6, while Glasgow, Dublin, and Belfast reported 0, 9, and 4 respectively. The deaths from enteric fever were reported from Brentford and Chiswick, Portsmouth, Huddersfield, Halifax, and Newcastle-on-Tyne, each 1.

The number of stillbirths notified during the week was 274 (corresponding to a rate of 42 per 1000 births), including 54 in London.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL.—On Monday, Nov. 4th, Princess Louise will lay the foundation-stone of the first block of the new Queen Charlotte's Hospital in Hammersmith.

Harveian Oration

ENTITLED

CIRCUMSTANCES IN THE LIFE AND TIMES OF WILLIAM HARVEY.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1929,

BY SIR WILMOT HERRINGHAM, K.C.M.G., C.B.,
M.D. OXF., HON. M.D. TRIN. COLL., DUB.,
FELLOW AND SOMETIME CENSOR OF THE COLLEGE; CONSULTING PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL; LATE VICE-CHANCELLOR, UNIVERSITY OF LONDON.

IN such a quest we look first into a man's own writings. Of Harvey's Discourses you have heard enough. They shed a certain light on his character, but hardly any on the events of his life. Such as it is, all is well known to you already. From private letters we expect more. But of the few of Harvey's letters which are preserved, several refer merely to anatomy and add nothing we did not know. One, *it is true, that to Dorchester, better known as* Sir Dudley Carleton, shows that, however careless Harvey may have been about business, he, at any rate, took care not to lose a good position when he had got it.

Lastly, there remain the letters to Lord Feilding, later the Earl of Denbigh, and a rather incompetent Parliamentary General. They are priceless, for they show Harvey in a new character as the discontented British tourist. He is perfectly true to the type. He is detained in quarantine at Treviso, and he is furious with the wooden stupidity of the officials who will not let him through, he is furious at the quarters in which they have housed him, and he is more furious still at their daring so to molest an English gentleman of no small importance.

The chief passages in Harvey's Life are well known. They have been collected by Sir D'Arcy Power, and Sir Thomas Barlow added an account of his University years. I may, however, give you a few which I do not remember to have seen mentioned.

In 1625 the Duke of Buckingham was accused of poisoning King James by a plaster applied to his arm. Harvey was examined before the House of Commons. He had been in attendance during the King's last illness, had been present when the plaster was applied, and did not know what it was made of, but he saw no ill-effects from it. He was one of a committee of this College which, in 1627, reported on some alum works in the parish of St. Botolph and *condemned* them as a nuisance.

In 1633, on June 23rd, when he was with King Charles for the coronation in Holyrood, he received the freedom of Edinburgh and was made a Guild brother at the banquet given to the King by the city.

In 1641 he went to Aberdeen, and on August 28th received the freedom of that city. This was the year in which Charles tried unsuccessfully to raise a Scotch force against Parliament. It was not, I think, known before that Harvey accompanied him on this occasion, as well as in 1630 and 1640.

In 1644 the King sent the Duke of Richmond and Lennox and the Earl of Southampton as Commissioners to treat for peace at Uxbridge with the Parliament. Harvey went in the suite of the Duke of Richmond and Lennox, with whom he had travelled in France 14 years before, and his friend Edmund Smith went thither also in the suite of the Earl of Southampton.

In November, 1646, he was given a pass from Oxford to Newcastle to attend the King as his physician. But he did not follow the King to Holmby House, nor do we find that he was ever again in attendance. Charles was never out of health, as we know from Sir Thomas Herbert, during the remainder of his life, and no physician was among the few servants who were allowed him.

In 1650 Harvey was given a pass to go to London to attend his old patient, Lady Thynne. She had to guarantee that he would take no steps prejudicial to the Commonwealth, but that was merely the usual precaution observed with anyone who had been with the late King.

David Lloyd, in his Memorials of certain persons who suffered during the Rebellion, published in 1668, states that Harvey was fined £2000 by Parliament.

THE FAMILY.

Harvey's next brother, John, was Sergeant or head of one of the departments in the Household, became on his resignation Receiver of Crown Lands in Lincolnshire, and died in 1645 Member for Sandwich. His executor was the younger Harbottle Grimston, one of the most respected of the Parliamentary party.

The five remaining brothers were all in trade. Two of them, and apparently only two, were in the Grocers' Company. Daniel was elected in 1611, when he was only 24, and was given a loan of £50 out of a benevolent fund founded by the Company to start young members in trade, and Eliab, was elected in 1616. Both held office, and Daniel was elected Sheriff and Warden, but paid the fine to escape service. Foreign trade was then in the hands of chartered *companies. The chief exports were cloth, a trade as* old as Charlemagne, lead and tin. The oldest was the Merchant Adventurers Company, which had the monopoly of the trade with the North Coast of Europe from the Elbe to the Scheldt. Their books are lost and we cannot therefore tell if the Harveys were in it. But there was a smaller company of Merchant Adventurers trading with France, of which Daniel and Matthew were certainly members.

In 1627 Charles, in one of the vagaries of his senseless foreign policy, confiscated some French ships. The French retaliated by confiscating British goods in France. This led to litigation, and Daniel and Matthew were accused before the Privy Council by their fellow Adventurers of acting in collusion with the French merchants. The matter seems to have dropped as no subsequent proceedings are recorded. The other two great companies were the Levant Company and the East India Company. The Harveys were in both.

It seems to have been a family characteristic to refuse to pay entrance fees. In 1616, Thomas and Daniel, partners and "Farmers of the pre-emption of Tynne," were admitted to the Levant Company. Thomas paid his "fine," as it was called, of £25, and this admitted the firm. Daniel was abroad. But when Thomas died in 1623, aged 38, Daniel, by the rules of the Company, became liable for a fine. *Nothing* would induce him to pay it, and the Company did not get it out of him till December, 1625. Eliab and Michael did not join till 1637, when the fine was £50. They also refused to pay, and haggled for months with the Company until they obtained an abatement. They repeated the process in the East India Company. Daniel was already a member in 1624. Eliab, Michael, and Matthew were elected in 1628. "The fine was left to their discretion though it was considered that they could not give less than £10 to the poor-box." They not only could, but did. At the next meeting "they took the accustomed oath, the court expecting from them some reasonable fine in that respect, but they presenting to the Court but £6, which, howbeit, they refused not, yet they wished that Daniel Harvey would acquaint his brothers that the Court expected they would have enlarged themselves in a more bountiful manner, for the favour conferred upon them is not usually permitted to any under £20 a man."

In 1633 there is a delicious bit of sharp practice by Daniel. When a ship came home the members bid for the cargo, and the payment was due some months later. The usual rate of interest was then 7 per cent., and Daniel moved that the Treasurer should be ordered to receive such moneys as he should bring in upon discount for pepper at 8 per cent., on the grounds that it was much better for the Company to

5540

receive its own money at 8 per cent. than to borrow outside at 7 per cent. The Treasurer, however, took a different view and threatened to resign. It is not surprising to find that the Company supported him.

Clarendon, in his "Life," states that Daniel had the reputation of knowing more about trade than any man in England, and that Archbishop Laud, when he was made Commissioner of the Treasury in 1636 on the death of Weston, consulted him frequently. They were near neighbours, as the Archbishop had a house at Croydon and Daniel lived at Combe near by.

There is further evidence on the reluctance of the Harveys to part with money. When the Civil War broke out both Parliament and the King found themselves in great straits for money. Both, at first, raised it by voluntary contributions and the King never had much from any other source. Parliament, very early, began to exact contributions and their first essay was by the methods in vogue in former reigns. The levy of one-twentieth was ordered on all goods and movables. Under this Daniel Harvey was assessed in Dowgate ward. In April, 1643, he was ordered to pay £1500, but in November this was raised to £5000. The money was extracted from him with great difficulty. In May, 1644, he was imprisoned at Lambeth House. In August they threatened to deport him to Plymouth. By Dec. 20th he had paid £3000. In February, 1645, he is ordered to pay £500 more within a fortnight, and in July he was brought up before the Commissioners to answer objections against him. In 1650 he died, and in 1652 Eliab, his executor, made an affidavit that he had paid £4000, whereas his rightful share was only £1360, and his estate was thereupon credited with £3000 on the Public Faith—corresponding to our funds. Eliab was assessed at £2500. He absconded for a time. His goods at Roehampton were distrained but were bought up by his brother-in-law, Colonel Francis West, afterwards Lieutenant of the Tower for Parliament. Eventually he was brought up in custody and forced to pay up. The brothers were not alone. Many citizens behaved, and were dealt with, in the same way. Later, Parliament raised money by assessment on counties, also an old method, and great difficulty was always experienced in collecting it. The continual arrears in pay were what gave the Army its power, as it refused to be disbanded unless payment was made and no money was available for the purpose.

But the Harveys did not confine their operations to pepper and currants. In later life they dealt largely in land. Land was then easy to buy. All the royal lands, all the episcopal lands, and all the cathedral lands were up for sale. Parliament also dealt very hardly with the Royalists and only admitted them to composition for their property under heavy fines. A man with a rent roll of £1000 was usually fined £2000. As he had already spent all he had, and melted his plate for the king, and as there were then no other ways of investing money than in land, he could not pay his fine without selling some of his property. To sharp business men like the Harveys it was a great opportunity. They evidently acted together, for the brother who becomes the owner is often not the ostensible purchaser.

By the end of the first generation, therefore, the Harveys, including William, had become large landowners. Matthew, who died in 1642, owned land in Kent and Surrey, Michael's sons had a Dorsetshire estate worth £21,000, Daniel had Combe and property in the Midlands and elsewhere, and left his widow £1200 a year besides, and Eliab had Roehampton and Chigwell and a house in Broad-street, besides other properties, and left also £1500 a year to his widow.

Only two of the branches lasted long. William, John, and Matthew had no children. The Michael branch died out in 1712. Thomas's only son, known as John Harvey of Antwerp, I have been unable to trace.

Young Daniel married into the Montagu family which took a leading part in bringing back Charles II. He obtained with his wife Combe Neville, an estate adjoining Richmond Park, was a member of the Convention Parliament of 1660 which voted the Restoration, was knighted by Charles the first day he landed, along with young Eliab, his cousin, and obtained a grant of arms which, up to that time, the family did not possess. He was a courtier, was made Ranger of Richmond Park, was a friend of the notorious Castlemaines, and died as Ambassador at Constantinople in 1672. His son Edward, of Combe Neville, was a Jacobite and wasted his fortune. In 1750 Edward's surviving son sold the property. Daniel's sisters married well. Elizabeth married Heneage Finch, an honest man and an excellent lawyer, who became Lord Chancellor and Earl of Nottingham. Mary married Sir Edward Dering, of Surrenden Dering, and Sarah married an Irish peer, Lord Bulkley.

Young Eliab remained in business, and in 1672 was proposed, though not elected, for Governor of the Levant Company. He had a great house in Broad-street which just escaped the Great Fire, and was made keeper of the King's game in Epping Forest, where one of his properties, Chigwell, was.

He was succeeded by a long line of Williams and Eliabs, who were country gentlemen and M.P.'s—in the Parliament of 1678 there were no less than four members of the family—with occasional soldiers. The last of the line was a distinguished sailor, Sir Eliab, who, when a midshipman, nearly lost the property at the gaming table, commanded the *Temeraire* at Trafalgar, and in 1800 was cashiered for insulting his admiral, Lord Gambier, who had promoted Cochrane over his head. He was restored, however, the following year and died in 1830, G.C.B. and Admiral of the Blue. He left no son and, through one of his daughters, Rolls Park at Chigwell descended to the late Sir Francis Lloyd, whose widow still lives there.

THE TIMES—SCHOOL AND UNIVERSITY.

Let us now consider some of the conditions of Harvey's own life. He was brought up at the Cathedral School of Canterbury, one of the best in the country. At that date Latin was the universal language. It was the language of learned men, the language of diplomacy and of travel. Every bachelor of divinity had to preach in Latin, the young barristers used it in their moots in the Inns of Court, the accounts of the Royal household and even some of the merchants' accounts were kept in it. Accordingly it was the aim of every good school to make its boys not only able to read, but able to speak Latin, and in the statutes of Canterbury dated 1541 it is ordered that the boys, whether at work or play, should speak nothing but Latin and Greek, but Greek was rarely taught in schools. You may remember that Montaigne, who lived about that time, was not allowed to speak any language but Latin until he was six. Greek was brought into the schools by the Calvinists who returned to England on the accession of Elizabeth. For them Greek and Hebrew were the two sacred languages, and for the study of the Bible Greek became common in the schools and even Hebrew was sometimes taught.

We may therefore confidently suppose that Harvey went to Cambridge able not only to read, but also to speak Latin after a fashion, and with some knowledge of Greek. The old free University had given place to a system of Colleges and Halls founded to train priests by pious benefactors, of whom the greatest, though not the first, was my own founder, William of Wykeham. The life was hard and the teaching narrow. Into these ecclesiastical seminaries the classic revival of the fifteenth century in Italy, patronised by Humphrey, Duke of Gloucester, and other great men, brought a fresh inspiration. At Oxford, Linacre and Grocyn were as good Grecians as any in Europe. Wolsey and Fox and Henry VIII. all encouraged and endowed Classical studies. But the Classics, and especially Greek, were attacked for their Paganism both by the old religion and the new. In Oxford, Greek soon fell into contempt. At Cambridge, under Cheke and Smith, it held better. By Harvey's time it was re-established. Spenser, who went up in 1570, was a Platonist, and Harvey was devoted to Aristotle.

But meanwhile the universities had fallen on evil times. The Church had been plundered by the Crown and also by its own patrons, both lay and ecclesiastic. Spenser, in Mother Hubberd's Tale, describes the lay patron bargaining with an unfortunate clergyman, before he would present him to a £40 living, that he should resign half the income to the squire's son. The case of Wokingham was reported to the Long Parliament. It was in the gift of Salisbury. The Dean and Chapter had leased the rectory and tithes to a layman, there was no vicarage, and the parishioners had, for many years, to pay a preacher out of their own pockets. The upper clergy were Pluralists. One man might hold several benefices. The lower clergy were accordingly half starved, and as a natural consequence were grossly ignorant, careless of their duties, and sometimes drunken and corrupt. Scandalous benefices beget scandalous ministers. It was this state of things that gave the Calvinist attack such strength. The Church fell as much by its own faults as by the virtues of the Calvinists.

The absence of decent prospects in the ministry led to a great falling off in the number of students. Added to this the destruction of the monasteries had deprived the universities *of* the large numbers of scholars whom they sent up with exhibitions. In the middle of the sixteenth century the numbers had fallen to a few hundreds, nearly all the halls were closed, and the colleges were half empty. Further, the ecclesiastical character of the universities laid them open to interference by the Head of the Church, now the Monarch. By voting for the divorce they had placated Henry VIII. But under Edward VI. all the heads and professors who sympathised with the old religion were expelled. Under Mary the process was renewed in the opposite direction. Eleven heads were expelled in Cambridge alone. Under Elizabeth the Act of Supremacy was enforced, with a similar expulsion of all Romanists, and the universities became violently Calvinist.

In 1578 the Vice-Chancellor of Cambridge and two other leading Dons broke into Caius College and destroyed all the decorations with which Caius, who was a High Churchman, if not a Papist, had beautified the Chapel. In 1595 Whitgift, the Archbishop of Canterbury, and a synod of bishops drew up the Lambeth Articles, of which the following are specimens:—

> 1. God, from all Eternity, hath predestined certain men unto life: certain men He hath reprobated.
> 2. The moving cause of Predestination unto Life is not Faith or Good Works or "anything that is in the person predestinated," but only the Goodwill and Pleasure of God.
> 3. There is predetermined a certain number of the Predestinate, which can neither be augmented nor diminished.
> 4. Those who are not predestinated to salvation shall be necessarily damned for their sins.
>
> * * * *
>
> 7. Saving Grace is not given . . . . to all men by which they may be saved if they will.
> 8. No man can come unto Christ unless the Father shall draw him; and all men are not drawn by the Father.
> 9. It is not in the will or power of everyone to be saved.

This cheerful view of the future was, however, too much for Elizabeth. She sent for her little black husband, as she called Whitgift, and, after giving him what, in those days, was called a rattling, told him to withdraw the Articles altogether, which he had to do. James, who loathed the Scotch Calvinists, threw all his weight on the same side. In 1011 Laud, who, in spite of the violent opposition of the two Abbots, George the Archbishop and Robert, Master of Balliol, had led a growing High Church party in Oxford, was elected President of St. John's, and by 1022 Oxford had become anti-Calvinist. Cambridge followed suit, though considerably later.

Meanwhile, however, a great change had taken place in the material circumstances of the universities. Elizabeth, who loved to air her accomplishments, began the system of Royal visits to the universities with all their solemn puerilities, which was continued by James and Charles. She made the universities fashionable. Donations were made by her courtiers, and the numbers rose, at the end of her reign, to 2500 at Oxford and nearly as many at Cambridge. Venn says that 1590 to 1640 was the zenith of the universities until quite recent times. The result was not an unmixed blessing. The rich youth who now flocked in brought with them the manners of the Court, and for many years the Statute books are full of decrees against extravagance in dress, drunkenness, gambling, insubordination, and such unseemly sports as football. An undergraduate twice convicted was to be whipped. Simmons D'Ewes could find no fit associates in 1018 but a few Dons.

All this had, however, little effect upon the poorer students. Their life continued as hard and scanty as it was before. Harvey went to Caius with a Matthew Parker scholarship. The capital endowment of it was £61 13*s.* 4*d.* Elizabeth, in 1559, made an injunction that all clergy whose benefices were worth £100 or more should, for every £100 of their income, contribute £3 0*s.* 8*d.* as an exhibition for a scholar at the universities. Under James existing professorships received additional revenue, among which the Chair of Physic at Oxford was augmented by the Mastership of Ewelme Hospital, and fresh chairs were set up in Mathematics, in Natural and in Moral Philosophy, and in Anatomy. All these at Oxford. Similar improvements, no doubt, took place at Cambridge.

During the Rebellion both Universities were at first Royalist, for Cambridge was preparing to send its plate when it was prevented by Cromwell, but Scarborough was expelled from Caius for his loyalty, and the University had by this time been overpowered by the Parliament. Oxford was loyalist throughout, and after the King's death refused to take the oath prescribed by Parliament, for which it was punished by a visitation under Philip, Earl of Montgomery and Pembroke, the Chancellor who succeeded Hertford. On his death in 1050 Cromwell became Chancellor, and under his tolerant rule Oxford had comparative rest.

Of Harvey's feeling to Cambridge we know nothing. He is not known to have returned there after taking his degree, though, as he was at Newmarket in 1030 attending the young Elector, it is possible he was present at some ceremony.

THE SCIENCES: MEDICINE.

To understand the England of Harvey we must imagine a society to which science was unknown. To us the growth of knowledge by observation and experiment is a common-place. Every morning we read the discussions of some scientific conference or are informed of a new discovery. In Harvey's time the few sciences that existed were little removed from magic, and the great majority, including all the biological sciences from botany to sociology, did not exist at all. Alone in the great mind of Bacon had the real meaning of science been grasped, and the immensity of its future conceived. Men still ascribed the action of the brain and liver to spirits, and the causes of disease to disordered humours. Not only had they not yet comprehended that such operations could be examined by physical methods, but they resented as heresy little less than criminal all attempts to correct the mistakes and supplement the deficiencies of great predecessors such as Galen, which would have been welcomed by no one more warmly than by Galen himself.

Chaucer does not give a very good character to his Doctour of Physicke.

"In all the world ne was ther non him lyk
To speak of physik and of surgerye
For he was grounded in astronomye,"

and therefore could tell his patients' prospects by the stars.

> "He knew the cause of every maladye
> Were it of cold or hete or moist or drye
> And where they engendrid, and of what humour;
> He was a very parfight practisour."

Then he describes his understanding with his apothecaries.

> "For eche of hem made other for to wynne
> Here friendship was not newe to beginne."

Then he describes a list of the old authors that he knew, and goes on to describe his rich dress.

> "And yit he was not esy in dispence,
> He kepte that he won in pestilence,
> For gold in phisik is a cordial
> Therefore he lovede gold in special."

Bacon, in his "Advancement of Learning," published in 1604, the year that Harvey took his degree, describes with great shrewdness the difficulties of medical practice, and sums up:—

> "So then the subject being so variable hath made the art by consequence more conjectural, and the art being conjectural hath made so much the more place to be left for imposture.
>
> "And therefore I cannot much blame physicians that they use commonly to intend some other art or practice which they fancy more than their profession. For you shall have of them antiquaries, poets, humanists, statesmen, merchants, divines, and in every of these better seen than in their profession; and no doubt upon this ground, that they find mediocrity and excellence in their art maketh no difference in profit or reputation towards their fortunes.
>
> "Medicine is a science which hath been, as we said, more professed than laboured, and yet more laboured than advanced,"

and the reasons that he gives are "the discontinuance of the ancient and serious diligence of Hippocrates" in taking notes of cases, the neglect of morbid anatomy, and the absence of exact inquiry into the effect of drugs.

In Bacon's own lifetime two men, Mayerne and Harvey, partly, we may think, owing to Bacon's criticism, and partly, no doubt, because they shared in the scientific spirit that was just beginning to awake, worked exactly as Bacon advised. We have Mayerne's clinical and post mortem notes in his own beautiful handwriting here in the Library. Harvey's, to which he himself alludes, are unfortunately lost, but he had them in 1648 when the letters to Riolan were published, and it is possible they may yet be found. They revived the old Hippocratic tradition, and they were followed, after the Restoration, by Willis, Lower, Glisson, and Sydenham.

It is difficult to judge exactly what Harvey's position was in the general estimation. He attended Bacon himself, and also his successor, Lord Keeper Williams, Bishop of Lincoln, and the latter's biographer, Bishop Hacket, tells how "that great secretary of nature, Dr. William Harvey," saved William's life in what seems to have been a dangerous attack of enteric in 1624. We know the names of other patients, Sir Thomas Thynne and Sir Thomas Sandys, from certificates that he gives of their unfitness to travel. He also attended the Lord Treasurer Weston who was laid up with an attack of the stone at York during Charles' expedition to Scotland in 1633. He says he lost practice by publishing the De Motu, but he must have regained it when he was made Physician to the Household. He practised medicine, surgery, and, it seems by his notes in the De Generatione, diseases of women especially.

The title of Medicus Regius, meaning Physician to either James or Charles or their Queens, was held by no less than 16 men besides Harvey. Five of them were knighted, which Harvey was not. Sir Matthew Lister was Physician to Henrietta Maria, and when she was confined at Exeter in 1644, he and Mayerne went down to see her. But the great man of the time was Sir Theodore Turquet de Mayerne. In 1644, the Queen, writing to him, signs herself "votre bien bonne maitresse et amie," and Charles writes "Mayerne, Pour l'amour de Dieu, allez trouver ma femme."

On May 19th, 1645, he was paid the greatest compliment that Parliament has ever, I suppose, paid to a medical man. The Lords sent down a message to the Commons:—

> "The Lords desire that the House of Commons would join with them in expressing their esteem of a man whose extraordinary abilities would make him welcome in any part of Christendom: and as he is singular for his knowledge in his profession, so he may be singular in being by the favour of the House exempted from all payments which others are subject unto: it being but a continuation of that favour which he hath enjoyed for about 30 years without interruption."

The House of Commons agreed by 69 to 66.

OTHER SCIENCES.

The other sciences in Harvey's time were as little advanced as medicine. Chemistry was first studied seriously by Robert Boyle at the end of Harvey's life; physics had produced in 1600 the book of Gilbert, President of the College that year, on the Lodestone, a work of the first class of which parts are still standard. Napier had in 1614 invented logarithms. But the science which advanced most rapidly in Harvey's life was astronomy. Galileo was lecturing in Padua when he was there, Kepler died in 1630, and in 1637 a poor Lancashire clergyman named Horrocks with borrowed lenses observed for the first time the transit of Venus. It has been questioned whether Harvey attended Galileo's lectures. As Galileo drew enormous audiences it is almost certain that he did, but if so they seem to have made but small impression for his references to astronomy are merely to disparage its methods in comparison with the direct observation of anatomy.

There was, however, a good deal of amateur experiment and invention. Prince Rupert dabbled in chemistry, the Marquis of Worcester had set up at Raglan Castle hydraulic machinery which frightened the Parliamentary Commissioners out of their wits, and Petty patented his first invention in 1647. There was also a small group of men who sought relief from the troubles of the times in the study of natural philosophy. They met in London up to 1648 and latterly at Gresham College, which Hobbes says had absorbed the natural sciences from the universities, but as in that year it was used as a barracks they transferred their meetings to Oxford. Harvey was at Oxford when they met in London, and when they met at Oxford he had already left it. He never therefore formed one of the group, which was the nucleus of the Royal Society. Even so it is rather curious that Sprat's "History of the Royal Society" (published in 1667) makes no mention of Harvey as a precursor.

In striking contrast to the infantile condition of science was the maturity of art and literature.

THE ARTS.

In Harvey's time there was a great enthusiasm for painting and sculpture. Charles is said to have had the finest collection of pictures in Europe. Arundel was second only to the King. Denbigh also collected. But they were not alone. Buckingham and many others were collectors, and it was not confined to court circles. Colonel Hutchinson was a good judge and Mrs. Cromwell had a collection of portraits. There was no native school, though Dobson painted good portraits, but the seventeenth century was the age of the Dutch, Flemish, and Spanish schools, and collectors can seldom have had such chances. Vandyck lived for several years at different times in England and Rubens was sent over as ambassador.

Harvey was undoubtedly interested in painting, for Arundel gave him a commission to buy for the King in Italy, and when he escaped from quarantine he travelled to Florence and Rome under the guidance of Mr. Petty, a clergyman who collected in Italy and the Near East for Arundel. By his introductions he was very courteously treated by the Grand Duke of Tuscany, who was a scientific man, and by Cardinal

Barberini at Rome, but he was an amateur at buying and failed to get anything of value.

Another art that was universally cultivated then was music. From 1590 to 1640 English music was at its zenith. The Puritans stopped ecclesiastical music, but rather because it was favoured by the bishops than that they themselves objected to it. There was a good deal of destruction of organs and church instruments at the hands of the soldiers. But it was not widespread, and the Puritans themselves sang psalms. Secular music was never thought wrong by anyone, and it is quite untrue to say that the Puritans set their faces against it. Bunyan, Milton, Cromwell, and Colonel Hutchinson were all devoted to music, and Colonel Hutchinson to dancing also, yet no one was a stricter Puritan than he. Cromwell was the first man who provided a Court Concert as an entertainment for his friends. His Ambassador to Sweden, Whitelock, took musicians with him, and was himself a performer. In fact in those days it was a regular part of a gentleman's education, whatever his religion or his politics. One of the best composers of song music was Henry Lawes, to whom Milton writes an Ode, and he, in 1655, published a collection of Ayres, dedicated to Lady Dering, who composed three of the pieces in it. This is Daniel Harvey's daughter. Mrs. Hutchinson also composed. In the ten years 1650 to 1659 there are 34 publications of musical works.

But of course nothing equals in significance the fact that Harvey's life was practically conterminous with what we term Elizabethan literature, the greatest outburst of literary genius that the world has ever seen. The first three books of the "Faerie Queene" were published when Harvey was 11 years old, and Herrick's "Hesperides" in 1648, when he was 70, and between those dates lie all the greatest names in English literature.

I have wondered whether, in their early married life, Dr. and Mrs. Harvey took a boat across to Bankside, where Shakespeare's plays were being given at the Globe up to 1613. I have wondered, too, what Harvey thought of the "Religio Medici" which was circulating in MS. in 1636 and what he would have said to Browne if they had met. We know Browne's opinion of the "De Motu." In recommending it to his son Edward and another doctor called Power, he speaks of it as a greater discovery than that of Columbus.

Harvey quotes Virgil and Terence, but he gives no sign that he had ever read or heard of the great writers of his own day. But a writer on scientific subjects can hardly be expected to quote contemporary poetry. Tennyson's "In Memoriam" shows that Tennyson had read Darwin, but I do not remember that Darwin quotes Tennyson. It does not seem a habit of great men of science to quote poetry. We need not, therefore, suppose that Harvey's silence means that he was without knowledge of the wonderful art around him; on the contrary, we know that he mixed with men who held it in the highest honour. Charles kept a Shakespeare in his bedroom. But in the first half of the seventeenth century the interest of most men was turned not to literature, nor to painting, nor to science, but to two subjects, which of all others are the most inimical to the cultivation of science or of art, politics and religion.

POLITICS.

The chief social change in the sixteenth century was the rise in wealth and influence of the upper middle class, including the squires in the country and the merchants in the towns. Both were of the same stock, for younger sons went into trade, and merchants who succeeded bought land. Some families combined both. The Barnardistons were an old Suffolk family in 1600, and are there still. The head of the family in Charles's reign, Sir Nathaniel, was Governor of the Levant Company and a prominent Member of the Long Parliament. The squires profited by the ruin, in the Wars of the Roses, of the old nobility whose estates they bought, and also by grants and cheap leases of the Abbey lands under Henry VIII.; both they and the merchants, by the great increase of the cloth trade which began under Edward IV., increased under Henry VII., and continued with fluctuations throughout the century. It led to a great demand for sheep pasture, and this in turn to a fourfold rise in rents, as related by Latimer, and to a large reduction of arable land to pasture, as described in the Utopia. But this again threw so many labourers out of work that Elizabeth was obliged to pass a new poor-law to save them from starvation. The House of Commons was practically filled by the squires, the merchants, and the lawyers who sprang from both.

The Tudors, the ablest and the only native dynasty we have ever had, knew the House of Commons thoroughly, and except in matters of religion, managed them with great tact. But Elizabeth, with all her prestige and popularity, so clearly recognised their reluctance to grant money that she practised the most sordid parsimony, suffered her great public servants to die in poverty, and poisoned the soldiers and sailors who saved England with bad victuals sooner than ask for supplies.

James, coming as a foreigner from a country where the middle classes had no power, and ignorant of our great political struggles in past centuries, was as entirely unable to recognise the position of the Commons as he was personally incapable of dealing with them. His silly profusion brought him rapidly to poverty, and he presented the ironic spectacle of a King blustering about his sovereign power and in the same breath begging for money to pay his tradesmen. No wonder that the Commons lost their loyalty to the Crown. In 1621 James tore out of the Commons' Journals the dignified declaration in which they stated their rights and liberties, and in 1625 he died at the end of the negotiations for the Spanish match, an enterprise begun with the usual Stuart disregard of the national feeling, pursued with the usual Stuart duplicity, and ending in the usual Stuart ill-success.

For Charles there was less excuse. He had taken a prominent part in politics for some years before his accession and had abundant opportunity to learn. But if a man cannot learn by experience, wherewithal can he be instructed? He was, in his first years, dominated by his evil genius, Buckingham, and though the Commons undoubtedly treated him very badly at that time, yet surely no man could have treated them with less tact than Charles. A Venetian wrote of him: "This King is so framed by Constitution that he can never oblige any man by word or deed." When he finally decided to govern without Parliament, his arbitrary measures, if not against the letter of the law—and it must be remembered that he had the warrant of most of his judges for what he did—were so completely against the spirit both of the Constitution and of the Petition of Right, which he had recently signed, that he irretrievably alienated both Parliament and the country.

Moreover, both parties, the King and the Commons, were equally justified in distrusting each other. If the Commons had good cause to distrust Charles, and they certainly had, Charles had equally good grounds to distrust them. Faction ran high; what was voted on Monday was rescinded on Tuesday, and at the end the majority who wished to continue negotiations were expelled from the House by the Minority and the Army.

In my young days small boys were occasionally puzzled by the question "What happens when an irresistible force comes against an immovable post?" It not inaptly represents the positions of the Parliament and the King.

RELIGION.

But the desire for political liberty had small influence compared to the violence of religious fanaticism. Religious grievances were invariably placed first in all the transactions of the House of

Commons. Henry VIII., to gratify his own passions, had led the nation to revolt from the Pope. But beyond a change of supremacy the religious practice of England was, for many years, little altered. Gradually, however, and more rapidly after the Marian persecution, Calvinism spread over the whole of England and Scotland. The City of London and the universities were its chief strongholds.

It is difficult for us to understand its appeal. Probably few Fellows of the College have laboured under the conviction of original sin and the certainty of damnation which clouded Cromwell's early manhood, or have experienced the assurance of saving grace which was his comfort and support in later life. But we can imagine how men, accustomed to the lax religion of the time, administered by an ignorant and careless clergy, for such they were, must have been affected by the greatest Revival that has ever taken place, to which Wesley and the Salvation Army are but ripples on a pond to a storm in the ocean, and what, to men living under the formalism of Rome, must have seemed the splendour of Calvin's great announcement that the creature could commune with the Creator, that the individual soul could approach the Divinity, that there was no barrier between God and man. Men's minds are naturally fascinated by horrors. Gloomy creeds have created the fiercest enthusiasm, and the Independents, the logical sons of Calvin, though he would have been the first to disown them, formed the most remarkable army that England has ever raised.

But if we find it hard to understand the acceptance of Calvinism, still harder is it to comprehend a society in which toleration was not only not approved, but was even abhorred as treachery to God. The Puritans were mocked as saints, but they spoke of themselves by the same term, and it was not always undeserved. Some of them were as truly saints as any that religion ever had. But even such men hated their opponents with a violence we can hardly believe, and had no thought of allowing them any kind of toleration. Calvinist, Arminian, Anglican, Independent and Papist, each was convinced that his own opinion was the true, and each was determined that it should be enforced on every man, woman, and child in the country.

Posterity has undoubtedly approved the political aims of the Long Parliament and looks upon it rightly as the preserver of English liberty. We are, therefore, the more astonished to observe the complete dearth of constructive political ability which marks their ranks. They pulled down everything; they built nothing. The Calvinists destroyed the Church, the Independents destroyed the Commons, the Lords and the Monarchy, and they themselves, when they turned out the Rump and set up the Protectorate, were attacked by the Republicans and Fifth Monarchy men, who plotted the assassination of Cromwell.

Compare what Cromwell, honestly anxious to restore good Government, could do for England in the years of his power, with the complete system of administration, religious, educational, judicial, municipal and financial, which Napoleon established between 1800 and 1811; or if you like a modern instance, with the system of government established in Italy since the war. It may be that when Mussolini dies the edifice will fall, but see what force and what creative imagination he has displayed.

The Government under the Commonwealth is, in England, a long series of failures, and in Ireland one of the greatest political crimes on record. Charles lost his cause, luckily for us. But in the personal struggle he was the victor. He had more foresight than any of them. He always believed that the rebellion would break down and the monarchy be restored, if not in his time, then in his son's. Accordingly he resisted to the utmost, and by so doing forced his foes into such violent and illegal courses as completely lost them the sympathy of the nation. After his execution they never dared to summon a freely elected [illegible] it, they were driven to acts of great [illegible] despotism, and when the strong hand of Cromwell was removed, they perished by their own dissensions and by the universal detestation that their tyranny had evoked.

But if posterity has approved the political aims of the Long Parliament, it has condemned their religious purposes no less emphatically. The views which Laud held about the Anglican Church are those now held by its members, the clergy now are as Laud would have had them, and the services are such as Laud wished and would have aroused Elliot to fury. But these are small matters.

The great vice of the age was its intolerance, and the religious mania, for we can call it nothing else, which overran England between 1560 and 1660 like an epidemic, did not even, like bodily epidemics, leave a population behind it immune to its particular poison. Never was religious hatred more bitter than after the Restoration, and in its graver forms it persisted for over a century and a half. Catholic emancipation was not carried till 1829, Oxford and Cambridge were not thrown open till 1871, and mutual respect and goodwill between the Free and the Established Churches is a growth of the last 30 or 40 years.

It has been claimed that the Puritans preserved the family life of England from the corruption and the licentiousness of Court manners. Such statements assume, on the one hand, that the Court society of the day was something exceptional, and on the other that the manners of the capital were the manners of the country. Neither is true. The fashionable London society of that day, as of this, was composed of people in affluent circumstances, occupied chiefly with their own pleasures and their own selfish interests, with leisure and without, for the most part, serious occupation. Can you suppose that such a society could exist, have you ever known such a society to exist either in London or any other capital against which the accusation of vice and folly could not be brought? There was nothing exceptionally wicked in society then. There were some scandals—the Somerset and the Purbeck stories, for instance, there were drunkards and profligates, there were family quarrels—when Lady Hatton asked James to dinner he suggested it might be a good occasion to make up her quarrel with her second husband, Sir Edward Coke; she said if her husband came in at one door she would go out at the other. But in all these points was society then very different from the present, and could we not from the law reports parallel every one of them over and over again at the present day?

Charles himself was too uxorious, and at a time when old Lady Arundel and young Lady Derby, when the elder Lady Verney, whom her husband always called "Good Puss," and the younger Lady Verney, whom the whole family nicknamed "Mischief," when Mrs. Hutchinson and Lady Wandesford and Lady Fanshawe, and, above all, Dorothy Osborne, were alive, and when the stage was trodden by those exquisite types of English girlhood, whom we could match to-day, Portia, Rosalind, and Celia, Beatrice, Imogen, and Miranda—do you think that there can have been much amiss with the position of women?

It is said too that to the Puritans we owe that sturdiness which has kept and increased the liberty they won. Neither is this to be accepted. Lived there no brave men before Agamemnon? Did not the men of that day expressly proclaim themselves followers in their fathers' footsteps, guardians of what they had obtained by peril of their lives? The temper of a great nation is a thing too firmly set to change under every blast of new doctrine, and its history is the consequence of its character, not the cause of it.

The Puritans were the guardians of spiritual fervour at a season when religion had become cold and dead. Such seasons of decay occur from time to time, and the Puritans are neither the first nor the last of the Revivalists. Whenever need arises such men have a great part cast for them on the world's theatre, and none of us should criticise them.

so harshly as to refuse them their due praise. But we owe to them the loss of half the beauty of England. They destroyed the drama, they sold the finest collection of pictures in Europe, and even ordered the religious pictures to be burnt as superstitious, there is not a village church which does not bear the marks of their barbarous hands, and three several times it was proposed in Parliament to pull down the Cathedrals and sell the materials for what they would fetch.

But, after all, our interest is not to praise or blame the actors in this great tragedy. It is to consider what was Harvey's attitude to the great struggles, political and religious, that were taking place around him. And of this we obtain from himself no evidence whatever. He mentions the King and Queen two or three times in the "De Generatione," but without any word either of affection or regret, which indeed in 1651 it might not have been prudent to print. He mentions Parliament once, complaining that the mob had destroyed his collections, though he was attending the King with the permission, and even at the command, of Parliament. There remains only the message that he is said to have sent to Scarborough, who was an ardent royalist, "Leave thy gunning and come here and I will bring thee into practice." But that may be significant.

We may well believe that he would not approve either the folly and tyranny of Charles or the violence and malice of his foes. To Harvey the war must have seemed a vast catastrophe, for which both parties were alike responsible, from which little good was gained, and by which the progress of knowledge was irreparably hindered.

And for religion. No man of serious character then doubted the fundamental beliefs of Christianity, and Harvey was of a reverent mind. But we cannot fancy his sympathising either with Laud's formal discipline or with the brutal irreverence of the Puritans. Harvey's religious feelings, we may be sure, were too sincere and too deeply felt ever to be published to the world.

Addison once asked Garth of what religion he was. Garth replied, "Wise men all hold the same religion." "What is that?" said Addison, and Garth answered, "Wise men never tell."

A STUDY OF THE EFFECT OF RADIANT HEAT ON THE PRODUCTION OF ACTINIC ERYTHEMA.

BY F. MACKENZIE SHATTOCK, M.B. LOND.,
RESEARCH WORKER, ROYAL FREE HOSPITAL LIGHT DEPARTMENT;
AND
MARY D. WALLER, B.Sc.,
LECTURER IN PHYSICS, LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.

AN investigation into the effect of radiant heat on the production of actinic erythema was started in May, 1928, and was carried out at first in the actinotherapeutic department of the Royal Free Hospital and later, when laboratory conditions became essential, in the physics department of the London School of Medicine for Women.

The possible interaction of shorter and longer wave-lengths is of some practical and clinical importance. Infra-red radiations constitute a large proportion of the energy given out by all sources of ultra-violet light, the association of radiant heat with mercury-vapour light treatment has been advocated and incandescent filaments are used as resistance units in some types of mercury-vapour lamps. Moreover, it may be presumed that clinical differences in the therapeutic value of mercury-vapour and carbon arc lamps depend partly on different percentages of the various wave-lengths in these sources of ultra-violet energy.

No attempt has been made in this preliminary investigation to estimate the therapeutic value of combining long and short wave radiation. The effect of the rays on the production of actinic erythema was alone investigated. It was hoped that a study of the skin reaction might give some indication which would prove to be of clinical value.

The following references to the more important contributions on the subject indicate the divergent opinions held by various observers. Thedering,[1] in 1916, stated that, in the treatment of one patient, red and infra-red light immediately after an erythema dose of ultra-violet light diminished the intensity and duration of the cutaneous reaction. Benoit,[2] in 1923 and 1926, stated that the addition of infra-red to ultra-violet light diminishes the cutaneous reaction. Infra-red preceding ultra-violet irradiation will increase the reaction, and following it will produce a local clearing of the erythema. Peemoller[3] quotes a case where erythema was obtained after three minutes exposure to mercury-vapour light and radiant heat, and after four minutes to mercury vapour alone. He considers that all hyperæmia-producing skin irritation is capable of increasing the action of the erythema-producing ultra-violet rays. Stahl and Simsch[4] state that skin hyperæmia caused by the heat of a summer's day increases erythema and pigmentation; friction of the skin after a cold bath has the same result. Anæmia of the skin produced by a short cold bath decreases erythema and increases pigmentation. The same action is produced by a cool wind. This view is commonly found in German publications, where the reinforcing action of infra-red rays is generally taken for granted. Poch[5] insists on the antagonistic action of infra-red and ultra-violet radiation. He states that the addition of infra-red rays to ultra-violet light will necessitate a longer exposure for the production of an actinic erythema. *Dufestel*[6] *considers that in practical actinotherapy* the weak antagonistic action of infra-red rays can be neglected. Radiant heat in small doses increases the reaction, whereas radiant heat in larger doses, given for an hour to an hour and a half after mercury-vapour irradiation, decreases the reaction. Hill and Eidinow,[7] using a mercury-vapour lamp, obtained an erythema after ten minutes irradiation at ordinary room temperatures; this was intensified if the exposure was made in a hot room and reduced to almost nothing if made in a cold room at freezing temperature. They consider that cold retards, but cannot stop, the biological action of ultra-violet rays.

Fuller lists of references can be found in A. C. Guillaume's "Les Radiations Lumineuses," Paris, 1927, and Dufestel's "Ultra-violets et chaleur radiante," but the above quotations may suffice *to show how various are the views of different* observers.

We consider that experiments with the data and precautions mentioned below are necessary for obtaining reliable results.

Experimental Details.

The aim of our experiments was to ascertain whether the addition of "radiant heat" rays had any appreciable effect, either synergic or antagonistic, on the production of actinic erythema, and whether, if any such effect be noted, it can be attributed to some "physiological" action or "physical" cause.

The lamps used as sources of ultra-violet radiation were: a Finsen-Reyn carbon arc (15–18 A, 70–80 V) lamp, a vertical carbon arc (15–18 A, 55–60 V), a smaller vertical carbon arc (7 A, 35–40 V), a Kromayer mercury-vapour lamp (3 A type), and a mercury-vapour lamp of the Hanovia type, without reflector (2 A, 145 V). For convenience in the text we use the term "ultra-violet" light for the radiation given out by these lamps, recognising that visible and infra-red rays are also present.

The source of "infra-red" or "heat" or "long-wave" radiation used was the resistance element from a "bowl-type" electric heater at red heat. The radiation given out is mainly in the infra-red region (maximum energy in the third octave of the infra-red, about 36,000 A.U.).

The filters used were two cells, 1 and 4 cm. deep respectively, with flat quartz faces. Through these cells fresh distilled water circulated; water absorbs rays beyond the first octave of the infra-red, thus cutting off a great portion of the longer rays.

We considered it necessary to make exposures on a part of the body not usually exposed to light—the thigh or abdomen—and each reaction was tested against a control, made on a corresponding symmetrical area of skin on the other side of the body. Re-exposure of the same areas during later experiments was carefully avoided.

Statements comparing erythema are usually based on the differences observed on the following day—i.e., about 24 hours after exposure. From previous clinical observations the impression had already been gained that two erythemas of varying depth may, after 24 hours, be indistinguishable; that the rate of fading of symmetrical parts does not always run a parallel course, and that the illumination (natural or artificial) in which the erythema is viewed plays a rôle in the appreciation of its intensity. Other accidental factors, such as baths, friction from clothes, and warming or cooling also make the comparison of fading erythemas difficult, as the effect on two observed parts is not always identical. Hence frequent observations during the first few hours were considered essential. It is also desirable when comparing the relative intensity of two reactions to observe them when they are at their maximum. With the depths of erythema obtained, pigment formation was not sufficiently marked to be used for purposes of comparison and is therefore not recorded, though it was observed in some cases. Differences in colour of the pigment of the heated and non-heated areas were noticed, the latter being greyer and less brown.

We have recorded experiments made on medical students and ourselves, noting the latent period (time elapsing before the appearance of visible erythema), rate of increase of erythema, maximum reaction (colour and depth), duration and rate of fading. Rigid clamped screens of asbestos, with diaphragms for exposure of the skin, were employed. Two screens separated by about 1 cm. of air were used, as a single screen was liable to conduct heat through to the skin. It is of great importance to keep the distances constant, in view of the rapid falling-off of light intensity with distance. Care was taken that the light should fall normally on the skin and that there should be no undue pressure from the screen.

Constancy of Response to Equal Irradiation of Symmetrical Areas of Skin.

1. Six experiments (12 exposures) were made on six subjects by exposing corresponding areas for three minutes to a mercury-vapour lamp (2 A, 145 V), 22 in. distant; the light was filtered through a distilled water screen.

2. Six similar experiments (12 exposures) were made with an addition of infra-red radiation to the filtered mercury-vapour light. (The source of infra-red radiation was placed at an angle between the skin and the quartz cell, which was fixed in an asbestos screen.) Identical depths of erythema were obtained in corresponding couples of exposures in each of the 12 experiments, though minor differences in the rate of fading were noticed.

We wish to emphasise the necessity and reliability, as shown by these experiments, of this method of observation—i.e., of using corresponding areas on the two sides of the body.

Effect of Varying Exposures on the Depth of Erythema.

A series of six experiments on five subjects was made to determine what percentage increase of exposure will produce a perceptible difference in the depth of erythema. Exposures to a mercury-vapour lamp (1·75 A, 150 V) at 23 in., for 5, 4, 3, and 2 minutes respectively were given. The latent periods increased with decreasing exposures—e.g., in one experiment from 2 to 3½ hours, in another from 4½ to 9¼ hours. The erythemas observed showed that at least 20 to 30 per cent. increase of exposure is necessary to produce a perceptible difference of erythema, and that a careful observation of the latent periods under identical conditions of exposure is a more accurate indicator of the length of exposure than the observation of the depth of actinic erythema.

Experiments with Mercury-vapour Light to which Infra-red Rays are Added.

1. A preliminary series of ten separate experiments on five subjects was made, using a Kromayer lamp as source of filtered ultra-violet light, and the radiator described above as a source of infra-red rays. Small corresponding areas were exposed to the ultra-violet radiation, and to the ultra-violet and infra-red radiation respectively, the distances and exposures being kept constant in any one experiment. With distances from the lamp of from 10½ to 12 in., exposures of from three to five minutes, and heating to the limit of toleration (radiator 6–8 in. distant) the actinic erythema was diminished by the addition of the infra-red radiation in all the experiments, and (where a conclusion could be drawn) the latent period was definitely delayed on the side exposed to infra-red rays. The maximum difference was found in an experiment in which the latent periods were five hours and eight and a half hours respectively, while in two cases faint erythemas, with latent periods of six and seven hours respectively on the one side, were suppressed on the side exposed to infra-red rays.

2. Five experiments were made in which the tissues on one side were cooled by a draught of cold air (driven by an electric motor) during irradiation with the Kromayer lamp. The other side received a similar irradiation with the addition of infra-red radiation in two experiments, and a hot air draught in two other experiments, while in the fifth experiment the Kromayer light only was used. The erythemas were greater and the latent times less on the cooled side in four cases, while in the one case (cf. hot *v.* cold draught) no detectable differences were seen.

3. In the two series of six experiments each, devised to investigate the constancy of response of symmetrical areas, it was noticed that in the experiments in which filtered mercury-vapour light alone was used bigger reactions were obtained with shorter latent periods than in the experiments in which infra-red radiation was added to the filtered mercury-vapour light. The exposures in all 12 observations were three minutes and the distance from the lamp 22 in., so that the results were comparable.

4. Six experiments were made using a mercury-vapour lamp of the Hanovia type (without a reflector) and a water filter (depth 4 cm.), and on one side adding infra-red radiation. The addition of heat diminished the erythema in three cases, while no detectable differences were observed in three cases. In four cases the latent periods were increased, while in the other two cases they were approximately equal.

A summary of the experiments is given below.

Series.	No. of expts.	Erythema.		Latent periods.	
		Diminished by heat.	Visually equal.	Increased.	Decreased.
1.	10	10	0	6	0
2.	5	4	1	4	0
3.	6	3	3	6	0
4.	6	3	3	4	0
Total ..	27	20	7	20	0

In no case was the erythema increased by the addition of infra-red rays, and the visually equal erythemas are neutral evidence, since quite considerable differences of exposure are necessary to give visual differences in the depth of the erythema. The latent periods observed varied from about one to ten hours in different experiments; in no case were these diminished by the radiant heat. A difference of colour was always noted between two areas, one of which had been heated by the addition of infra-red rays or by conduction. The addition of heat causes a scarlet or vermilion erythema as compared with the more crimson or carmine colour of the usual mercury-vapour erythema. The same differences in colour were observed when comparing the actinic erythema following carbon arc light irradiation with that following irradiation with the same light filtered through water.

Experiments with Water-filtered Carbon Arc Light.

In this series a carbon arc was used because of the large amount of heat which it emits. Any small fluctuations of light intensity due to the flickering of the arc are immaterial when the two areas are irradiated simultaneously. Comparative observations of the erythema produced by the unfiltered and filtered rays were made in three ways.

1. Exposures to the Finsen-Reyn lamp through the quartz applicator empty, and subsequently through the quartz applicator filled with distilled water. Four experiments (one subject) were made. On account of the fluctuations of light intensity, experiments of this type are of little value and the experimental results were variable and contradictory.

2. Exposures of a larger area of skin, part of which only was covered with the quartz cell filled with distilled water. Three experiments were made, but they are of doubtful value, for the diminution of erythema observed is probably due, as was shown by photography, to a diminution of light after passage through the cell. Two similar experiments using a mercury-vapour arc gave similar actinic and photographic results.

Experiments of this type are quoted by some investigators as proving that an increased erythema is produced by screening through water. In our observations the screened side gave consistently smaller reactions. These experiments differ from those described in the other sections in that the control area does not receive the same, but a larger dose of ultra-violet light. Some of the loss of light was thought to be due to reflection at the surface of the cell.

3. Exposures through a circular quartz container, half filled with distilled water, so that the lower half only of the exposed skin received filtered light. Fourteen experiments on two subjects were made. Here again difficulties were encountered, sometimes due to the formation of water vapour in the upper part of the cell, a difficulty which was overcome by adjusting a stream of distilled water through the lower half of the cell from a Marriotte's bottle. Increased erythema in the lower half of the field was obtained in 5 of the 14 experiments; the other 9 showed equality. The lower field was noticed to be more brightly illuminated; the matter was investigated photographically by substituting a piece of Seltona P.O.P. paper for the skin, and exposing it to the radiation. Total reflection at the surface of the water actually increased the illumination in the lower half.

We have described this method carefully because erroneous conclusions have been based on experiments of this apparently accurate type. We wish to emphasise the difficulties inherent in the use of filters and to compare the inconclusive results obtained in the experiments described in this section with those in which heat is added during, before, or after the exposures to ultra-violet light.

P.O.P. paper was found to be a convenient method for comparing varying amounts of radiation from any one given U.V. lamp. From 5 per cent. to 10 per cent. (according to the depth of colour) increase of exposure to a given source of light is detectable—i.e., the paper is about four times more sensitive to variations in length of exposure than actinic erythema. Screening the paper with glass (absorption to 3300 A.U.) almost completely prevents darkening of the paper with the same lengths of exposure. The paper provides, therefore, a simple and sufficiently accurate method of examining the filters used in experiments of this type. Examination with a Beck ultra-violet spectroscope was a further check on the filters.

Effect of Heat following or preceding Irradiation with a Mercury-vapour Lamp.

These experiments were undertaken to determine whether heat, either in the form of "long-wave" radiation or from a hot water bottle applied to the skin, affects the erythema produced by the unscreened light of a mercury-vapour lamp, when the heat (1) follows, (2) precedes the ultra-violet radiation.

Sixteen experiments were performed on five subjects, placed 33 in. from the lamp. The current and voltage in any particular experiment were kept constant. The exposures given were three or four minutes, these being sufficient to give actinic erythemas in two to five hours, lasting from one to several days. Immediately before or immediately after irradiation the skin was heated from five to ten minutes by radiant heat or by a large corked test-tube of hot water, until a good diffuse primary erythema was obtained lasting half an hour or longer.

1. *Heat following irradiation.*—Eight separate experiments on three subjects were made; in four the skin was heated by means of the radiator and in four by means of the hot water test-tube. In six cases heat diminished the reaction; in one case heated by the radiator and in one case heated by the hot water no perceptible differences in the depths of erythema were seen. The usual differences in colour were observed. The latent periods were always increased. The duration of erythema was definitely shortened in five cases.

It was noticed that the part previously irradiated with mercury-vapour light was found to be very sensitive to heat. A painful sensation as compared with ordinary "warming" was experienced over this area when the tissues were warmed by either method.

2. *Heat preceding irradiation.*—Eight experiments on four subjects, in five of which the skin was heated by the radiator and in three of which the hot water bottle was employed, gave increased reaction on the heated side in six cases, while in two cases the reactions were apparently equal in depth. The usual differences of colour were noticed. There was slight delay (about 10 mins.) in three cases, otherwise the latent periods were not appreciably altered.

We conclude that when heat precedes irradiation there is a slight increase in actinic erythema. This effect is opposite and less than the diminished erythema which is obtained when heat either follows the irradiation or is applied simultaneously with the irradiation.

Conclusions.

1. Heating tissues by radiation or by conduction (radiator, hot water in vessel) after exposure to ultra-violet radiation diminishes—or suppresses—the actinic erythema and delays its appearance.

2. Heating of tissues by radiation of conduction before exposure to ultra-violet radiation increases the actinic erythema. The time of appearance of the actinic erythema is not appreciably influenced.

3. Heat (radiant heat or hot air draught) applied simultaneously with ultra-violet irradiation diminishes—or suppresses—the actinic erythema and delays its appearance.

4. Differences in colour as well as differences in depth of reaction are noticeable. The actinic erythema of the heated skin is more scarlet or vermilion (similar in colour to the primary erythema), as compared with the actinic erythema produced by the mercury-vapour or water-filtered carbon arc light, which is more crimson or carmine.

5. Differences of 20 to 30 per cent. of exposure to ultra-violet light are necessary to produce visual differences in the erythema. Smaller percentage differences of exposure to a given source of radiation will give appreciable differences in the latent period—i.e., the time elapsing before the appearance of erythema.

6. The diminution of actinic erythema by heating the tissues, either with radiant heat or by conduction, during ultra-violet irradiation, suggests a "physiological" rather than a "physical" cause for the diminution observed. The fact that at least equally satisfactory diminution of erythema can be obtained by heating after irradiation with ultra-violet light cannot be explained by physical interference or antagonism of the rays.

The observed action of ultra-violet light on the sensitiveness of the skin to thermal stimulation appears to be immediate and requires further investigation. It is suggested tentatively that this action may be a factor in determining the degree of actinic erythema in cases heated simultaneously or after ultra-violet irradiation.

Our thanks are due to Dr. C. B. Heald for the facilities given us in the Light Department of the Royal Free Hospital, and we are grateful to the Waller Memorial Research Fund Trust for a grant in connexion with the expenses of the research.

OBSERVATIONS ON VACCINATION.*

BY S. P. BEDSON, M.D., M.Sc. DURH.,
SENIOR FREEDOM RESEARCH FELLOW, LONDON HOSPITAL.

ALTHOUGH the method of prophylactic immunisation against small-pox has undergone no fundamental change since Jenner's time, certain modifications and improvements have been made in it. Arm-to-arm vaccination has been abandoned for obvious reasons. Vaccine lymph is now produced in large quantities and under carefully controlled conditions. The calf is the animal most generally employed for this purpose, but since the virus of cow-pox tends to behave irregularly after prolonged passage in this animal, passage through other animals, such as the rabbit, has become necessary from time to time to rejuvenate the virus. Again, when fresh seed lymphs are required one now has recourse to cases of small-pox. The virus of small-pox, when established either directly in calves or after preliminary passage through monkeys or rabbits, acquires the characters of cow-pox; in fact, the two viruses are immunologically identical, and differ only in their species adaptation.

The Jennerian method of vaccination has always had its opponents. These have steadily increased in number, and it is claimed by the antivaccinators that this method of preventive inoculation is attended not infrequently by untoward consequences. These claims have been very largely discounted by the medical profession, and rightly so. Opposition has come almost entirely from those ill-qualified to pronounce on the matter, and it has been felt that the claims were the outcome of too free a use of that faulty line of reasoning, *post hoc ergo propter hoc.*

Encephalitis.

Of late years, however, a complication of vaccination has made its appearance which, though of rare occurrence, is disquieting because of its high rate of mortality. I refer, of course, to post-vaccinal encephalitis. The onset is abrupt, some 9 to 12 days after vaccination, with headache, vomiting, and drowsiness. The patient usually passes into coma, and the other signs present vary with the portion of the central nervous system involved. About half the cases end fatally; those that recover do so completely without residual symptoms. This form of encephalomyelitis closely resembles those cases which occur rarely in the course of acute infectious diseases, such as measles, small-pox, chicken-pox, and mumps, and this resemblance extends to the essential histological lesion which has been shown to be a perivascular demyelination.

Post-vaccinal encephalitis was first recognised in 1912, when a case occurred at the London Hospital. It reappeared in 1922 when, again at the London Hospital, four cases were recognised and submitted to a detailed investigation. Between 1922 and 1927, 93 cases have occurred in this country, representing an incidence of 1 in 48,823 persons vaccinated; 62, or 66·6 per cent., of these cases occurred in patients between the ages of 5 and 14 years. Apparently the unvaccinated infant and persons submitting to revaccination are not susceptible. This statement requires some slight qualification since Turnbull has described one case in an infant under three months. However, this appears to be the only case of the kind on record, and one may therefore conclude that the susceptible individual is the one submitting to primary vaccination at any age after infancy, but more particularly between the ages of 5 and 14 years. In this connexion the figures for post-vaccinal encephalitis in Holland are of interest. In that country primary vaccination has been very largely practised at school age, and for the period 1922–27, 123 cases occurred out of 495,431 vaccinated, or 1 in 4028. This gives us a clearer conception of the risk attendant on primary vaccination in those other than infants.

The ætiology of post-vaccinal encephalitis remains obscure. There are three hypotheses current. The condition may be due to the vaccinia virus; infection with the vaccinia virus may light up a dormant neurotropic virus which the patient was harbouring; or, as has been most recently claimed, the condition may be a toxic one. The last conception seems to me difficult to accept. Occasional cases of post-vaccinal encephalomyelitis have taken the form of a transverse myelitis without other involvement of the central nervous system, and these cases are not readily explained on a toxic basis. The probability is, therefore, that we are dealing with a condition produced either directly by the vaccinia virus or indirectly through the activation of an unknown latent virus by the vaccinia virus. Whichever of the two views may be correct, it appears to me necessary for the vaccinia virus to invade the body generally, and the central nervous system in particular, for post-vaccinal encephalitis to occur.

The Practitioner and Vaccination.

The question of practical importance is: What is to be the attitude of the medical practitioner towards vaccination? There are those whose reply is: Continue vaccinating as before. It is inconceivable to my mind that any one should adopt such an attitude. Were we dealing with protection against the risk of virulent small-pox there might be some excuse for this attitude. Even so, it would be a confession of ineptitude on our part. But the type of small-pox in this country at the present time is extremely mild and rarely fatal, so that to continue vaccinating as before would be to ask the individual to submit to a prophylactic measure whose risk of death equalled that of the disease against which he was being protected.

Obviously something must be done.

Diluted Lymph.

It is clear from animal experiments with vaccinia virus that the degree of invasion varies directly with the dose inoculated. It occurred to me therefore that the risk of encephalitis should be lessened if a smaller inoculum were used, and during the last three years diluted calf lymph has been in use at the London Hospital, though only in the last six months has it been used at all excessively. The dilutions have varied from 10- to 50-fold, the diluent employed being an M/50 phosphate solution, pH 7·6, though saline or sterile water could be used. The diluted lymph is used within 24, or at most 48 hours, after dilution, and it has been the practice to vaccinate in two places, using a crucial incision of ⅜ inch diameter. The Vaccination Committee of the Ministry of Health obviously had the same idea, for they recommended one insertion of the undiluted lymph by means of a ½ inch linear incision in place of the usual cross hatching.

It is not claimed that the use of diluted lymph is the solution of the problem with which we are faced. It is, however, reasonable to suppose that it considerably reduces the risk of post-vaccinal encephalitis. It certainly gives much more satisfactory takes, and

out of some 700 patients so vaccinated no excessive reactions have been observed. The number of primary vaccinations at a susceptible age has been very small, so that, of course, it is impossible to draw any conclusions as to efficacy of this method as a means of avoiding post-vaccinal encephalitis. However, no such cases have occurred. The ideal to be aimed at is a perfectly safe method of immunisation against small-pox, and it is our hope that such a method will be evolved. It has been shown that if the virus of foot-and-mouth disease is inactivated by means of formalin in low concentration it still retains its antigenic properties, and this method has been employed in the preparation of vaccines for distemper and yellow fever. Work is in progress here to find out whether some such method could not be applied to the vaccinia virus.

These experiments, which are being carried out by my colleague, Dr. J. Bland, are as yet in their infancy, and it is impossible to say what the outcome of them will be. In the meantime, however, I would make the following suggestions: (1) When vaccinating infants, or performing revaccination, use lymph diluted 1 in 10, making one or two insertions with a crucial incision (*no cross hatching*), or vaccinate as the Ministry of Health have recommended, making one insertion with a single linear incision, using undiluted lymph. (2) When called upon to perform primary vaccination in any person other than an infant, find out first of all if it is absolutely necessary to vaccinate. The only condition rendering vaccination necessary in such a case would be the risk of exposure to *virulent* small-pox. If you *have* to vaccinate a susceptible individual, then do so with lymph diluted 1 in 50, making one insertion with crucial incision.

THE MEDICO-LEGAL SIGNIFICANCE OF BLOOD GROUPS.

By Dr. F. SCHIFF,

DIRECTOR, BACTERIOLOGICAL DEPARTMENT, MUNICIPAL HOSPITAL, FRIEDRICHSHAIN, BERLIN.

THE establishment of paternity by application of the rules governing the inheritance of the blood groups is now receiving a great deal of attention. The results obtained with this method were recently reviewed in a leading article in THE LANCET (1928, ii., 711). *I propose to make some observations on this article.*

What does the Blood Test Establish?

A case of doubtful paternity may be chosen in order to demonstrate the application of the method. Here the blood groups of the mother and the child would be established as well as that of the alleged father (possibly those of several men). The results obtained are then considered as to whether or not they are consistent with the rules governing the transmission of blood groups from parents to offspring as established by von Dungern and Hirszfeld (1911) and by Bernstein (1924). According to whether this conformity has been established or not the answer would be: (1) the man examined may be the father; (2) the man examined cannot be the father.

It is evident that the "blood test," far from being a method for diagnosing paternity, is, in certain cases, capable of merely excluding an alleged paternity. The method should, therefore, correctly be called "a test for the exclusion of paternity." The exclusion, of course, of a man who had been denounced unjustly can be established in one out of six or seven cases only.[1] This is due to the small number of blood groups existing. It often happens that a man who is not the father belongs to the same group as the actual father; in addition, there is a high incidence of cases showing such a disposition of the blood groups of mother and child as to preclude a priori any inference being drawn from the blood group of the father.

In the leading article above the position in Germany was referred to in detail; in that country the "blood test" has been systematically applied in forensic medicine since 1924.[2] It is very difficult for the outsider, and especially for the foreigner, to judge the position in Germany, owing to complicating juridical factors. It is understandable, therefore, if some misinterpretations have crept into the article in THE LANCET which I shall now try to correct.

Certain Misinterpretations.

The leading article in THE LANCET contains the following statement: "It has been laid down in Prussia that 'the impossibility of fatherhood cannot be legally regarded as being established absolutely (einwandfrei) by a blood examination.'" This quotation, it is true, reproduces the opinion of some judges, including one member of the Supreme Prussian Court of Appeal, but it does in no way represent a decree ruling out the acceptance of the results of the blood test as the basis of a verdict in the court. The sentence quoted represents only the individual opinion of a minority of jurists. Judge Leonhard is not the President of the Prussian Court of Appeal, as would be assumed according to the article in THE LANCET. He is President merely of one out of some 30 departments of this court, and his opinion has been contradicted not only by other departments of this court but also by numerous leading members of the bar and of the medical profession.[3] Leonhard[4] himself recently admitted that those who accept the blood test as a reliable means of evidence represent the dominant trend of opinion. Official decrees have been published in various States of the Reich[5] directing the attention of the courts to the new method of evidence and pointing out explicitly that it is capable, in suitable cases, of proving the impossibility of fatherhood. These decrees regulate at the same time the details of the procedure of a more administrative nature. Numerous verdicts of supreme courts of appeal have been published which have been based on the results of the blood examination.[6]

The leading article in THE LANCET contains the following quotation from an official statement made by the Supreme Medical Council of Austria: "In the majority of cases the results of blood examinations will not assist in the establishment of paternity." German lawyers and medical men, too, interpreted this statement, but mistakenly, as a criticism of the reliability of the method. To the expert, however, it appears simply as a banality, indicating the well-known fact mentioned above, that the method is capable of affording a useful result in a minority of cases only. The decisive point, however, is, what is the attitude adopted by the courts in those cases in which the constellation of blood groups contradicts the possibility of fatherhood? In THE LANCET paper it is assumed, but not correctly, that no provision whatever has been made with regard to these cases. The promulgation referred to, published in the *Official Gazette of the Austrian Administration of* Justice, Nov. 8th, 1927,[7] stated explicitly: "According to the various blood groups established in an individual case the result obtained is capable of proving the impossibility of fatherhood for a given man." In accordance with this decree in Austria numerous verdicts have been based exclusively or for the greater part on the evidence afforded by blood grouping. A number of these verdicts, including such passed by the Vienna Supreme Court of Justice, have been published as long ago as in 1927.[8]

Exact data showing the extent and scope of the blood test in Germany have become available through an inquiry made by the writer on behalf of a committee formed by the Reichsgesundheitsamt (see *Medizinische Welt*, August 24th, 1929). The fact was revealed, surprising even for those acquainted with German conditions, that more than 5000 medico-legal examinations of this kind have already been

OBSERVATIONS ON VACCINATION.*

BY S. P. BEDSON, M.D., M.SC. DURH.,
SENIOR FREEDOM RESEARCH FELLOW, LONDON HOSPITAL.

ALTHOUGH the method of prophylactic immunisation against small-pox has undergone no fundamental change since Jenner's time, certain modifications and improvements have been made in it. Arm-to-arm vaccination has been abandoned for obvious reasons. Vaccine lymph is now produced in large quantities and under carefully controlled conditions. The calf is the animal most generally employed for this purpose, but since the virus of cow-pox tends to behave irregularly after prolonged passage in this animal, passage through other animals, such as the rabbit, has become necessary from time to time to rejuvenate the virus. Again, when fresh seed lymphs are required one now has recourse to cases of small-pox. The virus of small-pox, when established either directly in calves or after preliminary passage through monkeys or rabbits, acquires the characters of cow-pox; in fact, the two viruses are immunologically identical, and differ only in their species adaptation.

The Jennerian method of vaccination has always had its opponents. These have steadily increased in number, and it is claimed by the antivaccinators that this method of preventive inoculation is attended not infrequently by untoward consequences. These claims have been very largely discounted by the medical profession, and rightly so. Opposition has come almost entirely from those ill-qualified to pronounce on the matter, and it has been felt that the claims were the outcome of too free a use of that faulty line of reasoning, *post hoc ergo propter hoc.*

Encephalitis.

Of late years, however, a complication of vaccination has made its appearance which, though of rare occurrence, is disquieting because of its high rate of mortality. I refer, of course, to post-vaccinal encephalitis. The onset is abrupt, some 9 to 12 days after vaccination, with headache, vomiting, and drowsiness. The patient usually passes into coma, and the other signs present vary with the portion of the central nervous system involved. About half the cases end fatally; those that recover do so completely without residual symptoms. This form of encephalomyelitis closely resembles those cases which occur rarely in the course of acute infectious diseases, such as measles, small-pox, chicken-pox, and mumps, and this resemblance extends to the essential histological lesion which has been shown to be a perivascular demyelination.

Post-vaccinal encephalitis was first recognised in 1912, when a case occurred at the London Hospital. It reappeared in 1922 when, again at the London Hospital, four cases were recognised and submitted to a detailed investigation. Between 1922 and 1927, 93 cases have occurred in this country, representing an incidence of 1 in 48,823 persons vaccinated; 62, or 66·6 per cent., of these cases occurred in patients between the ages of 5 and 14 years. Apparently the unvaccinated infant and persons submitting to revaccination are not susceptible. This statement requires some slight qualification since Turnbull has described one case in an infant under three months. However, this appears to be the only case of the kind on record, and one may therefore conclude that the susceptible individual is the one submitting to primary vaccination at any age after infancy, but more particularly between the ages of 5 and 14 years. In this connexion the figures for post-vaccinal encephalitis in Holland are of interest. In that country primary vaccination has been very largely practised at school age, and for the period 1922–27, 123 cases occurred out of 495,431 vaccinated, or 1 in 4028. This gives us a clearer conception of the risk attendant on primary vaccination in those other than infants.

The ætiology of post-vaccinal encephalitis remains obscure. There are three hypotheses current. The condition may be due to the vaccinia virus; infection with the vaccinia virus may light up a dormant neurotropic virus which the patient was harbouring; or, as has been most recently claimed, the condition may be a toxic one. The last conception seems to me difficult to accept. Occasional cases of post-vaccinal encephalomyelitis have taken the form of a transverse myelitis without other involvement of the central nervous system, and these cases are not readily explained on a toxic basis. The probability is, therefore, that we are dealing with a condition produced either directly by the vaccinia virus or indirectly through the activation of an unknown latent virus by the vaccinia virus. Whichever of the two views may be correct, it appears to me necessary for the vaccinia virus to invade the body generally, and the central nervous system in particular, for post-vaccinal encephalitis to occur.

The Practitioner and Vaccination.

The question of practical importance is: What is to be the attitude of the medical practitioner towards vaccination? There are those whose reply is: Continue vaccinating as before. It is inconceivable to my mind that any one should adopt such an attitude. Were we dealing with protection against the risk of virulent small-pox there might be some excuse for this attitude. Even so, it would be a confession of ineptitude on our part. But the type of small-pox in this country at the present time is extremely mild and rarely fatal, so that to continue vaccinating as before would be to ask the individual to submit to a prophylactic measure whose risk of death equalled that of the disease against which he was being protected.

Obviously something must be done.

Diluted Lymph.

It is clear from animal experiments with vaccinia virus that the degree of invasion varies directly with the dose inoculated. It occurred to me therefore that the risk of encephalitis should be lessened if a smaller inoculum were used, and during the last three years diluted calf lymph has been in use at the London Hospital, though only in the last six months has it been used at all excessively. The dilutions have varied from 10- to 50-fold, the diluent employed being an M/50 phosphate solution, pH 7·6, though saline or sterile water could be used. The diluted lymph is used within 24, or at most 48 hours, after dilution, and it has been the practice to vaccinate in two places, using a crucial incision of ⅜ inch diameter. The Vaccination Committee of the Ministry of Health obviously had the same idea, for they recommended one insertion of the undiluted lymph by means of a ½ inch linear incision in place of the usual cross hatching.

It is not claimed that the use of diluted lymph is the solution of the problem with which we are faced. It is, however, reasonable to suppose that it considerably reduces the risk of post-vaccinal encephalitis. It certainly gives much more satisfactory takes, and

Clinical and Laboratory Notes.

A CASE OF ABDOMINAL AORTIC ANEURYSM,

WITH RUPTURE AND FORMATION OF FALSE ANEURYSM AND EXTENSIVE EROSION OF VERTEBRÆ.

BY JOHN K. RENNIE, M.D. GLASG.,
HON. PHYSICIAN, BRADFORD ROYAL INFIRMARY.

CASES of aneurysm of the abdominal aorta are comparatively common, and terminal rupture of the aneurysm is by no means rare. In the following case death occurred probably five months after the first rupture, and the history of the intervening period and the post-mortem findings seem worthy of record.

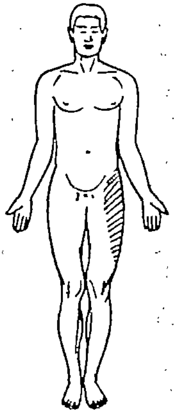
The patient, a storeman aged 43, was admitted to the Glasgow Royal Infirmary on Sept. 27th, 1927, complaining of pain in the abdomen. Four weeks before admission, while at work, he had been seized with an attack of acute pain in the right side of the abdomen. The pain had been very severe, "doubling him up," and had lasted for about 20 minutes. He had continued at work, but during the next two weeks the pain had recurred at intervals, commencing in the left upper abdomen and shooting downwards and outwards toward the left flank. On Sept. 19th he was compelled to give up his work as the attacks were occurring more frequently—three or four in the day—and the pain now radiated downward to the outer side of the left thigh. He made no complaint save of pain. His work was very hard, involving heavy lifting. He had always been a heavy drinker. He had had dysentery in Salonica in 1917 and had been in hospital for six months; but apart from occasional attacks of "influenza" he had otherwise been very healthy.

He was a small well-built man of healthy appearance. The abdomen was slightly distended, the distension being most marked in the upper part and particularly on the right side below the costal margin. Palpation in this area revealed a mass below and easily separated from the liver, slightly tender, with a rounded lower margin, and distinctly pulsatile. The pulsation was both forcible and expansile. On auscultation the cardiac sounds were heard even more distinctly than over the præcordium, and there was a loud systolic murmur. The spleen could not be felt, but there was some tenderness in the left hypochondrium. There was some general rigidity of the whole abdomen but no ascites. Posteriorly there was considerable resistance to palpation in the left lumbar region and immediately below the ribs a pulsating swelling was apparent, involving the twelfth rib in its movement. In this area also the heart sounds were heard with great distinctness. The lower dorsal and upper lumbar vertebræ were almost fixed and the spine showed a slight general kyphosis. He complained of pain in the left iliac region radiating down the outer side of the thigh. In the area of distribution of the ilio-hypogastric and external cutaneous nerves there was an anæsthesia to touch and pain (Fig. 1). The epigastric and abdominal reflexes were absent. The knee-jerks and ankle-jerks were present and equal. The plantar reflexes were equal and flexor in type. All other reflexes, including the pupillary, were normal. Movement at the hip- and knee-joints was free and painless. The heart was normal in size and position. There was a short systolic murmur at the apex and over the sternum. The lungs were normal. The liver was slightly enlarged. The urine was normal. The Wassermann reaction was + + + positive.

Radiography of the spine on Oct. 17th showed a lack of definition in the left border of the eleventh and twelfth dorsal vertebræ, and a distinct shadow on each side of the ninth, tenth, eleventh, and twelfth dorsal vertebræ.

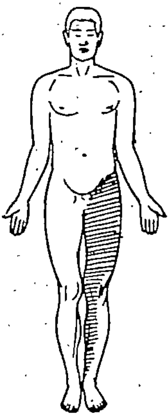
On Oct. 24th the patient complained of very severe pain in the left leg extending downwards from the buttock. He became very pale and collapsed with a weak and rapid pulse. Pulsation could still be felt in the upper abdomen and in the lumbar region, but the heart sounds were much more faintly heard. The entire left side of the abdomen became rigid but not tender. By the next morning he had rallied and appeared little changed, but the abdomen was now generally distended and rigid and there was a large area of dullness to percussion in the left flank. The left leg was held flexed at the hip and knee and any attempt to straighten the leg caused acute pain. No pulsation could now be detected in the left femoral artery. The right femoral artery was easily felt. On Oct. 26th and again on Oct. 31st similar attacks occurred, each of shorter duration, lasting about an hour. But whereas severe pain had preceded the collapse in the first attack, in the second and third attacks the collapse occurred without any pain whatsoever. From both attacks he recovered under stimulation. On Nov. 2nd a band of bluish discoloration was noted in the left flank, and the abdominal wall showed an area of induration and swelling clearly due to extravasated blood. The left knee-jerk could not now be elicited, but the left plantar reflex was present and flexor. There was complete anæsthesia over the front of the left thigh and the muscles of the thigh and leg were considerably atrophied. Gradually the discoloration disappeared and the indurated area in the abdominal wall became smaller, harder, and more defined above. Below it had spread downwards over Poupart's ligament, and the femoral artery could now be felt pulsating to its inner side. There was movement of the left foot and toes, but the leg could not be extended, probably on account of the pain, as the muscles could be felt to contract when the attempt was made.

FIG. 1.



Area of anæsthesia to touch and pain on Oct. 17th.

FIG. 2.



Area of anæsthesia to touch and pain on Nov. 29th.

On Nov. 20th œdema appeared in the left foot and leg. Bed-sores began to form over the back and legs. The general condition had greatly deteriorated and morphia became necessary on account of the discomfort. On Nov. 29th the mass on the left side had become very hard and localised. The sensory disturbance had increased in extent, involving the inner side of the left lower leg, and was clearly of root distribution (Fig. 2). The left plantar reflex remained active and flexor and vibration sense was unimpaired in the leg. On Dec. 6th incontinence of fæces commenced and on Dec. 10th the abdomen was much distended with free fluid. On Dec. 20th he had another attack of abdominal pain and collapse, from which he again recovered. Increasing œdema and weakness made accurate examination difficult, but the area of anæsthesia appeared unchanged. In spite of morphia, any attempt at movement at the left knee or hip still produced intense pain. The left knee-jerk remained absent, but the foot and toes could still be moved. On Jan. 5th an area of dullness was detected at the base of the left lung with diminished breath sounds. He became progressively weaker and died on Jan. 17th, 1928.

Post-mortem Report.

The valves of the heart appeared normal except for slight sclerosis in the aortic cusps. The myocardium showed nothing of note. A few atheromatous patches were evident in the coronary arteries. There was no evidence of syphilis in the thoracic aorta. The left lung showed collapse of its lower lobe due to a collection of about one pint of blood in the pleural cavity. The abdominal cavity contained about two pints of deeply blood-stained serous fluid. The liver was slightly atrophied; the spleen was more than twice its normal size.

Pushing forward the lesser peritoneal sac and appearing between the gall-bladder and the hepatic flexure of the colon

ant fluid remained cloudy. When examined after a large Gram-positive bacillus was found, but on tures only irregular Gram-negative forms and spores sent.

culture was made into 2 per cent. maltose broth, r 18 hours' incubation 0·5 c.cm. was injected intra- rly into the leg of a mouse and a guinea-pig. Both died after 18 hours. The muscular tissue was l down to the bone, which was visible. The liver gs were placed in a Petri dish and incubated. In 24 hey were completely liquid. Smears from the site tion showed both the large Gram-positive bacillus rminal spored organisms. The guinea-pig's heart howed morphologically only the large bacillus.

Summary of Results.

marising the results to date, it will be noted apparently a very mixed culture was grown the foreign body; that this was purified by g for ten minutes; that at least two forms were present after single colony culture; and that the blood of the dead animal showed, apparently, one. Of course, morphological appearances are tle value among anaerobes.

e guinea-pig's heart blood was next incubated in rtson's medium. Digestion both of it and of coagulated a was rapid. Gas was not formed. Forty-eight hour res had no effect on three guinea-pigs. One c.cm. of an ur culture, however, quickly produced massive œdema dquefaction of tissues in three guinea-pigs. These were d, as the lesions were obviously of the same type as those er recorded. Two c.cm. of *B. welchii* antiserum and cm. of the patient's serum failed to give any protection n injected simultaneously with 2 c.cm. of culture. c.cm. of a 12-hour culture was filtered through a Seitz injected intravenously into a rabbit; the animal ained perfectly well.

n further subculture the strain became again iously mixed. Profuse gas formation and black- ng and the medium suggested *B. sporogenes* and erminal spored form *B. cochlearius*. However, a re-bearing anaerobic motile Gram-positive bacillus, efying living tissue in early, but not in late, ures, was present. Only one known organism, rare *B. histolyticus* of Weinberg and Séguin,[2] orms with these findings. It was found by them a case of gas gangrene during the war, and has nce been found in the soil and in the fæces.[3] This organism, together with several other anaerobic forms not identified, but probably including *B. sporogenes* and *B. cochlearius*, had been present in a patient's wound, without sinus formation, for more than eleven years. Certainly no lesions resembling those found in the animals were found in him. The hæmolytic streptococcus and the staphylococcus were quite sufficient to cause his symptoms. But the results, together with former ones, indicate that the spores of anaerobic bacteria, even of pathogenic types, may persist in war wounds for many years. Whether they might ever have become pathogenic is a question on which these results throw no light. The "Medical History of the War,"[1] however, states that serious and even fatal "flares" have followed such operations as these.

My thanks are due to Mr. J. B. Harman, who assisted in the bacteriological work here described, and to Sir Cuthbert Wallace for permission to publish this case.

A GUINEA SCHEME AT KING'S COLLEGE HOSPITAL.—The governors have adopted a new rule relating to guinea subscribers. Under this scheme subscribers who become private patients will be entitled to deduct the whole amount of their subscriptions from the cost of treatment.

DERBYSHIRE WOMEN'S HOSPITAL.—The Duke of Devonshire recently opened the new buildings of this hospital, which have cost about £13,000. There are over 40 beds, including a recovery ward, an X ray department, and seven sun balconies.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society, held on Oct. 28th, the chair was taken by Mr. DONALD ARMOUR, the President, and Mr. A. E. HAYWARD PINCH opened a discussion on

RADIUM THERAPY.

The early hopes of radium as a panacea for all ills, he said, had not been realised, but its subsequent derision had been equally unjustified. It was now universally recognised as a valuable and in many respects unique addition to the surgeon's armamentarium. He deprecated strongly the loose and indiscriminate use of the phrase "radium cure for cancer." Radium aided surgery but did not abolish it. Radium therapy—the treatment of disease with radium—was a very wide subject, and meant a great deal more than the treatment of malignant disease by gamma radiation. It could be divided into two main divisions: superficial, which might almost be termed beta radiation, and gamma radiation therapy with apparatus so screened as to emit only a minute portion of hard beta or pure gamma radiation. Superficial therapy was subdivided into the treatment of malignant and non-malignant conditions. It was extremely useful for a variety of disorders not very important in themselves, but sources of extreme annoyance to the patient—e.g., pruritus, corns, acute tender papillomata of the feet, and the acute tender papilloma of the ear which so effectively prevented sleep. One radium treatment was an absolute specific for these nine times out of ten. It might act as a charm occasionally in a case of lupus vulgaris which did not respond to light. It would not cure lupus erythematosus, but would improve the appearance remarkably and avert recurrence for many years. It was also extremely useful in bad keloids, such as were sometimes left by vaccination; it would at least flatten the scar. Diffuse cavernous nævus responded in an almost miraculous fashion. The malignant condition in which radium therapy was most useful was rodent ulcer. A cure could almost be guaranteed in 95 per cent. of cases with one screened treatment. Mycosis fungoides was another condition in which the outlook had been completely revolutionised by radium. Epithelioma of the cornea could not be needled, but an unscreened exposure of about an hour would practically cure every case; the growths were proliferative rather than penetrative. Sarcoma of the eye also benefited. He had treated dermatitis pigmentosa successfully.

Deep Radium Therapy: Gamma Radiation.

Of non-malignant conditions the first was menopausal hæmorrhage, in which deep gamma radiation was marvellous and an almost certain cure. Cure, however, must not be promised to a young girl with essential uterine hæmorrhage. Tuberculous adenitis, if treated before suppuration had occurred, could almost certainly be cured without disturbance of the skin or of the patient. Aspiration followed by radiation gave good results. Radium would not cure splenic leucocythæmia but would materially alleviate it and prolong life; the spleen receded from the iliac fossa to its normal impalpable position, unless there had been a good deal of fibrosis. The period of life of a patient with lymphadenoma was put in Osler at two years; after radium treatment it might be put at four or five years, and some cases had lived for six years. The glands disappeared and the patient gained in comfort and happiness.

The treatment of malignant disease by gamma radiation had been much discussed in the press.

There were only two types of case in which he would hesitate to advise radium instead of operation: when the growth occurred in a very œdematous zone, and when there was a strong syphilitic taint, which might cause intense destructive reaction. He described three typical problem cases, for all of which he would use radium: an endocervical carcinoma in a working-class mother; a mammary cancer in a society woman who feared disfigurement; and a cancer of the tongue in a man of 60. In 90 per cent. of cases radium would cause disappearance of a growth in uterus, breast, or tongue in five or six weeks. Removal of the primary growth, however, was far from constituting cure. Mr. Pinch confessed that he did not know the best method of treating the glands, whether by needles and seeds in and around, contact radiation from screened applicators, cross-fire or focal application. In some cases the result was remarkable, in other apparently identical cases nothing happened. One of the greatest problems of radium therapy was the successful treatment of secondarily infected glands. He had treated some hundreds of cases of carcinoma of the œsophagus and never cured one. One difficulty was to determine the exact extent of the disease; the bismuth meal gave length and apparent width, but no indication of the depth of penetration of the mediastinum. He had seen five cases diagnosed as cardiospasm; even a very thorough œsophagoscopy had not revealed any growth, but in four of them autopsy had shown a growth just behind the posterior wall of the stomach. Radium therapy could not be learnt in a week, however skilful the tutor or apt the pupil. In a year the pupil might possibly know enough about it not to do any mischief —but no more. There was no antidote to an overdose of radium: radium therapy must not be embarked on lightly. In Talleyrand's words "Pas trop de zèle," or—"For God's sake be careful." The Radium Institute would always be pleased to place its knowledge at the disposal of anyone who asked for it.

The Physicist's Attitude to Radium Therapy.

Prof. SIDNEY RUSS suggested that when a tube containing radium was put into the body, whether into malignant or non-malignant tissues, certain quite definite physical conditions had to be coped with. The question was how far the tube would have the desired action. Experimentally, parts of the irradiated tumour could be removed to test their viability in a susceptible animal. It was found that the cells had not been killed but would not grow. Radium did not cauterise cells, but caused some action which subsequently prevented proliferation. Doubling the dose did not double the range of lethal action, nor could the useful action of a tube be extended by leaving it in indefinitely, owing to local damage. Prof. Russ then showed diagrams illustrating how the intensity of a tube at various distances was calculated from the sine of the angle subtended by the tube. The intensity fell off very rapidly, so tubes were "staggered" in a line to supplement each other. It was astonishing how large an area could be uniformly irradiated by this method. By measuring the lethal range of a tube in animal tissues a fairly clear idea could be obtained of its effect on human tumours. It was impossible to think of the Stockholm technique as one that dealt effectually with extensions of the primary growth. An interesting feature of the development of radium therapy was the reduction of the intensity used in the tubes. Strong tubes had given very bad results. The reaction was very much more favourable when small intensities were given for a long time, because dividing cells were more vulnerable to radiation than cells in other phases. Radiation did two things: it acted on the dividing cell so that the daughter cells were abnormal and did not grow into mature cells, and it prevented growing cells from reaching the stage of division. If the radiation were not carefully planned for its purpose the malignant cells would reassert themselves in the course of time.

Discussion.

Mr. DUNCAN FITZWILLIAMS felt that curietherapy was at present in such an early experimental stage that no dogmatic statements were justified. There were three great centres, each carrying out a different but perfectly stereotyped technique, and it was difficult to get anyone to experiment with unknown possibilities. As things were, radium was more abused than used, and more was to be learned from failures than from successes. He feared a commercial exploitation of radium which would make things much worse.

Dr. J. DOUGLAS WEBSTER showed a number of slides which illustrated successful radium treatment of malignant cases and various methods of technique. He referred to the grave danger of radium burns, and said that large doses should be applied from a distance of 4–6 cm.; this gave more effect on the depth and less on the surface. He commented on the conflict of opinion about the different effects of different wave-lengths in different parts of the body, and the various techniques used to protect the areas of secondary spread in mammary cancer. In his experience failure was usually due to faulty technique in dosage. It was absolutely necessary to examine the patient every three months for five years and to treat recurrences promptly. Dr. Webster urged the necessity of further research, particularly into the technique of application, and the exploration of new methods.

Sir JAMES DUNDAS-GRANT said he had been impressed with the extraordinary relief afforded by radon to patients with cancer of the œsophagus and larynx. He said he had also been much impressed by the results of X rays in laryngeal carcinoma, describing several cases. He thought that operation followed by X rays was coming into vogue.

Mr. ARTHUR EDMUNDS said that no speaker had tackled the three problems propounded by Mr. Pinch. He would do a radical operation on the society woman and send her to a firm of corset-makers to be fitted with a suitable substitute for the lost breast. He would do a complete dissection of the glands of the neck of the tongue case and insert radium.

Mr. WILLIAM GILLIATT, speaking of Mr. Pinch's first case, said that endocervical carcinoma was seldom diagnosed in the consulting room. It always extended very much further than the manual examination would suggest. Radium was nowhere more useful than in gynæcological practice. Preoperative irradiation was nearly always beneficial; it caused disappearance of hypertrophic growths and healing of ulcerative growths, and greatly diminished the risk of the post-operative sepsis which caused the death of many Wertheim cases. There was a potent individual factor in the reaction to radium.

Dr. C. E. LAKIN preferred radium to X rays for splenomegalic leukæmia; it seldom caused constitutional disturbance, whereas prolonged deep X rays might make people really ill.

Reply.

Mr. PINCH, replying, proposed that one meeting each year should be devoted to a discussion of radium failures and mistakes; the results would be of great importance. There was no one technique in radium treatment; it was in a state of flux. Everyone must work intelligently, record successes and failures, and have the results collated and scientifically analysed after five years. He thought that personal idiosyncrasies played a larger part in gynæcological cases than in general surgery.

ABERDEEN ROYAL INFIRMARY.—By means of a special appeal, Sir Andrew Lewis, Lord Provost of Aberdeen, recently raised over £400,000 for the erection of a new infirmary. It is now stated by the board of directors of the institution that, in consequence of altered plans and increased estimates, the cost of the work will be £600,000.

ROYAL SOCIETY OF TROPICAL MEDICINE.

TROPICAL MEDICINE AT THE TURN OF LAST CENTURY.

IN his presidential address to the Fellows on Oct. 18th Dr. G. CARMICHAEL LOW passed in review the gains to tropical medicine made between 1894 and 1914. He recalled how, at the turn of the century, a brilliant company of explorers in the new world of tropical pathology opened up by Patrick Manson rapidly extended and consolidated his pioneer observations of the part played by insects in carrying disease.

Malaria and Mosquitoes.

Manson left Hong-Kong in 1889. He had retired from practice and gone to live in Scotland, but the great depreciation of the Chinese dollar in 1890 brought him back to practice again and to London. Here, four years later, Ronald Ross sought him out. In Bangalore in 1889 Ross had studied malaria, but failed to confirm Laveran's discovery of the malaria parasite. Manson now showed him the parasite and withal explained his famous mosquito-malaria hypothesis which had been born of and fostered by his pioneer work in Amoy in 1877 on the development of the embryos of *Filaria bancrofti* in the tissues of the mosquito. In 1894 the predominant opinion was that "flagellation" of the malaria parasite signified, and was the product of, the parasite's death and disintegration. Manson taught the contrary: "Since the flagella appear only when malarial blood gets outside the body," he said, "their purpose must be to continue the life of the parasite in the outer world . . . for the purpose of infecting mosquitoes which suck the blood of patients." This was a chain of reasoning from which Ross found it impossible to escape; and in the upshot, on returning to India in 1895, he, for his part, began those researches which eventually justified the hypothesis that malaria was transmitted by mosquitoes. But before this historic achievement MacCallum, in 1897, settled all controversy about the exact nature of the "flagella" by showing that they were microgametes. On August 20th and 21st, 1897, Ross, in Secunderabad, made an important discovery. In the stomach of two "spotted-winged mosquitoes," bred from larvæ and fed on a patient with malaria crescents in the blood, he found certain cells containing pigment granules indistinguishable from those seen in malaria parasites; and a month later he found like cells in another species of anopheles—also bred from larvæ and fed on malarial blood. This shining discovery Ross reported promptly to his chief in the Madras Presidency; and now, with the solution of the great problem in his grasp, he was given urgent orders to proceed at once to Rajputana where the dry cold weather put an end to mosquito work. At this juncture Manson interceded with the India Office in London, with result that in January, 1898, Ross was placed on special duty for six months to continue his malaria research. He arrived in Calcutta in the following February, but now armed with MacCallum and Opie's proof that the crescents were sexual forms and not special "sporulating" ones. Human malaria was scarce in Calcutta, so, acting on Manson's suggestion, Ross turned to the malaria of birds, and here found material in plenty. In March he had tracked down the species of mosquito [illegible]nable of carrying the malaria parasite of birds, [illegible] within a few more weeks had traced step by step [illegible] cycle of the parasite's development in this mosquito. In July, 1898, he telegraphed to Manson, who announced the discovery at the British Medical Association meeting in Edinburgh at the end of that month. But the "mugwumps" had not finished with Ross; again and quickly he was forced to discontinue malaria work. He was sent to Assam to investigate kala-azar, and thus, said Dr. Low, it fell to Grassi, Bignami, and Bastianelli, in Rome, to verify the great discovery for human malaria. This would not have been done at the time but for Ross's work—the Italian researches followed his, and were not independent of them.

Manson's Later Work.

In July, 1897, Manson was appointed Medical Adviser at the Colonial Office. His influence appeared in March, 1898, when the Secretary of State for the Colonies, Joseph Chamberlain, issued the first of his letters to the General Medical Council, the medical schools, and the governors of tropical colonies, urging the need of special instruction in tropical diseases. These letters led directly to the founding of the schools of tropical medicine in Liverpool and London before the end of the century—a lead since followed by many nations. In 1877 Manson, in Amoy, discovered the nocturnal periodicity of the embryos of *F. bancrofti* in human blood, and followed this up by showing that the embryos developed and underwent a metamorphosis in the thoracic muscles of the mosquito *Culex fatigans*. He surmised that the mosquito then died in water; the metamorphosed embryos escaped into the water, and through this medium entered man.

In 1899 Manson set Dr. Low the task of examining by serial section a number of mosquitoes which had fed on the blood of filarial human patients, and been kept alive for varying periods afterwards. They had been sent to Manson by Bancroft in Australia. In the heads of some of the mosquitoes, 12 to 20 days after feeding, metamorphosed embryos were found, and at first taken to be just aberrant wanderers. In March, 1900, a section was examined which had taken in the whole length of the proboscis—and there, lying along it, were two completely metamorphosed embryos. When it was shown to Manson he exclaimed: "If only I had known this before my mosquito-malaria theory—how it would have helped me!" The ball had been set rolling, and fast. In 1900–01, Reed, Carroll, and Lazear demonstrated in Havana that yellow fever was transmitted by the mosquito *Aëdes egypti* (*Stegomyia fasciata*). Lazear himself was bitten by one of these infected mosquitoes and died of yellow fever. The first and still the greatest triumph in practical prevention of tropical disease, the direct outcome of these discoveries, soon followed. Havana was completely rid of the secular scourge, and Gorgas was now armed with the knowledge which he expressed in the sanitary control that made possible the digging of the Panama Canal—where once malaria and yellow fever had signally defeated de Lesseps.

ROYAL SOCIETY OF MEDICINE.

SECTION OF UROLOGY.

UROLOGICAL STATISTICS.

AT a meeting held on Oct. 24th Mr. FRANK JEANS delivered his presidential address on Urological Statistics as a Criterion of Progress. He questioned the conclusions to be deduced from figures, because clinical surgery was not exact enough to be reduced to numbers. Medicine was a science, surgery an art, and general practice an inspiration. The essential to interpreting statistics was the realisation of the inconstant factors, which far outnumbered the constant factors. The constant factors were few. They were:—

1. The name of the disease, but even this was subject to differences in nomenclature.
2. The age of the patient.
3. The sex of the patient.

Beyond this the factors became more vague. They were:—

1. The duration of the disease; this figure, if given in weeks or years, ignored the fact that one man in a week may become as ill as another man in a year—the old fallacy of [illegible] fourth [illegible]dix.

2. The presence or absence of sepsis. This was difficult to measure, though in the war it had been roughly done by counting organisms in a microscopic field.
3. Concomitant diseases independent of obstructive urinary lesions.
4. The temperament of the patient; this frequently had determined the question of operation.
5. The weather. Kocher the elder said: "Never do a thyroidectomy on a foggy day."
6. The surgeon who does the operation, or in "pooled" statistics of various hospitals, a mixture of surgeons of very varying ability and skill.
7. The stage of the surgeon's career. Was it done when he was at the height of his daring, or at the height of his efficiency, or at the height of his fame? These were all peaks in the curve at different points in a surgeon's career (and in the careers of actors, violinists, and vocalists). A block of statistics from each of these three periods might or might not yield the same mathematical results as a block from the whole period of his career, but would be clinically different.

Certain factors that ought to make results better were considered by Mr. Jeans.

1. *Asepsis.*—Nothing had been added to the technique of the theatres at the Royal Infirmary, Liverpool, which was as perfect 25 years ago as is to be seen in any theatre to-day.
2. *Anæsthesia.*—It was true we had greater experience of a larger variety of methods, but it was only the increased choice that helped us to select the right method.
3. The greatest influence was increased knowledge of the *efficiency of the kidneys*, and therefore the knowledge when to operate. Many men were alive to-day because they had had preliminary drainage before prostatectomy.

There was one factor, not often mentioned, which might make the results of urologists look worse on paper, and that was the decentralisation of surgery, first from London to the big provincial cities, and later from them to smaller towns. The result of this was necessarily that the pure surgeons and the pure urologists, whether in London or in the teaching provincial schools, were getting a far higher proportion of difficult cases, the ordinary easy ones being done, selectively, by surgeons who were also general practitioners. Specialised experience therefore became qualitative as well as quantitative. Had a deep interest in one's own statistics any moral or immoral influence upon a surgeon's decision to operate upon a desperate case? Theoretically it had none; but surgeons were, after all, human. Impressions after the age of 40 were more valuable than statistics, always provided that the surgeon had not had the disease himself. Personal experience was graphic but misleading.

The results of urinary surgery had undoubtedly improved enormously, but it was difficult to prove this by figures. One should continue to aim high, but one had to choose between two poetical views—Shakespeare's "Striving to better oft we mar what's well." and William Watson's "To keep in sight perfection and adore the vision is the artist's best delight."

SECTION OF EPIDEMIOLOGY.

THIS Section met on Oct. 25th, with Dr. F. E. FREMANTLE, M.P., the President, in the chair, when a paper on

MODERN ASPECTS OF THE EPIDEMIOLOGY, PREVENTION, AND TREATMENT OF MALARIA

was read by Dr. S. P. JAMES. Malarial mortality, he observed, had decreased enormously in the last 100 years in North Europe, though chiefly because [illegible] many deaths were formerly ascribed to malaria [illegible]or. Deaths from this cause did, however, still [illegible] the [illegible]d, and in the same districts as were [illegible] the dividing [illegible]d malarial. Why were they so [illegible] and [illegible]eles were as prevalent as he had [illegible] growing [illegible]ere the feeding habits of these [illegible] the [illegible]? Great social improvements, [illegible]ose the [illegible]r housing had limited malaria, [illegible] in the cou[illegible]ces eight miles from a doctor, with bad houses, unceiled roofs, and no drainage, and to get rid of malaria in England better housing was of the first importance. Speaking of general paralysis, Dr. James mentioned a case infected with benign tertian in September but showing no reaction till a characteristic attack came on in April, a strikingly long incubation. He showed excellent photographs of a charcoal-burner's hut, a perfect mosquito trap, and of other houses in England in which mosquitoes had harboured and carried infection.

Sir MALCOLM WATSON said they had had good housing in Malaya but they had not got rid of their huge malarial death-rate till they had drained their areas. Drainage was required to destroy the larvæ of carrier species while they were together before they had turned into mosquitoes. People not living in the tropics could hardly appreciate the effects of tropical malaria which had depopulated great cities in Ceylon. Problems of malarial control were unending. He spoke of a district where the river had been embanked to avoid floods, and malaria had thereafter become worse, the floods having in the past carried away the larvæ in mass, while now these remained on the spot. —Dr. PHILIP MANSON-BAHR insisted on full use of quinine to prevent patients becoming carriers. —Dr. GORDON THOMSON said drainage and housing were both needed. People were mostly infected in their houses as Dr. James had said, and many bites were needed, for only 1 per cent. of mosquitoes were infected.—The recent reduction of malaria in the army in India through screening of barracks was mentioned with appreciation.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(*Continued from p. 880.*)

SECTION OF HISTORY OF MEDICINE.

IN a paper entitled

JOHN DALTON—EXPERIMENTAL PHYSIOLOGIST AND WOULD-BE PHYSICIAN

Dr. E. M. BROCKBANK, President of the Section, gave an account of the early life of the founder of the atomic theory as a schoolmaster at Kendal. Dalton had expressed in letters, two of which were published for the first time, the wish to become a physician. Having been discouraged by his relatives from entering the medical profession, he accepted an invitation to go to Manchester as teacher of mathematics and natural philosophy at the academy of that town. He remained there for about six years, and during that time used to discuss with the social reformer, Robert Owen, various religious and scientific topics, including his then undefined atomic theory. He soon became a member of the Manchester Literary and Philosophic Society, which was mainly composed of medical men, and took an active part in its proceedings. As the title of his papers showed, Dalton paid considerable attention to important physiological subjects to which he had been attracted by his interest in medicine. His contributions included papers on colour vision, the mind and its ideas and affections, respiration and the causes of animal heat, the effect of atmospherical pressure on the animal frame, and the quantity of food taken in health compared with the amount of the secretions during the same period. Dr. Brockbank concluded by giving some personal details relating to Dalton's dietetic habits, his colour-blindness, and his susceptibility to lead. His death, which took place in 1844, at the age of 78, was due to cerebral hæmorrhage.

Sir D'ARCY POWER read a paper entitled

Surgeons Who Were Never Surgeons.

By this he meant persons who had taken or obtained the degree of F.R.C.S. Eng., but had never practised as surgeons, and apparently had never intended to do so. He gave short biographical notices of such men. First amongst them was Richard Robert Madden, who became a Fellow in 1855. He was intimate with Lady Blessington's circle, and became a friend of Lord Byron and Count D'Orsay. He was a special correspondent in Lisbon for the *Morning Chronicle*, and was Colonial Secretary in Western Australia. William Guybon Atherstone—F.R.C.S. in 1863—was in danger of being forgotten in this country, but he did invaluable service in South Africa, where he made straight the paths for Cecil Rhodes. He advocated the Cape to Cairo railway, desired to see the telegraph carried overland, recognised the first diamond brought from Kimberley, and became a member of the Legislative Council in 1884. Robert James Stone left England for Natal as Superintendent of Education, became a meteorologist, and organised the scientific apparatus at the South Kensington Museum in 1870. George Redford—elected F.R.C.S. in 1869—was registrar of the Crystal Palace collection of sculpture, and devoted his life to the care and description of works of art. His son, George Alexander Redford, was well known as the official examiner of plays. The Bishop of Labuan—Dr. Francis Thomas McDougall—seemed to have been the only bishop of the English Church who passed the examinations and was admitted a Fellow of the Royal College of Surgeons of England. He was an eminent Churchman, a good doctor, and a first-class fighting man. Alfred Smee had the post of surgeon to the Bank of England specially made for him that the Bank might retain his scientific services. He invented "Smee's battery," a durable writing ink, a method of printing cheques and notes, and rendered it impossible any longer to split bank notes. He was, too, a physiologist interested in the electrical parts of the science, and had he still been alive would have been amongst the foremost electrical engineers. Whilst he was still a student he invented the "gum and chalk" splints, which were superseded by plaster-of-Paris, which in turn were replaced by celluloid.

Dr. T. WILSON PARRY (London) read a paper illustrated by lantern slides on

The Stimulus given by Religion to Surgery during the Third Epoch of the Neolithic Period.

He showed that during that period the operation of craniotrypesis (holing the cranium) was performed on the living human skull in order to facilitate the departure of demoniacal spirits. The dead were then buried in dolmens, so that these events could be accurately dated. Large numbers of holed skulls recovered from dolmens could be seen to-day in public and private museums in different parts of France. There were, however, only two skulls on record which could have been in any way dealt with for morbid conditions. It was clear that the religious operation for the setting free of evil spirits was performed first, and later opportunity was taken by the experience thus gained to correct pathological conditions, thus giving a start to cranial surgery, which otherwise would doubtless have been kept back for many centuries. Dr. Parry showed how a skull exhibiting evidence of the ritualistic operation could be differentiated from other holed skulls of prehistoric origin, and pointed out that it was entirely due to the spiritual conditions of that day, which necessitated a surgical procedure for the cleansing of the individual from evil spirits, that cranial surgery took its origin.

In a paper on

James Braid

Dr. GEORGE FLETCHER (Manchester) stated that details of Braid's life were scanty, and his writings were now very scarce. He was born on June 19th, 1705, at Ryelaw House, in a part of Fifeshire which was afterwards transferred to Kinross-shire by the Boundary Commissioners. He was qualified at Edinburgh in 1815, and in 1820 came to Manchester, where he died on March 25th, 1800. He had little connexion with official medicine at Manchester. He was not on the infirmary staff, nor was he a member either of the Literary and Philosophical Society or of the Medico-Ethical Association. His advocacy of hypnotism led to his being regarded as somewhat of a charlatan by his more disciplined brethren. He early specialised in the surgery of deformities, and was apparently the first in England at any rate to have performed tendon shortening in paralytic talipes. The demonstrations of a travelling mesmerist led him to investigate mesmerism, and having found something genuine in it he gave lectures in various parts of the country in order to convince the public and the profession of its safety and value. In 1842 he published a pamphlet "Satanic Agency and Mesmerism," in which he replied to the criticisms which the Rev. H. M'Neile had made in a sermon. Next year appeared Braid's chief work, "Neurypnology." In it he defined the meaning of the word "hypnotism," which he himself had coined, and described the phenomena of the hypnotic state and his mode of inducing it. He devoted a large section to the investigation of the alleged phenomena of phrenology, but his results were discordant; in a later essay he repudiated a belief in phrenology. The second part of the volume was occupied by descriptions of cases of disease which he had treated with more or less success by hypnotism. Most of Braid's writings were occasional and controversial in character. He did not live to give a final account of his researches. In his later works he laid less emphasis on fatigue as a factor in exciting the hypnotic state, and recognised the rôle of suggestion in its induction, control, and therapeutic application. He did not, of course, discover that state, nor was he the first who contended that it was wholly subjective in character. His great merit lay in the fact that he stripped mesmerism of its baseless and occult extravagances, and reissued it in the form of hypnotism for the service of the physician and the psychologist. The subsequent development of hypnotism in France and elsewhere was largely the outcome of his labours. Braid's interests were not confined to hypnotism, which he employed only in the minority of his patients. The use of arsenic in trypanosomiasis was due to a suggestion which he made to Dr. Livingstone. He performed a Cæsarean section in 1847. Sanitary matters occupied his attention, and he kept in touch with natural history during his Manchester life.

Dr. E. BOSDIN LEECH gave an account of

Charles Harrison Blackley (1820–1900).

Blackley was a pioneer in hay-fever research, who, according to Dr. Leech, had not had sufficient recognition for his researches and discoveries. He took up medicine when 35 years old, and spent the remainder of a long life experimenting on the cause and treatment of the disease from which he himself was a sufferer. His work was all the more praiseworthy since he was a general practitioner with a large practice, and a really successful experiment on himself meant that he was incapacitated from work for the day. He was the first to prove definitely that pollen was the cause of the trouble, and that though grasses were the most frequent cause, still the pollen of other plants brought it on in varying, though definite, degrees. Others had surmised; but he experimented and proved. His ingenuity in devising apparatus, both for judging the effects of pollen and preventing it reaching the nasal mucous membrane, was very great. He practised in Manchester, so that the meeting was a suitable one for recognition of his work. Up to the present his fame was chiefly in America, where his work was more appreciated than at home.

WARMINSTER COTTAGE HOSPITAL.—Last week the Marquess of Bath, who gave the site, opened a new cottage hospital at Warminster. The old building, which has been in use for 63 years, was originally a farmhouse. The wards are all on the ground floor and one of them is named after Dr. R. L. Willcox, who has for many years been associated with the hospital.

Reviews and Notices of Books.

THE EXTRA PHARMACOPŒIA OF MARTINDALE AND WESTCOTT.

Nineteenth edition. Revised by W. HARRISON MARTINDALE, Ph.D., Ph.C., F.C.S. Vol. II. London: H. K. Lewis and Co., Ltd., 1929. Pp. 759. 22*s.* 6*d.*

A NEW edition of the second volume of the Extra Pharmacopœia appeared last week, and represents the results of four years' work; the first volume was issued a little over a year ago, and in its sequel Dr. Harrison Martindale has exercised similar care in the revision and arrangement. How necessary this is he points out in some prefatory words, reminding us of the overwhelming bulk and character of the scientific literature of to-day. This fact militates against the conciseness for which the Extra Pharmacopœia is famous, and the author is to be commended especially for one direction in which he has secured the invaluable quality—some of the relatively old material is purposely retained while references are given to newer views, perhaps destined to supersede existing ones, but still needing confirmation. In such cases the reader is directed to previous issues of the Extra Pharmacopœia for information as to the omissions made necessary in order to avoid overloading. As a matter of fact Dr. Martindale has managed to abstract with brevity and precision much of the world's literature germane to his objects, and, as showing the extent to which the compilation is up to date, it may be mentioned that several articles which were published in our issues of Sept. 29th and Oct. 5th of this year have been laid under contribution.

The first volume of the Extra Pharmacopœia is concerned chiefly with information upon the clinical use of chemicals and drugs, their characters, dosage, and methods of prescription, while the present volume sets out developments in investigations, details of experimental research, and certain machinery for diagnosis. One matter among many dealt with by laboratory investigation is mould inhibition by means of various preservatives, a complication which has constantly given practical anxiety in the preparation of pharmaceutical products and foodstuffs generally. An equally important section from the public point of view deals with the antiseptic powers of various chemicals. This chapter is particularly informatory, while it makes pleasant reading for ourselves because stress is laid upon the value of the work of the late S. A. Vasey, which was done at the instigation of THE LANCET and which, with modifications, has been employed in these investigations. Dr. Martindale points out that while there is in this country an inclination to discredit disinfectants as weapons against the germs of disease, the reason of this may be that under the Act of 1908 any useless preparation may be sold to the public without proof that it contains, for example, high germicidal power, that it makes or forms a due emulsion with water, and that it is not affected to a mischievous degree by temperature. The importance of distinguishing antiseptic action from germicidal power is pointed out, and a list of the more potent antiseptics arrived at by recent experiment is given alphabetically, with details of the researches. The information in these pages is of the first practical value.

Another section that will be immediately consulted is that dealing with milk analysis. We have here a résumé of the various Acts of Parliament, regulations, and official publications through which it is endeavoured to secure that the public obtain a milk of good quality and average chemical composition. The grading of milk is clearly dealt with, and the bacteriological standards of the various grades are given, as well as an explanation of the tuberculin tests in cattle, special reference to intradermal tests being added. The notes on the pasteurisation of milk are full, and we may commend the impartiality with which the views on a vexed subject have been collated. The author puts forward a suggestion which we believe is novel—namely, that the consumer might be supplied with milk refrigerated on the farm and delivered to him within a few hours of milking in thermo-isolated vessels. His proposal is backed by experiment, and he may be congratulated upon an idea which could be realised practically by the provision of cheap thermos flasks, which must also be strong and returnable.

The scope of the Extra Pharmacopœia, through the successful dispersal of many large editions, is familiar to all our readers; it remains to say that this addition to the series is, like its predecessors, a clear and authoritative publication, of the highest value to all medical men, and indispensable to many of us.

THE TRAUMA OF BIRTH.

By OTTO RANK. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1929. Pp. 224. 10*s.* 6*d.*

IT is agreed by psycho-analysts that what may be either memories or fantasies of birth play a part in the genesis of pathological anxiety and commonly emerge in the process of analysis, though to anyone not analytically minded the existence of the actual memory in the unconscious is not easily credible. Otto Rank, a Viennese analyst of repute, finds that the unconscious is right "where we have dared to follow it only hesitatingly and incredulously," and that in a number of cases the patient repeats his own birth for the most part quite faithfully in all its details. From this starting-point Rank explores the worlds, of myth, religion, art, and philosophy, finding everywhere proof that the primary trauma of separation from the mother underlies their development and manifestations. Without rejecting his original observations we may doubt whether he has done more than other single-minded enthusiasts who, exploring the same worlds, have found evidence for their own theories of human development, and we turn more expectantly to the medical implications of his proposition. He shows in his early chapters a fault common in psycho-analytical writings—perhaps due to the lack of the discipline of effective criticism—for it is sometimes difficult to distinguish established observations from deductions or mere obiter dicta. A statement on page 28 is startling in its non sequitur, when we read that the fact of the newly hatched young of a Cichlid fish taking refuge at night in the throat-pouch of the mother "proves that physiological sleep throughout the animal kingdom is a temporary return to the mother's womb." The writer should not thus make more difficult the task of giving impartial consideration to views that, as psycho-analysts freely admit, inevitably arouse opposition. The fault becomes less apparent in later chapters, as if the one frankly headed "Philosophic Speculation" had enabled the author to sort out his material and prepare the way for his lucid discussion of psycho-analytical knowledge and the therapeutic aspect. He has already claimed (page 4) that his analyses are comparatively short and now he boldly presents the opponents of analysis with the admission that he considers analysis is now in a position to free itself to an extensive degree from the work of investigation (that is, we assume, in the individual case) and to sever the Gordian knot of the primal repression at one cut, thus rendering the analytical process easier and quicker. It is for his fellow workers to decide how far this departure from accepted technique will be approved; his discussion shows an appreciation of the difficulties and limitations of therapy.

From the analytical point of view the book is important inasmuch as it deposes the Œdipus motif from its central position and makes it secondary to the birth experience. Erasmus Darwin, describing the reactions of the child at birth, suggested that the sensations then experienced might serve as the prototype of fear throughout life. By those who accept their observations the possibility of this biological memory on the part of the organism will be confirmed by Rank and his colleagues, who attempt to show that the experience is actually conserved in the unconscious and is accessible to their methods of approach. The book is obviously intended only for those who have already travelled far along the same path as the author, and for them it should be full of interest.

AFTER-TREATMENT OF OPERATIONS.

Fifth edition. By P. LOCKHART-MUMMERY, F.R.C.S. Eng., M.A., M.B., B.C. Cantab., Senior Surgeon, St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum. London: Baillière, Tindall and Cox. 1929. Pp. 281. 7*s.* 6*d.*

THE appearance of a fifth edition is sufficient evidence that this book has proved of great value in the past. It has provided house surgeons and practitioners with just the kind of information about after-treatment that they need, and has given them details of the complications they may expect to meet and of the ways to deal with them when they arise. Unfortunately, in spite of the assurance in the preface that it has been brought up to date, that part of modern practice which is based on new knowledge is not given adequate prominence. For example, we can find no word about massive collapse of the lung, probably the commonest of the important pulmonary complications of operations. In the section on thyroid operations and their after-treatment iodine is not mentioned, while in that on pulmonary embolism and its treatment the word morphia does not occur. The article on surgical shock contains no account of histamine and its action; and while the statement on p. 99 of the same article that "the only form of transfusion which is permanently effective is human blood" is no doubt merely the author's somewhat dogmatic way of saying that a colloid solution remains in the vessels longer than a crystalloid one, gum solution has surely proved of sufficient value to be worthy of mention. In the discussion of the likelihood of gangrene if the main artery of the limb is ligatured for secondary hæmorrhage, no note is taken of the valuable war experience that simultaneous ligature of the vein materially lessens the risk. Finally, the insertion of a drainage-tube after the radical cure of hydrocele is not generally considered necessary.

That the radical of to-day is the conservative of to-morrow is a commonplace of politics, and although Mr. Lockhart-Mummery is justified in claiming credit for having advocated the shortening of the bed-period after the simpler abdominal operations from the three weeks of long ago to ten days, yet this period is now considered unnecessarily long by many surgeons. A few misprints need correction, such as "arthritis" on p. 54, where "arteritis" is meant, and "internal appendix" instead of "interval appendix" on p. 124. The book is written in a readable if somewhat dogmatic style, and it is only because it contains so much valuable information that it seems worth while to call attention to the need for incorporating some of the recently acquired knowledge which has been overlooked.

ANATOMY AND PHYSIOLOGY OF CAPILLARIES.

By AUGUST KROGH. Second edition. New Haven: Yale University Press; London: Humphrey Milford, Oxford University Press. 1929. 101 text figures. Pp. 422. 18*s.*

SINCE the first issue of this book in 1922 general interest in capillaries has much increased and a good deal of fresh and important work has been done, no doubt stimulated for the most part by the book itself. Specially notable are the researches of Landis on the quantitative measurement of skin permeability and of Lewis and his co-workers on the reaction of the skin to injury. Of these Prof. Krogh takes very full notice in this revised edition which in other ways as well is to a large extent rewritten. As before, it has the characteristics of its author. He is anxious everywhere to get some sort of quantitative idea of what is going on and to what extent, accurate if possible, but he shows over and over again that rough approximations are better than nothing at all. And he is not afraid of his imagination. What makes the book such good reading (which it certainly is) is not so much what he tells us as known, but his suggestive comment on what might be found out. He accepts Rouget cells as elements in the capillary wall of proved individuality, responsible for changes in calibre. And naturally a great deal of attention is given to Lewis's H-substance, though it does not seem to have occurred to Krogh that the phenomena of inflammation consequent on a clean aseptic skin wound have for many years been recognised as proving by exclusion that inflammation may be caused by the products of cell injury. Nor does he appreciate when he comments on the extreme whealing activity of the "poison" of the mosquito that this is an anaphylactic reaction which fits quite elegantly into the histamine saga.

DERMATOLOGY.

Précis de Dermatologie. Fourth edition. By J. DARIER, Médecin hon. de l'Hôpital Saint-Louis; Membre de l'Académie de Médecine. Paris: Masson et Cie. Pp. 1102. Fr.100.

FROM its first appearance in 1908 this work has occupied a distinguished position among dermatological text-books, and has been translated into four foreign languages. The collection of material and the preparation and selection of suitable illustrations for an up-to-date dermatological text-book is a task demanding not only much labour and time but also a comprehensive knowledge of current literature. Dr. Darier has given all of these freely, and has been in a position to enrich his book by accounts of his own classical contributions to the science of dermatology. The publishers have made a list of these in an appendix. This list reminds us that it is mainly to Darier that we owe the recognition and classification of the tuberculides, while his work on the sarcoids has justified the inclusion of a special type under his name (Darier-Roussy), while dermatologists all over the world speak of Darier's disease when referring to the condition which he has modestly called "psorospermose folliculaire végétante." Darier's more recent contribution to the histology of cutaneous epitheliomata goes far to explain the relative malignancy of the various types, and deserves more consideration than it has yet received from surgeons and radiotherapeutists.

In the augmented fourth edition of his text-book he has thoroughly modernised and largely expanded the sections on urticaria, eczema, parasitic and mycotic infections, &c., and has added a new chapter on diseases due to filtrable virus—e.g., herpes zoster—and another on dermatoses of autotoxic origin—e.g., prurigo and pruritus. The text throughout is brilliantly composed and arranged, and the sections on eruptions will stand as masterpieces of clinical phraseology. To read them is a relaxation rather than a labour, and so simple is the choice of words and idiom that a dictionary will seldom be required, even by those who do not read French easily. The one blot on the work is the old-fashioned method of reproducing the excellent illustrations and the absence of coloured plates.

THE MYSTERY AND ART OF THE APOTHECARY.

By C. J. S. THOMPSON, M.B.E. London: John Lane, The Bodley Head, Ltd. 1929. Pp. 287. 12*s.* 6*d.*

LAST year Mr. Thompson, who is honorary curator of the Historical Section of the Museum of the Royal College of Surgeons of England, gave us a valuable historical study of the quacks of old London. He now tells the history of the apothecary from the earliest times, tracing his subject from Assyrian, Egyptian,

Reviews and Notices of Books.

THE EXTRA PHARMACOPŒIA OF MARTINDALE AND WESTCOTT.

Nineteenth edition. Revised by W. HARRISON MARTINDALE, Ph.D., Ph.C., F.C.S. Vol. II. London: H. K. Lewis and Co., Ltd., 1929. Pp. 759. 22*s.* 6*d.*

A NEW edition of the second volume of the Extra Pharmacopœia appeared last week, and represents the results of four years' work; the first volume was issued a little over a year ago, and in its sequel Dr. Harrison Martindale has exercised similar care in the revision and arrangement. How necessary this is he points out in some prefatory words, reminding us of the overwhelming bulk and character of the scientific literature of to-day. This fact militates against the conciseness for which the Extra Pharmacopœia is famous, and the author is to be commended especially for one direction in which he has secured the invaluable quality—some of the relatively old material is purposely retained while references are given to newer views, perhaps destined to supersede existing ones, but still needing confirmation. In such cases the reader is directed to previous issues of the Extra Pharmacopœia for information as to the omissions made necessary in order to avoid overloading. As a matter of fact Dr. Martindale has managed to abstract with brevity and precision much of the world's literature germane to his objects, and, as showing the extent to which the compilation is up to date, it may be mentioned that several articles which were published in our issues of Sept. 29th and Oct. 5th of this year have been laid under contribution.

The first volume of the Extra Pharmacopœia is concerned chiefly with information upon the clinical use of chemicals and drugs, their characters, dosage, and methods of prescription, while the present volume sets out developments in investigations, details of experimental research, and certain machinery for diagnosis. One matter among many dealt with by laboratory investigation is mould inhibition by means of various preservatives, a complication which has constantly given practical anxiety in the preparation of pharmaceutical products and foodstuffs generally. An equally important section from the public point of view deals with the antiseptic powers of various chemicals. This chapter is particularly informatory, while it makes pleasant reading for ourselves because stress is laid upon the value of the work of the late S. A. Vasey, which was done at the instigation of THE LANCET and which, with modifications, has been employed in these investigations. Dr. Martindale points out that while there is in this country an inclination to discredit disinfectants as weapons against the germs of disease, the reason of this may be that under the Act of 1908 any useless preparation may be sold to the public without proof that it contains, for example, high germicidal power, that it makes or forms a due emulsion with water, and that it is not affected to a mischievous degree by temperature. The importance of distinguishing antiseptic action from germicidal power is pointed out, and a list of the more potent antiseptics arrived at by recent experiment is given alphabetically, with details of the researches. The information in these pages is of the first practical value.

Another section that will be immediately consulted is that dealing with milk analysis. We have here a résumé of the various Acts of Parliament, regulations, and official publications through which it is endeavoured to secure that the public obtain a milk of good quality and average chemical composition. The grading of milk is clearly dealt with, and the bacteriological standards of the various grades are given, as well as an explanation of the tuberculin tests in cattle, special reference to intradermal tests being added. The notes on the pasteurisation of milk are full, and we may commend the impartiality with which the views on a vexed subject have been collated. The author puts forward a suggestion which we believe is novel—namely, that the consumer might be supplied with milk refrigerated on the farm and delivered to him within a few hours of milking in thermo-isolated vessels. His proposal is backed by experiment, and he may be congratulated upon an idea which could be realised practically by the provision of cheap thermos flasks, which must also be strong and returnable.

The scope of the Extra Pharmacopœia, through the successful dispersal of many large editions, is familiar to all our readers; it remains to say that this addition to the series is, like its predecessors, a clear and authoritative publication, of the highest value to all medical men, and indispensable to many of us.

THE TRAUMA OF BIRTH.

By OTTO RANK. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1929. Pp. 224. 10*s.* 6*d.*

IT is agreed by psycho-analysts that what may be either memories or fantasies of birth play a part in the genesis of pathological anxiety and commonly emerge in the process of analysis, though to anyone not analytically minded the existence of the actual memory in the unconscious is not easily credible. Otto Rank, a Viennese analyst of repute, finds that the unconscious is right "where we have dared to follow it only hesitatingly and incredulously," and that in a number of cases the patient repeats his own birth for the most part quite faithfully in all its details. From this starting-point Rank explores the worlds, of myth, religion, art, and philosophy, finding everywhere proof that the primary trauma of separation from the mother underlies their development and manifestations. Without rejecting his original observations we may doubt whether he has done more than other single-minded enthusiasts who, exploring the same worlds, have found evidence for their own theories of human development, and we turn more expectantly to the medical implications of his proposition. He shows in his early chapters a fault common in psycho-analytical writings—perhaps due to the lack of the discipline of effective criticism—for it is sometimes difficult to distinguish established observations from deductions or mere obiter dicta. A statement on page 28 is startling in its non sequitur, when we read that the fact of the newly hatched young of a Cichlid fish taking refuge at night in the throat-pouch of the mother "proves that physiological sleep throughout the animal kingdom is a temporary return to the mother's womb." The writer should not thus make more difficult the task of giving impartial consideration to views that, as psycho-analysts freely admit, inevitably arouse opposition. The fault becomes less apparent in later chapters, as if the one frankly headed "Philosophic Speculation" had enabled the author to sort out his material and prepare the way for his lucid discussion of psycho-analytical knowledge and the therapeutic aspect. He has already claimed (page 4) that his analyses are comparatively short and now he boldly presents the opponents of analysis with the admission that he considers analysis is now in a position to free itself to an extensive degree from the work of investigation (that is, we assume, in the individual case) and to sever the Gordian knot of the primal repression at one cut, thus rendering the analytical process easier and quicker. It is for his fellow workers to decide how far this departure from accepted technique will be approved; his discussion shows an appreciation of the difficulties and limitations of therapy.

From the analytical point of view the book is important inasmuch as it deposes the Œdipus motif from its central position and makes it secondary to the birth experience. Erasmus Darwin, describing the reactions of the child at birth, suggested that the sensations then experienced might serve as the prototype of fear throughout life. By those who accept their observations the possibility of this biological

THE LANCET.

LONDON: SATURDAY, NOVEMBER 2, 1929.

THE RENAISSANCE OF GENERAL PRACTICE.

WHETHER we like it or not, the centre of gravity of medicine is shifting from the home to the hospital and clinic. The first result of this is that the profession will be unable to go on doing its hospital work for nothing and will increasingly demand payment for services rendered in institutions; the second result is a narrowing of the confines of general practice which will ultimately destroy the efficiency of all who are isolated from hospitals. The problem of payment for institutional treatment is being solved on orderly lines in the course of social evolution, but the problem of the private practitioner's isolation presents itself urgently in connexion with the Local Government Act which will come into force in April. It may not be strictly true to say, with one of the speakers at last week's Panel Conference, that this Act will provide hospitals for everybody, from duke to dustman, but it will certainly set free a very large number of beds to meet the public demand. This will have the effect of popularising hospitals still further, and if no attempt is made to bring the general practitioner into their working it will separate him yet more widely from truly general practice. If the family doctor is to look after nothing but minor complaints, if he is to surrender his patient during every illness, if he is to be kept out of the multifarious activities of the public health service, if he is to have no access to special means of investigation and treatment, then he stands little chance of being a good doctor. While very many have these facilities at cottage hospitals and elsewhere, and make good use of them, the majority of medical men are in no direct relation with hospitals. If local authorities choose the easy course and indiscriminately staff all their institutions with whole-time officers, the present opportunity of a renaissance of general practice will be lost—and such an opportunity may not occur again. It was on some such conclusion that the Panel Conference passed a resolution requiring an institutional position for the family practitioner.

But, of course, it is one thing to pass resolutions and quite another to translate them into action. What sort of hospital is the general practitioner to enter, and what is he to do when he gets there? Clearly no one would care to thrust him into the organisation of the great voluntary hospitals, and it may be asked whether he has in fact a function in anything bigger than a cottage hospital. If he has no place in the large institutions under natural conditions, ought we to provide an artificial environment in which he will thrive? Is the family doctor engaged on work of such national importance that he should be protected; or is free trade in medicine ultimately best for consumer and profession alike? These questions will have all sorts of answers in different minds, in different parts of the country, and in different circumstances. Even now we can find object-lessons in plenty if we look for them. There are already poor-law institutions which have pay-beds to which patients can be admitted under the care of their own doctor. There are others in which medical men are encouraged to follow their cases to the wards and consult with the superintendent and his assistants. Others again have coöpted local medical men as members of their consulting staffs; but here they are usually invited in some specialist capacity, and begin to lose their status as genuine general practitioners. This is the process which has given specialists to most of the big provincial towns during the past two generations, for where a man is attached to a large hospital as physician or surgeon he is apt insensibly to become a consultant—or at any rate a "consultoid." In this increasing specialisation some people see the salvation of the practitioner, but Lord MOYNIHAN (as is reported on p. 957) would have us beware of the tendency to put local doctors on the staffs of the new municipal hospitals unless they have the proper credentials. The hope of the medical profession, he says, is that the standards and ideals of the voluntary hospitals will guide and inspire the work of the old poor-law institutions under their new control, and it must be recognised that physicians and surgeons required for them do not at present exist. Lord MOYNIHAN evidently visualises a municipal hospital as developing gradually on the lines of the teaching hospitals, with no one on the staff who is not an F.R.C.S. or M.R.C.P. He agrees, however, that general practitioners should be given greater facilities for keeping in touch with their patients, and for following the practice of the hospitals so as to keep abreast of advances in medicine.

Possibly we shall have to admit that such facilities are the most that can be hoped for. Perhaps it is true that general practitioners when they demand admission to hospitals are asking for the lost opportunities of their youth, which they can never have again. We must beware of thinking that it does not matter what happens to the practitioner of to-day so long as we look after the training and chances of the practitioner of to-morrow. And we are not persuaded that it is impossible at once to bring the family doctor into much closer touch with hospital work. If the so-called salt of the profession is losing its savour, we do not believe it is beyond the wit of man to re-salt it.

◆

LATENT FRACTURES OF THE SPINE.

UNDER this title Médecin-Commandant M. CLAVELIN [1] writes of those minor or overlooked injuries of the vertebræ which have figured more largely in medical literature since the war. The number of violent injuries from explosions, falls of earth, and accidents to vehicles during the war, and the automobile accidents after it, have made this subject more important than it was even 20 years ago, while improvements in radiographic apparatus and technique have made early diagnosis possible where previously it was impracticable. No doubt it would be well if, as CLAVELIN suggests, we were to banish from our case-books such vague terms as contusion of the spine and muscular strain, for nearly always what is called contusion is really fracture, and muscular strain, however slight, involves rupture of muscle-fibres, which may be extensive enough to impair the muscular support of the spinal column. Not only may the bodies of the vertebræ be concerned in a crush fracture caused by excessive flexion, but any of the apophyses may suffer, and Clavelin has found that these latter lesions are accompanied by more acute and more localised pain than are compression and deformation of a vertebral body. The term "compression fracture" is perhaps not very happily chosen, for by fracture of a bone we usually understand a solution of continuity involving the division of one bone into two or more fragments, whereas a crush fracture of a vertebra consists not in a tearing apart but in a squeezing together of cancellous tissue and consequent alteration of shape of the bone affected. Any regions of the spine may be the site of a compression fracture, but the lumbar region is far more often affected than the cervical, and the dorsal least of all.

---

[1] Arch. de Méd. et de Pharm. Milit., 1929, xc., 439.

Unlike the classical fractures or fracture-dislocations of the spine, with their obvious and grave clinical signs and symptoms, these minor injuries have often been overlooked, especially when other and more grave injuries of the limbs and trunk have absorbed the attention of the surgeon immediately after the injury. But when these have been successfully treated disability may still remain, together with pain referable to the spinal column, which on careful radiographic examination may be found to be due to overlooked injuries. In other cases the original accident may have been comparatively slight; the symptoms may have been attributed to sprain and treated by too short a period of rest; after which instead of disappearing they may become worse, whereupon a more careful and more skilful radiographic examination reveals a definite lesion of bone. Clavelin has confined his observations to cases which he has seen for himself or which have been recorded in France. But the subject has not been neglected elsewhere and we may direct attention of students to the work of R. B. Osgood on compression fractures and to the discussion on minor injuries of the vertebræ which took place at a combined meeting of the Surgical and War Sections of the Royal Society of Medicine last January. On that occasion Group-Captain H. V. Wells[2] described typical cases of "latent" fracture—to use Clavelin's term—in which at or soon after the time of injury radiography showed nothing wrong with the spine, but which months later developed symptoms, and radiograms subsequently showed deformity of bone. The surgeons who spoke at that meeting for the most part thought that such deformity was due to morbid processes in the nature of an osteitis—coming on after the first radiogram was taken—a view which was stoutly challenged by at least one radiologist, who refused to accept it until more exact radiographic evidence was forthcoming. Clavelin, while discussing late-coming symptoms in minor injuries, does not deal with this syndrome, although he shows among the 24 figures which illustrate his paper, two of "spondylose traumatique" which bear evidence of arthritis deformans of the spine following on injury. However divergent the views held by various clinical observers, there is an unanimous belief in the necessity of skilful radiography (always in two planes), consequent early diagnosis, and early and adequate treatment. This last may be summed up in the Hiltonian prescriptions of physiological rest; but after this rest care must be taken to secure mobility if necessary by breaking down adhesions.

---

THE POSITION OF PSYCHO-ANALYSIS.

An attempt to place in perspective a book on "The Trauma of Birth," reviewed elsewhere in this issue, induces some reflections on the present position of psycho-analysis. The arguments of the author, as he himself states, are only possible and intelligible on the basis of the whole body of knowledge that has been gained psycho-analytically about the construction and functioning of our own psychical instrument. The assumption involved invites a general survey of the relation of psycho-analysis and medicine, since either this body of knowledge is a delusion, and books like this are waste paper, or we are ignoring a most important advance in the pathology and therapy of some of the commonest ills of mankind.

Freud's first announcements of his discoveries, over 30 years ago, were received with blank incredulity, and years passed before his ideas began to receive attention, even from a few. Now they are being to a greater or less degree confirmed by an ever-increasing number of practical workers, and they influence our conceptions of neurotic disorders more than is generally recognised. Recently a committee of the British Medical Association was appointed to inquire whether the practice of the specialty is immoral or dangerous; the fact that propriety and usefulness of this sort had been publicly questioned justified this unique inquiry, which resulted in the acquittal of psycho-analysts of evil practice. What this new method of approach can offer to medicine is, however, a question we seem in no hurry to consider. The fact that, if confirmed, it will mark an epoch in the growth of knowledge escapes the observation of many who may thus be losing the opportunity of watching history in the making. An active psycho-analytical organisation certainly coördinates work in different countries, and has published a large mass of observations, theories, and speculations, resulting from work that is evidently laborious and painstaking; but this organisation stands aloof from the general body of medical or scientific thought, and a glance at the history of the psycho-analytic movement suggests that in this aloofness Otto Rank might see the results of a difficult delivery and a stormy childhood. As a possible bridge across the gap we find individual practitioners who make use of analytical teachings in the treatment of psychoneurotic patients, but these seem to receive little academic encouragement and are denied, or deny for themselves, the title of psycho-analyst. The situation is without precedent. In the controversies associated with the names of Darwin and Lister the opponents came to grips in the scientific arena and reached conclusions. Although the acceptance of evolutionary theory was delayed by emotional opposition, and finally became a matter of gradual absorption, yet in the stormiest times its exponents were not driven from the scientific fold. The unanswerable virulence that expressed itself in our journals some twelve years ago is happily a thing of the past. Yet in London to-day few young men on the threshold of an academic career in medicine would dare to give open adherence to psycho-analytical principles, or even to investigate them practically in a scientific spirit.

For this state of affairs it is futile to ascribe blame in any particular quarter. The historian sees in such situations the play of forces inherent to human nature, and the cases of Darwin and Freud are alike if only because in each of them the world's peace of mind was apparently in danger and man's satisfaction with himself was shaken. The intrinsic qualities of the processes revealed by analysis are held by his followers to be responsible for the determined rejection of Freud's discoveries, and they rightly plead that to make them answerable for these qualities is the negation of science. We may eventually come to acknowledge a debt to those workers who, as we have seen, are content for the present to be isolated from the general current of medical thought.

By that time we shall have answered the questions that arise from the reading of "The Trauma of Birth"—do these things happen, and if so, what is their import to medicine? The nature of the answer to these questions cannot be prophesied. The trouble of investigating psychology from this new aspect should not be minimised or attributed only to its unwelcome message; its exponents are still unable to agree on even the fundamental tenets of the faith. Few of them follow Freud in all his teachings, and it is likely that the pattern ultimately to be woven will be made from many designs which at present seem to clash with one another. Our plea is that in the medical schools some equipment should be given to the student to enable him to follow the developments of Freud's ideas, and eventually to assimilate those which will help him to understand his patients.

Annotations.

"Ne quid nimis."

PRINCIPLES OF PUBLIC HEALTH DEVELOPMENT.

An ordinary industry, as Dr. J. J. Buchan pointed out in his presidential address to the Society of Medical Officers of Health on Friday last, is constantly reviewing its organisation and making any outlay necessary to improve efficiency, maintain position, increase profits, and diminish expenses. Yet, although the only real capital of the State is the health of its people, this vigorous progressive acumen is seldom seen in the department of public health. The public health is a good business proposition, for it has done more in the past to increase capital and diminish expenses than the most successful industrial venture on record. Despite a chaos of patchwork legislation and great inherent difficulties, the rate of progress in recent years calls, as Dr. Buchan pointed out, for some satisfaction, but he laid down certain principles for the future which should ensure a continuance and amplification of the success already attained. We are still far short of making full use of the knowledge we already have and still more wanting in facilities for research. Every up-to-date industrial concern maintains a research institute; surely the State should not leave the great bulk of research work in health to the self-sacrificing labour of the few and the vicarious generosity of the well-intentioned. Dr. Buchan's first principle was that the protection and improvement of the health of the people should be regarded by the State as an end worthy in itself. Too often in the past public health has crept in behind the skirts of some other work, as, for instance, the public health services under the poor-law, which were no more than a side-line in the relief of destitution. This has been set right, but similar examples still abound, notably in factory legislation. "Despite a succession of statutes and a multitude of orders," said Dr. Buchan, "factory legislation has continuously failed to meet fully the real health needs of the whole body of the employed . . . only some six millions out of sixteen and a half millions of occupied persons come under the Factory Act." He refused, however, to regard the health of the worker as a labour problem to be solved by codification of industrial laws; the health problem is fundamental and the health of the employed must be brought under the Ministry of Health and not under the Home Office. His second principle was that the people cannot be sectionalised; evil conditions in one class, at one age, or in one set of circumstances have comparable evil conditions in very different departments. Health in pregnancy, for instance, must be viewed in relationship to the conditions before and after pregnancy, and the more deeply we inquire into the health of school-children the further do we travel from the school. The third principle was that a central unification and reorganisation of health effort is not in itself sufficient unless it is accompanied by a similar unification and reorganisation at the points of administration. Health work in this country has always suffered, he maintained, from a lack of well-ordered and well-arranged local government areas. The State should permit no consideration of local history, pride, prejudice, or precedent to stand in the way of securing competent machinery of local administration. His final principle was the complete freedom of expression of the professional health officer within his own sphere. To be of any service he must be absolutely free to express his opinion on any matter of health, whether it be lead poisoning among painters or the exclusion of school contacts in infectious disease. Any control of this expression of opinion must come from within the public health service itself, and not from administrators who have not the knowledge to control opinion on such subjects. "In no other kind of public activity," concluded Dr. Buchan, "is there such a solidarity of interest for all the people, and in none is their coöperation and help more desirable." This coöperation depends almost entirely upon the better education of the great mass of the people in matters of health, and for this education the public health officer must rely to a very large extent on the general practitioner, who has it in his power to take the knowledge of hygienic principles into the homes and hearts of the people.

PERNICIOUS ANÆMIA WHICH RESISTS LIVER TREATMENT.

Are there any cases of pernicious anæmia which will not respond to liver? The general experience both here and in America seems to be that there are not; but Dr. P. Emil-Weil now publishes[1] three cases diagnosed as pernicious anæmia which got no better under modern treatment. The patients all showed severe anæmia with a high colour-index and some leucopenia; in one the spleen is said to have been enlarged. Liver was given, both as whole gland and in the form of extracts; this treatment was supplemented by frequent transfusions of blood; yet no improvement followed, and all the patients died after illnesses of some months. The question naturally arises whether the diagnosis was correct. We have at present three criteria of pernicious anæmia—namely, achlorhydria, hæmolysis, and an increase in the mean size of the red cells. A high colour-index is indirect evidence of the last of these, and it was observed in Emil-Weil's three cases. But he gives no information about the other two signs, and failing this it would be rash to amend the aphorism that anæmia which will not respond to liver is not pernicious anæmia.

JUVENILE RHEUMATISM IN MARYLEBONE.

The St. Marylebone Children's Rheumatism Supervisory Centre was instituted at the General Dispensary in 1926, and has now published its first report with an analysis of the first 100 cases. An attempt is being made to combine into a simultaneous objective a clinical inquiry into the prevention of heart disease and a laboratory investigation into the nature of the rheumatism of childhood. The clothing was good in 71 per cent., fair in 23 per cent., and bad in 6 per cent. The family income was adequate in 79 and inadequate in 21. The housing was good in 23, overcrowded in 32, damp in 8 only, insanitary in 11, and inadequately light in 9. The clinical analysis shows the family and personal history, age, previous infections, early symptoms and state of nutrition, teeth, and blood pressure. The biochemical work includes hæmatological and chemical examination of blood, urine, and fæces, and certain abnormalities have been found with some consistency. In 75 of the children focal sepsis could be excluded, and the constitutional findings in the remaining 25 provided presumptive evidence of a rheumatic diathesis with a secondary superadded septic factor. Cardiac involvement was found in all the children (60) who exhibited a lowered alkaline reserve. Cases which showed a deviation of the acid-base balance to the alkaline side were eventually classified as non-rheumatic, both on clinical and on biochemical grounds. Phosphate and sulphate excretion was abnormal in more than half the cases, and the aromatic sulphate fraction was increased in 30. Calcium excretion was low in 65, and 70 showed an abnormal carbon-nitrogen ratio. No consistent variations from normal were found in the fæces except for an excessive loss of calcium in 40. Some of these findings are suggestive, but the director, Dr. Halls Dally, rightly declines to draw conclusions at this early stage of the work.

DUTCH MENTAL HOSPITALS.

OF the subcommittees formed by the Royal Medico-Psychological Association there is one which organises study tours and post-graduate education in mental disorder. Just a year ago a party visited the mental hospitals of Holland, and an account of the tour has now been published in pamphlet form.[1] The Dutch Lunacy Law differs from our own in a few respects. Until 1906 a patient could only be received into a mental institution on the certificate of an independent medical practitioner, and the petition of a relative or of the Public Prosecutor in lieu. Any building where more than two insane persons were treated was legally an asylum, but in 1906 the law was amended so that patients could be received in a university clinic without labelling the building as an asylum. Thus patients can now be taken into these institutions or into separate blocks in mental hospitals, called "open wards," without the formality of certification or periodic statutory reports. The visitors last year found that 20 per cent. of the inmates of mental wards had been admitted without any kind of certification. Many of them were obviously non-volitional, and isolation, seclusion, or continuous bath treatment were ordered for them, irrespective of the basis of admission. There is no legal provision for single care or for the disposal of the income of well-to-do patients. One doctor to every 175 patients is required in new hospitals. The medical director is the chief officer, except in Roman Catholic institutions, where the Prior exercises general control. The State issues a diploma in mental nursing after three years' training and examination. The proportion of nurses to patients is about double that found in Britain, but Holland experiences the same difficulty as we do in securing suitable applicants. Assistant nurses are paid from £45 to £60, and nurses holding the diploma £146 to £160 per annum, and the working week varies from 48 to 60 hours. Female nursing of male patients is commoner there than in this country.

Perhaps the most striking feature of the Dutch mental hospital is the application of Dr. Simon's occupational therapy, which was devised with a particular view to improving the condition of restless, destructive, or filthy patients in turbulent wards. It is based on pedagogic principles. Four or five patients are put together in a little alcove, and stillness and silence are enjoined. When a new patient joins the group the atmosphere of quiet industry has a strong influence. Any patient who becomes noisy is removed to a single room for a period varying from ten minutes to an hour, as a penalty. The work on which the patients are employed includes raffia, tearing rags or coir, untying knots in string, rolling string into balls, envelope-making, cleaning letters off three-ply wood tea-chests, rudimentary knitting, rug- and mat-making, tobacco-leaf stripping, brick trimming, tile-making, and cleaning labels. The articles made by more advanced patients display much ingenuity and activity with every variety of handicraft, but even the least intelligent can produce wire paper clips or firelighters made of rolled shavings. Weekly payments are made in recognition of good behaviour and regular work, and to promote self-esteem. On July 1st, 1928—a day taken at random—1273 out of 1420 patients at Santpoort were doing some kind of work; of the remainder, 122 were too old or ill, and only 25 were unoccupied for mental reasons. Dr. van der Scheer, of Santpoort, maintains that turbulent behaviour is not a part of the psychosis, but arises secondarily from loss of educational and environmental influences; he believes that noisy wards will follow mechanical restraint and dark cells into oblivion. Padded rooms are unknown in Holland, their place being taken by continuous baths in which the patient is fixed by a wooden or canvas lid with a padded opening for the neck. Even this restraint is now very little used. A method frequently employed for controlling acutely excited or depressed patients is Kläsi's continuous sleep. Somnifen is given orally or by intramuscular injection twice a day, and the patient is kept absolutely quiet. Manic-depressives may be kept under the drug for a fortnight; dementia præcox patients for a few days. As the somnolence begins to pass off the patient is exercised by two nurses and started on manual occupation, so that by the time he is fully awake again he finds himself engaged in some quiet employment. Sometimes opium is given instead of somnifen.

There is an interesting after-care service in Rotterdam. A special practitioner living in the town is selected as outdoor service doctor; he attends the hospital weekly for a whole day, and so is well acquainted with hospital routine and problems. He gets to know the patients before they leave, and his services are offered to them for after-care and seldom refused. He inspects the environment to which they are returning, and thereafter visits as often as seems desirable. A consulting clinic has arisen out of this service but was not the primary element of it: the home visitation is stressed as the most important and illuminating part of after-care. The service is in close contact with the local welfare society. Since its inauguration three years ago the insanity figures for Rotterdam have decreased, although the population has soared, and other cities in Holland show no corresponding decrease. Thoroughness was the quality in all this work which consistently impressed the visitors; therapeutic measures and laboratory research alike are pursued in Holland with energy and application.

The committee is doing a great service to European psychiatry in linking up the work of different countries by these study tours, and it was a happy corollary of the visit to publish this account for those who were unable to take part.

SCLEROSING INJECTIONS IN THE TREATMENT OF HERNIA.

SCLEROSING injections in the treatment of varicose veins have become deservedly popular; their effective superiority to excision has been proved beyond dispute. It is not surprising therefore that investigators have sought to adapt similar methods to the treatment of other conditions, such as inguinal hernia. It is curious to what extent the sequence of events corresponds. Injections for the cure of varicose veins were employed about the middle of last century, but were discarded as dangerous largely because the fluids used were unsuitable. Now Dr. J. S. K. Hall[1] reminds us that Velpeau, in 1835, was the first to think of an injection method for the cure of hernia, and actually put his plan into practice, using an iodine solution as the fluid. Several other surgeons followed his lead and good results were recorded. For some reason, probably because the fluids used were too irritating, the method fell into disuse and, according to Dr. Hall, has only been resuscitated by the work of Dr. Pina Mestre, a Spanish physician, who published his experiences in 1927. He and his associates claim to have treated more than 8000 cases of hernia. Almost without exception the inguinal canal was obliterated in 10–15 days. The success recorded appears to be due to the discovery of a non-irritating and effective liquid. Like that used in the treatment of varicose veins, the method is an ambulatory one. The injection is composed of a mixture of the alcoholic extracts of several astringent plants, of which the most important seems to be rhatany. The hernia is first reduced and an injection made every day in the region of the external abdominal ring. An indurated mass appears in a day or two which effectively blocks the inguinal canal. Precise details of the formula are not given by Dr. Hall, nor is it clear whether the injection is made within the lumen of the sac or around it. Various objections are likely to arise in the mind of a critical surgeon reading this account. He may well ask what will happen if inadvertently the injection is made intraperitoneally, whether the coils of intestine in the neighbourhood of the internal ring become adherent in this situation, whether or not thrombosis may sometimes be caused in the pampiniform plexus, and whether, in infants, to whom the method is said to be applicable, any damage is done to the delicate vas deferens. None of these questions is touched upon, but it is scarcely likely that 8000 patients would have submitted to the treatment had complications been frequent. The method, whilst in principle it lacks precision and does not therefore attract the surgeon, appears worthy of consideration; and further investigation is desirable because any effective ambulatory treatment of this common abnormality would be a boon to countless sufferers.

LATER BREAKFASTS IN HOSPITALS.

EVERY profession has its critics amongst what it chooses to call the lay public, and close association with any profession is usually sufficient to show that there are very good reasons behind what the outsider is often inclined to consider an abuse. It has long been a matter of astonishment and indignation amongst a section of the public that the sick, when they are admitted to a hospital or nursing home, find themselves roused from their sleep many hours before the time at which they would be woken up in their own homes. Doctors and nurses know that the cleaning of the wards and the washing of many patients takes a considerable time, that enemata and douchings and dressings often have to be carried out at an early hour, that four-hourly medicines must be given by the clock, and that in fact the hours before 10 A.M. are extremely busy ones for nurses, whose duty it is to have their patients suitably prepared for the visit of the surgeon or physician. To harmonise these interests with the rest which is often the primary therapeutic need of the patient is almost an impossible task. The layman who is inclined to grumble when two nurses have to be installed into his house to look after a sick patient is often slow to comprehend that if all these morning duties were to be piled upon one nurse she would be quickly worn out. Twelve hours is the utmost a nurse can be asked to work, but in private it can be arranged for the change of duty to take place at the hour, be it 8, 9, or even 10, when an equitable distribution of hard work can be made. But in hospital such adjustments are not so easy, since the needs of individual patients vary. It is therefore a satisfaction to learn that the authorities of the Middlesex Hospital have been able to reorganise the work of the hospital on lines which will allow the patients to rest undisturbed until 7 A.M., when breakfast will be served. We understand that in order to introduce this reform—in which the matron, sisters, and nursing staff are eagerly and loyally coöperating—it has been necessary to bring the day nursing staff on duty at an earlier hour and that the visits of the resident and other medical officers and presumably of the students are to be postponed until after 10 A.M. The change is introduced at the moment when the new west wing of the hospital is being occupied, and the authorities believe that their example will be followed by hospitals throughout Great Britain. As much depends upon the interpretation of such a rule as upon its actual wording. If such urgent treatment as is required in the early hours for individual patients is administered without clatter, if ward maids are excluded till after breakfast, and the routine cleaning of floor and lockers is also postponed, the concession will result in securing an extra hour of rest to the patients, possibly even more. In many hospitals it is the custom to serve breakfast at 6 A.M., the active patients being provided with hot water only after the meal, while the helpless ones are washed before it; if there are many of these the process must be lengthy and some at least must be roused uncomfortably early. Any attempt to make the hospital more like the home deserves praise. A later breakfast is one way. Another is to sacrifice the appearance of the ward to the idiosyncrasies of the patient; to allow him to smoke and receive visitors during convalescence, and to accept from his friends fruit and other delicacies which the hospital cannot provide; and finally, to ensure that his friends can obtain not only news of his progress but messages of his wants on the telephone. The Middlesex Hospital is one of those with a reputation for consideration as well as good treatment, and has given new proof that this reputation is deserved.

CHLOROTIC ANÆMIA IN THE MIDDLE-AGED.

A LOW colour-index of the blood associated with virginity in young females used to be regarded as an indication for the administration of iron in large doses or the encouragement of early marriage, either remedy being effective. Chlorosis is now so rarely seen that there must be those among students and medical men of fairly recent standing who wonder whether the whole syndrome of green sickness was not a figment of the imagination of the earlier clinicians. No one, however, who was walking the hospitals 20 years ago will deny that the condition existed. The reasons for its disappearance afford much subject for speculation; increase in the therapeutic use of iron and changes in the dress and normal activities, customs, and pursuits of girls have both been suggested. While typical chlorosis has practically disappeared, however, it is becoming evident that there are other types of anæmia associated with a low colour-index still to be reckoned with. A well-recognised type is that associated with hypofunction of the thyroid; a further type occurring in adult females leading a normal sexual life has been closely studied by Dr. Grieg Altschuller[1] at the Medical Clinic of the University of Prague. In the particular case described by this author there was moderate diminution of the red cells with profound depression of the hæmoglobin percentage and consequently a very low colour-index. The basal metabolism rate was lowered, but the condition made no response to thyroid medication and could therefore be removed from the thyreogenic class. The exhibition of reduced iron in large doses brought about a speedy improvement in the blood picture; when the iron was dropped the anæmia returned, but was again abolished by its administration. In fact, the condition behaved like a case of chlorosis, but differed from it in occurring in a widowed woman of 45, who had borne several children, and in the absence of the peculiar aspect of chlorosis. In considering the case Altschuller points out that hæmatopoiesis may be considered under three heads—the production of the young red cells, their saturation with hæmoglobin, and their liberation into the blood stream. In cases of the sort described he sees a disturbance of the second step, which is also that affected in the chlorotic diathesis. The fact that in Altschuller's own case the subjective symptoms of headaches, lassitude, and fatigue disappeared within a few days after the exhibition of iron, before any change had become detectable in the blood picture, he takes as confirmation of the view of Morawitz that the action of iron is not confined to the blood-forming system but extends to other organs, including those of internal secretion.

SEWAGE ANALYSIS.

THE Committee appointed to discuss the question of technique in carrying out chemical analyses of sewage and sewage effluents has now brought in its report,[1] which is designed to assist those who are engaged in testing the purity of effluents and of rivers. Two sentences in the report sum up well the two points of view held by analysts on the question of standard methods :—

> "A reasonable measure of uniformity is desirable in the methods to be followed in testing the quality of sewage liquors, before and after their purification, and also in the statement of analytical results. Without this it is difficult to be assured that the same standards are being applied or that really comparable results are being obtained. Reasonable uniformity is essential if a common language is to be spoken."
>
> "This search for some measure of uniformity is not intended in any way as a break on initiative, upon which progress in methods depends. It should not, however, be difficult to secure both objects, reasonable uniformity and full initiative."

When the thing to be determined is a definite chemical entity the real chemist will no doubt prefer to choose his method to suit the case; it is only the man who is afraid to exercise his judgment who will willingly let it be bound. In the case of sewage, however, some measure of standardisation, both of methods of analysis and of setting out the results obtained, is desirable. For sewage is a very complex mixture of unstable compounds, containing within itself living agents which continually work changes and modify its composition from hour to hour. Ammonia, chlorine (or rather chlor-ions), and total nitrogen are well-defined chemical individuals; yet in sewage and effluents ammonia is readily formed by the very reagents or processes used, through hydrolysis of amines and the like, while the total nitrogen content of a liquid containing 0·01 per cent. or less is not determinable with the same ease as it is in, say, a sample of bone-meal. The conception of "albuminoid ammonia" which we owe to that brilliant but erratic genius Alfred Wanklyn is another useful label—not to be dignified with the name of entity—which is only valuable if it is applied in the same rigid manner by all whose results are to be compared. This is in brief the case for standard methods of sewage analysis.

The personnel of the Committee and the fact that Dr. George McGowan was mainly responsible for details is a guarantee that the methods are sound. Criticism, if any, will be directed to a degree of precision which may be unnecessarily high and involve an undue expenditure of time. The report opens with the question of sampling, for the most careful analysis in the world would have no value, except as a laboratory exercise, unless made on a sample which really represents something definite. A consideration of the way in which sewage is produced, the daily incidence of the morning wash or bath, other matters of personal hygiene, washing-up, street watering, and the regular operations of industry, the weekly round of washing days, washing-down after brewing and similar intermittent operations, with irregularities of rainfall and secular changes due to the seasons—all these affect the composition of sewage. No shorter interval than a day can be regarded as yielding a representative sample, and this day should be one on which there is little or no rain. Samples should, whenever possible, be analysed within 24 hours of collection, the time elapsing being stated. Results of analysing the same sample one, two, three, and six days after collection are given in an appendix; although the total nitrogen remained constant, the proportion of ammonia went up at the expense of organic nitrogen—in other words, chemical simplification was going on. In the illustration given, however, the variations of solid content suggest that the samples were not at the beginning quite identical, as the non-volatile matter varied; calcium carbonate may have separated out owing to the increasing alkalinity of the liquid. The increase of oxygen immediately absorbed from permanganate showed that unstable organic matter was increasing, while a decrease of that absorbed in four hours seems to indicate that oxidation had gone on, reducing the total oxidisable matter. Turning to the methods themselves, it may be remarked that Crum's mercury-sulphuric acid process for nitrates and nitrites has the advantage of being positive and specific, although rather troublesome; *it is useful* in cases where the presence of these compounds is a priori improbable and it is desired to verify the findings of a differential method. The mysterious entity known as "X nitrogen" is given its proper significance, which is merely the difference between the real organic nitrogen and that indefinite portion of it which is yielded by the Wanklyn process as "albuminoid nitrogen." The Committee recommends that analyses should, as a rule, include estimations of suspended matter, chlorides, free saline and albuminoid ammonia, oxygen absorbed from an acid solution of permanganate, and, in addition, in the case of purified effluents, nitrates, nitrites, and the Royal Commission test for oxygen taken up from aerated tap water. It is important to distinguish between the last-named test and the permanganate test for oxygen absorbed, the results of which bear no simple relationship to the Royal Commission test.

The report should prove of value not only to analysts but to medical officers of health, engineers, managers of sewage disposal works, and other officials of local authorities on whom falls the burden of sewage disposal. What this burden amounts to is well indicated in Mr. A. J. Martin's recent Chadwick lectures which are summarised on p. 961.

INFANTILE MORTALITY IN KENSINGTON.

To people who do not live there the name of Kensington suggests the last resting-place of smug respectability, the essence of organised drapery, beautiful gardens, or dismal slums. Few envisage the borough as a whole. It is in fact a long, narrow slice of the County of London, shaped like the popular, if unfashionable, Russian boot. Its heel extends south of the old exhibition grounds at Earl's Court, to take in the West London (Brompton) cemetery. Its pointed toe touches Piccadilly at Knightsbridge, and its rucked leg includes no part of Kensington Gardens, but, on the other hand, many of the squares, such as Pembridge-square, usually associated with Bayswater. The whole of Holland Park and Campden Hill, and the more dilapidated areas of Notting Hill are included in the borough, its northern boundary at the top of the boot being another cemetery, Kensal Rise. Even a casual survey of this medley of social conditions shows how perplexing would be the problem of investigating any statistical anomaly in the public health of the borough if undertaken by one unfamiliar with the distinctions which fashion has drawn between adjoining districts. It is therefore from within the borough that we must seek light. Fortunately, a group of the doctors practising in the borough are concerning themselves with the welfare of the community, as well as with the health of individuals. The North Kensington Medical Society, which has already shown signs of an active interest in the medico-social questions of the day, met on Oct. 8th at 85, Colville-road, W., to discuss with each other, and with Dr. J. Fenton, medical officer of health, the cause of the large increase in infantile mortality in 1928. The population of Kensington is 176,000, and the infantile mortality-rate rose from 61 in 1926 to 67 in 1927, and to 85 in 1928; the borough thus shares with Paddington the ignominy of losing 18 more infants under a year old for every 1000 births than the average London district.

---

[1] Ministry of Health: Methods of Chemical Analysis as Applied to Sewage and Sewage Effluents. H.M. Stationery Office. 2s. 6d.

The reasons suggested by the speakers for this high mortality varied widely. Dr. E. M. Reece attributed it largely to overcrowding, poverty, and to lack of open spaces. Dr. A. K. Gibson and Dr. A. K. Barrett thought that maternal care must be at fault, and Dr. M. Hellier agreed that many of the mothers went out to work long before the child was fit to be left. Dr. W. C. Robinson spoke of the possible correlation between high infantile mortality and large families. Dr. A. B. Pastel proposed the separation of children suffering from tuberculosis, and the provision of an increased number of qualified midwives, as remedies which might be efficacious. Dr. D. M. Scrimgeour, Dr. R. H. Draper, and Dr. E. Lowlor emphasised the special dangers to which illegitimate and unwanted children were exposed, while Dr. M. W. Geffen had found illegitimate children to be well cared for and healthy. Dr. Christine Murrell and Dr. H. Sanguinetti believed that congenital syphilis accounted for more deaths than was generally admitted, but Dr. G. Slot agreed with Dr. Fenton that the syphilitic mother was rare. Dr. Fenton pointed out that there seemed to be no advantage from the point of view of infantile mortality in a rich population; moreover, since 32·8 per cent. of the deaths took place during the first four weeks of life housing conditions could hardly be incriminated. The closure of basements for residential purposes had its dangers, since unoccupied basements might collect vermin, and become more of a menace than occupied ones. Dr. Fenton concluded by welcoming the coöperation of doctors practising in his district. The outcome of the discussion was the passing of a resolution deploring the high infant mortality-rate in the borough, and proposing further investigation of deaths under one year of age. To this end it was suggested that three members of the Society should confer with the medical officer of health in order to arrange a scheme, or to make further use of existing methods of inquiry.

MEDICAL SCIENCE IN THE FIFTEENTH CENTURY.

A VOLUME[1] consisting chiefly of special studies of the philosophy of the fifteenth century, based in large measure upon manuscripts and unpublished material, makes it clear that the contributions made to medicine and surgery during the fourteenth and fifteenth centuries have been much undervalued. Disparaging generalisations at the expense of the Middle Ages should now be repeated only by those who refuse to give up any catchword or prejudice that was instilled into their minds in childhood. In the first chapter, which is perhaps the most interesting of all, the author introduces the reader to the scientific and other thought of the fifteenth century and aims at giving him some notion of what has been accomplished and what remains to be done in the way of historical investigation of this period. His own studies are recorded in the following chapters and in the appendix which occupies 100 pages. These concern medicine and the law, astronomy, mathematics, and speculative, moral, natural, and political philosophy. There are ten illustrations of manuscripts and diagrams, and the book contains not only a general index, but also an index of the manuscripts referred to. Publication has been assisted by a grant from the Dunning bequest left to Columbia University for the encouragement of historical studies. The inventiveness of the Middle Ages continued to manifest itself in the fourteenth and fifteenth centuries, and in the opinion o fthe author printing is about the only invention of this period thus far adequately studied. During the fourteenth century systematic dissection of the human body was practised for purposes of instruction; and advance was made in measures against infection as a source of disease, and long before the close of the fifteenth century mercury salve was used in the treatment of syphilis. The work of Henry de Mandeville reveals him as a pioneer of antiseptic surgery at the beginning of the fourteenth century, but perhaps the most striking instance of surgical achievement cited is a passage from Bartolommeo Fazio's *De viris illustribus* written in 1456. Mention is there made of the Brancas father and son, Sicilian surgeons, of whom the father was a direct forerunner of Gasparo Tagliacozzi, being—

> "the inventor of an admirable and almost incredible process. For he thought out a way to re-form and complete dissected and mutilated noses, and accomplished all this with wonderful art. Moreover, Antony, his son, added not a little to the beautiful invention of his father. For he devised a process by which mutilated lips and ears as well as noses could be repaired. And while the father had cut skin to piece out the nose from the face of the mutilated person, he took it from the arm so that no facial deformity resulted therefrom. And he inserted the remains of the mutilated nose and bound them up so tightly that the mutilated person could not even move his head. After 15 or 20 days he would little by little cut open the bit of flesh that adhered to the nose and re-form it into nostrils with such skill that the eye could scarcely detect where it had been joined on, and all facial deformity was completely removed. He healed many wounds which it seemed that no resource of medical art could heal."

During the fifteenth century, as in more recent times, the relative merits of law and medicine were occasionally the subject of debate. In course of a dispute of this kind Salutari pointed out that whichever profession is the nobler in origin, it is generally recognised that the lawyers occupy a higher social position. Carlo states that they are called lords and their wives are called ladies, whereas medical men are simply designated as masters, a name common to all vile craftsmen, while their wives receive no title whatever. To this Niccolo can only retort that professors of theology, the supreme science, are also called masters, and that the peasant sometimes calls his donkey "Lord." It would be interesting to hear a discussion on this subject 400 years later; the Medico-Legal Society might consider its inclusion in their programme.

THE MEDICAL REGISTER OF THE IRISH FREE STATE.

"THE Medical Register of Saorstát Éireann" appeared for the first time last week. It is the official register of medical practitioners in the Irish Free State, published by direction of the Medical Registration Council of Saorstát Éireann as ordered by the Medical Practitioners Act, 1927. The volume consists of XXII and 119 pages, and is sold at 10s. Besides the Register proper, it has a list of the members of the Registration Council, a copy of the Medical Practitioners Act, 1927, extracts from the Dentists Act, 1928, and tables of the various qualifications which are registrable. The Register contains the names and addresses of 4130 practitioners, of which 4085 were on the Register on the date of its establishment on May 26th, 1928, and 58 were added between that date and Dec. 31st, 1928. Twenty-five names were removed on account of death during that period. The arrangement of the Medical Register follows in its general lines that of the General Medical Register, but contains two additional columns, one to indicate the channel by which admission in the Register has been gained (General Register, Colonial, Foreign or Direct), and one for a serial number. The printing and format of the volume are attractive, and every care appears to have been taken to avoid errors.

---

[1] Science and Thought in the Fifteenth Century. By Lynn Thorndike. New York: Columbia University Press. 1929. Pp. 387. 24s.

not stultify that diagnosis, if there is a history of halogen medication and clinical signs are sufficiently definite, for it is quite probable that the failure of the excretory mechanism is the cause of the rash.

Blood counts are sometimes indispensable adjuncts to correct diagnosis. Thus it should not be forgotten that pruritus, or an erythematous rash of wide distribution, may be the first symptom of leukæmia. Nearly all long-standing itching eruptions are associated with eosinophilia, and a pronounced excess is characteristic in dermatitis herpetiformis, pemphigus, and solar eruptions.

Of late years *X rays* have continued to play a not unimportant part in the determination of the focal sites of obscure chronic diseases. In dermatology their chief function has been in connexion with apical sepsis of the teeth, and such conditions as erythema multiforme, urticaria, and purpura have been cured or greatly benefited as a result of well-considered extractions. The interpretation of the radiograms is often a matter of difficulty. Cases are known in which the removal of condemned teeth had no effect on the cutaneous symptoms, and conversely, not a few in which, although the photographs were apparently negative, the extraction of teeth known to be dead and therefore septic foreign bodies, was followed by immediate and permanent benefit to the patient. Every case has to be judged on its own merits. Undoubtedly the dentist is a better tribunal than the physician, for he has other means of deciding the issue besides X rays. The final decision should rest with the patient, and neither dental nor medical persuasion should be too cogent.

HENRY G. SEMON, M.D., M.R.C.P.,
Physician for Diseases of the Skin, Royal Northern Hospital.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. N. A. H. Barlow to be Surg. Comdr.

THE PANEL CONFERENCE.

PRIVATE PRACTICE AND THE HOSPITALS.

ON Oct. 24th the representatives of local medical and panel committees met in London for their annual conference. Dr. E. K. LE FLEMING presided for the fifth year in succession, and the meeting was held as usual in the British Medical Association's house in Tavistock-square.

Medical Certification: Disciplinary Procedure.

Last year's conference was largely devoted to discussing the reasons why claims for sickness benefit have lately increased. While protests were made against the allegation that panel practitioners in general have become careless in issuing certificates, it was agreed that a certain amount of laxity had always existed, and provisional approval was given to certain measures which would expose gross abuse of the sickness funds. The Insurance Acts Committee (I.A.C.) and the Ministry of Health have since been considering what action should be taken against practitioners who are thought to have made out certificates improperly, and the proposed machinery for dealing with such cases was explained to the conference last week. The Minister's first step is to refer the case to the panel committee (or to a committee formed for several counties) which will hear the charge and the evidence on both sides, and report whether the practitioner has failed to exercise due care in certification, and (if so) to what extent and how gravely. It will make recommendations to the Minister, and at the same time will furnish the defendant practitioner with a copy of its report and conclusions. If either the Minister or the practitioner is dissatisfied with the findings, the case will be referred to an appeal committee, which is likely to consist of three medical practitioners who are not officers of the Ministry. After considering the findings and recommendations of the panel committee, and (in case of appeal) of the appeal committee, the Minister will state what action he deems appropriate. The practitioner may then make further representations against the decision, and if he does not accept it the various findings and recommendations will be referred to an advisory committee composed of representatives of insurance practitioners, approved societies, and insurance committees.

In commending these plans to the conference, Dr. H. G. DAIN (chairman of the I.A.C.) said it was essential that the body which first heard the complaint should be professional, and that it should be able to make its representations direct to the Minister. The present system allowed of public criticism and press reports which caused regrettable misconceptions. On the other hand, the approved societies would not consent to any arrangement from which they were altogether excluded, and it was outside the province of the conference to tell the Minister what advice he should procure after receiving reports on the facts.

The constitution of the Minister's advisory committee provoked a discussion, in which Dr. C. F. T. SCOTT said it was wrong that professional matters should be judged by a predominantly lay committee. Like Dr. W. LOCK he held it contrary to the spirit of British justice that the Minister, an interested party, should appoint the tribunal to decide the issue. Dr. L. J. PICTON, for Cheshire, proposed that the advisory committee should be replaced by an independent barrister, sitting with a medical assessor, who would hear all parties and form an unbiased opinion. Panel practitioners, he said, had surrendered their claims to an appeal to the High Court because they were assured that cases would be referred to a professional committee—consisting of three medical officers of the Ministry and three of their own representatives. This committee was now to be disbanded in favour of a partisan body on which approved societies and insurance committees would have a majority.

Dr. DAIN replied that these criticisms of the scheme arose from misapprehension. There would be no interposition by laymen until the questions of fact had been decided. The advisory committee would not be able to re-try the case; it was not a tribunal or a court of appeal, it would not hear evidence or advocates, and its duty would merely be to advise what action should be taken on the proven facts. This meant that the approved societies and insurance committees were out out of the proceedings till after the case was judged, and this was as far as the Minister would go. If the approved societies were not allowed to say something to the Minister at some stage the scheme would fall through, and this would be a pity, because everyone was anxious to put a stop to the action of those few practitioners whose lax certification was prejudicing the position of their colleagues. Dr. E. R. FOTHERGILL called this "sentiment," and pressed for amendment of the draft regulations. But the conference did not accept his view, and ultimately gave its approval to the procedure proposed by the Ministry.

Dr. G. J. B. CANDLER-HOPE, for the North Riding, suggested that in cases of excessive certification the fine for a first offence should not exceed £5, and complained that the amounts withheld by the Ministry often bore no relation to the recommendations of the medical service subcommittees. No law was passed without stating a maximal penalty for its infringement, and he wanted to introduce the principle that breach of the regulations should be met by payment of a fixed sum. Dr. DAIN, however, took the view that each case should be decided on its merits. A maximum was undesirable because it tended to become a minimum, and it was not the least bit true to say that these things were decided at the mere whim of the Minister. "We have got rid of all that business now," said Dr. Dain, "and we are satisfied that the machinery introduced a year or two ago is working extremely well."—The North Riding amendment was lost.

Dr. J. NELSON, for Kingston-upon-Hull, proposed "that the statistics relating to the issue of certificates by doctors in each area should be circulated to panel committees as in the case of prescribing certificates." This was accepted by the conference on the ground that it might be useful to a practitioner to know how his issue of certificates compared with the average for the same district.

Reference of Cases to the R.M.O.

Dr. DAIN reported that approved societies were finding that the money available for referring cases to regional medical officers was all used up—(cheers). Surprising as it might seem, the societies were anxious not to refer cases unnecessarily, and hence they wanted to be able to tell which patients were being visited at home. It had therefore been suggested that Form Med. 40 should in future bear the alternative words "at your residence" and "at my surgery," so that by striking out one or other the doctor could indicate where he had seen his patient. Having stipulated that failure to strike out the words should never get the practitioner into trouble, Dr. Dain felt that here perhaps was a convenient occasion for agreement with the societies. But this warm breath of charity had no chance against a blast of six reasons to the contrary with which Dr. J. W. ANDERSON swept the conference. Blood ran cold throughout the room while Dr. Anderson spoke of unscrupulous patients who would strike out the words "at my surgery" so as to avoid going to the R.M.O., and there was a further shudder when he suggested that patients would insist on being seen at home if they got to know that this would save them from having their cases referred.

Two other questions concerning the work of regional medical officers were raised towards the end of the meeting. Dr. J. O. SUMMERHAYES proposed for East Sussex—

> That it be an instruction to the Insurance Acts Committee to take such steps as may be necessary in order to secure that the minimum time within which information required to be given to the regional medical officer shall not be less than seven days instead of 48 hours as at present.

He complained that 48 hours was an inconveniently short time for a reply, but Dr. DAIN said he hoped the conference would not agree to this. The practitioner's object was to get things dealt with expeditiously, and it would be a mistake to pour sand into the Ministry's machinery. The patient ought to go to the R.M.O. as soon as possible after seeing his own doctor, and thanks to a general speeding-up the interval had now been reduced to a week.—The motion was lost.

Dr. G. F. WHYTE, for Dundee, brought forward a motion urging that the present conditions governing appeal or arbitration against the decisions of the R.M.O. or D.M.O. (district medical officer) are unsatisfactory and suggesting that the I.A.C. should negotiate with the Ministry of Health and the Department of Health for Scotland in order to institute a medical board of appeal. Dr. Whyte thought that both patient and panel doctor had grievances. The patient's appeal from the R.M.O.'s decision was heard (if at all) only after long delay during which payment stopped, whilst the doctor had his opinion simply set aside by another doctor—often one, moreover, who saw but little practice and had acquired an official mind. Dundee believed it would be better if doubtful cases were referred to a special medical board.[1] Dr. DAIN agreed that the insured person had a very thin time in appeals against his society, but pointed out that the methods governing such appeals were no concern of the I.A.C. Where a practitioner protested against an R.M.O.'s decision the case was usually referred to another R.M.O. As there was no time for fuller discussion, Dr. Whyte agreed that his resolution should be referred to the I.A.C. for consideration.

Certificates for Convalescence.

On a motion by Hertfordshire suggesting that the medical certification rules might be altered "so that it is not essential that an insured person should have been under the continuous care of one practitioner for 28 days before that practitioner may issue a convalescent certificate," Dr. DAIN said that he thought the I.A.C. should tell the Ministry that the convalescence certificate was dangerous to doctors and useless to anyone else. He had often tried to get the period reduced from a month, and if no alteration could be made he thought that as a measure of safety practitioners should refuse to use this certificate. After properly saying that a person was unfit for work and required convalescent treatment it was undignified to be hauled up because the time happened to be a day short.—This question was referred to the I.A.C., together with a motion by Worcester to the effect that an insured person need only be incapable of work for 14 days, instead of 28, before a certificate may be issued.

At Hertfordshire's suggestion it was also agreed—

> That all National Health Insurance Certificates should have printed on them in red letters, similar to those on the front pages of the medical certificate books, that "These forms are to be used for National Health Insurance purposes only."

Prescribing and Dispensing.

The I.A.C.'s annual report says that the Minister of Health has appointed a central advisory committee to assist insurance committees "to proceed on uniform principles in defining drugs or medicines for the purpose of medical benefit." This committee will be asked to decide whether a substance or preparation is (*a*) never a drug, (*b*) always a drug, or (*c*) sometimes a drug. Since there is at present no way of dealing with insurance practitioners who prescribe on the official form substances which insurance committees do not regard as drugs, the new advisory committee has prepared a draft article which provides machinery for dealing with such cases. Dr. DAIN explained that the proposed regulations were framed on the assumption that this irregular prescribing did not require disciplinary action. and the general principle behind them was that if anything is ordered on a prescription the chemist must dispense it. The draft article was approved by the conference without discussion.

---

[1] Similar views were set out in our correspondence columns on Oct. 19th, p. 850.—ED. L.

The report also says that the I.A.C. has received representations that the cost of such drugs as quinine urethane ampoules should not fall upon the dispensing doctor's 2*s*. 3*d*., or the non-dispensing doctor's 1*s*. 3*d*., per 100 patients, but should be a charge on the drug fund. Dr. DAIN announced that he had now been told by the Ministry that quinine and urethane and similar solutions were shortly to be placed on the list.[2] Dr. H. DICKIE spoke of the increase in the cost of medicines since the early days of the Act, and moved, for Northumberland, "that drugs administered personally by a practitioner, as part of a course of treatment, and not as an emergency, should not be required to be supplied by him at his own expense," as at present prescribed in the terms of service. This resolution, together with one by Northamptonshire about the prescription of liver extract, was referred to the I.A.C. for consideration.

Dr. DAIN reported that the new National Formulary had been adopted in about 50 of the 128 insurance areas in the country. Dr. H. S. BEADLES expressed the view of West Ham that while the new Formulary was part and parcel of the insurance scheme, it had not been prepared for the benefit of practitioners. (Indeed it would prevent them using their own local pharmacopœias.) The distribution should therefore be made gratis. This suggestion commended itself to the conference, which then proceeded to pass the following motion proposed by the I.A.C. :—

> That the Conference supports the Council of the British Medical Association in its efforts to obtain amendment of Section 3 of the 1925 Dangerous Drugs Act, and recommends that heroin and its salts should come under the same conditions as morphine and its salts ; also that the Council should on all possible occasions urge the Government not to enter into international conventions involving medical questions until the opinion of the medical profession has been ascertained.

Encroachment of Hospitals on Private Practice.

Dr. FOTHERGILL, for Brighton, drew attention to the additional benefit which is defined as "payments to hospitals in respect of the maintenance and treatment therein of members, and the payment of the whole or any part of the travelling expenses incurred by or in respect of members in travelling to and from hospitals." The work that should be done by private practitioners, he said, was going to hospitals where it was done gratuitously by medical men. It was essential therefore that certain lines should be laid down for the future, and he proposed a motion "that any scheme prepared by an approved society for the provision of additional benefits to prove acceptable to the medical profession should include the following :

> (*a*) That the arrangements for consultations and specialists' services should provide that these services shall be given, so far as is possible and consistent with the best interests of the patients, by a private practitioner at his consulting rooms or at the patient's own home, and not at the out-patient department of a voluntary or State institution.
>
> (*b*) That approved societies should be able to enter into financial arrangements with both voluntary and State institutions for the provision of hospital benefit for insured persons, such arrangements allowing insured persons to select as between the two classes of institution.
>
> (*c*) That hospital benefit be defined to include in-patient treatment, as also consultant and specialist services, which, consistent with the best interests of the patients, cannot be given by a private practitioner at his consulting rooms or at the patient's own home.

Dr. PETER MACDONALD thought the conference should not commit itself to these definitions without further thought. His experience of ophthalmic benefit showed that it often had to be given at clinics, and his experience of hospital management taught him that it might be quite impossible to make arrangements for insured persons to select the kind of hospital they required. Dr. LOCK also held that the proposals should go to the I.A.C. for consideration, and this suggestion was adopted by the meeting after Dr. SUMMERHAYES had expressed his fear that general practice would be wiped out by the Local Government Act. The time had come, he believed, to make a bold bid to recover the practice now being taken over by hospitals, specialists, and medical officers of health.

The Place of General Practitioners in Hospitals.

This opinion of Dr. Summerhayes' found much support in a subsequent discussion on a motion by Manchester demanding that practitioners should be allowed to attend and treat those of their patients who enter voluntary and municipal hospitals. Dr. E. JOHNSTONE, the proposer, felt that the future of the general practitioner depended on his participation in the work of public hospitals and public health services. Cut off from the instruments of his craft and the coöperation of colleagues he could never rise to be more than a distributor of stomach bottles and cough mixtures.—Dr. M. W. RENTON asked how medical men could become proficient in modern methods if they did not have access to clinics and hospitals.

Dr. BRACKENBURY proposed, as an amendment to the Manchester motion—

> That it is desirable that provision be made in, or in association with, voluntary hospitals and municipal hospitals, or in separate institutions, for practitioners to attend and treat those of their cases who are admitted to such institutions.

Dr. MACDONALD supported this resolution because it went beyond the declared policy of the British Medical Association. It was desirable that general practitioners should have access as soon as possible to the hospitals of the country, which had hitherto been looked on too much as the perquisite of specialists and consultants.

Dr. DAIN spoke of difficulties. The practitioner, he said, often fought shy of appointment to a hospital lest he should be compelled to work there when it was inconvenient. At big hospitals it would often be impossible to give the right of entry to a large number of doctors who could call on the services of the nursing staff. A questionaire had been sent out to voluntary hospitals all over the country, said Dr. Dain, to find out what facilities there already were for general practitioners to keep their patients under observation and treatment.

Sir RICHARD LUCE said that while he was in favour of general practitioners having access to hospitals for their patients, it was difficult to alter the closed system of staffing where it was already established. The hospitals to be transferred to municipalities offered a great chance to develop the work of practitioners in new places instead of disturbing the good work now being done.

Sir ROBERT BOLAM asked what the general practitioner really wanted in the hospital. Did he want to do general work or consultant work ? In voluntary hospitals did he want to compete with the honorary staff, or did he want to do the work of house surgeon or house physician ? Sir Robert thought the question should be referred to the I.A.C. for report.

Dr. D. C. MCARDLE had come to the conclusion that what most practitioners wanted was to be allowed to start their careers all over again, which was impossible. The real opportunity lay with the young men now coming out of the universities, who must not be allowed to fall into the rut of their predecessors in general practice.

Dr. SUMMERHAYES said that what he himself wanted was to be able to go into the hospital and see that his patient's broken leg had been set properly and was being nursed properly. He wanted to be able to do lots of things, including minor operations, which general practitioners could do perfectly well if they had the chance—indeed, much better than they were being done now.

---

[2] In a recent "range of service" case the referees decided that the treatment of varicose veins in the leg by intravenous injections is within the range of an insurance practitioner's agreement.

Dr. Brackenbury's amendment was carried, and a proposal to refer the subject to the I.A.C. was lost (by a small majority) because the conference wished to express its general opinion at once.

Periodic Examination of Insured Persons.

Early this year the Lancashire Insurance Committee tried to get a ruling that healthy people are entitled to periodic medical examination by their panel doctors. The local panel committee objected, and maintained that a fee should be charged for a service of this kind. The I.A.C., though it did not dispute that it is part of the doctor's duty to examine any insured person who presents himself in the ordinary course of practice, informed the Ministry that it is of opinion that periodic and systematic examination of insured persons who believe themselves to be in good health is not within the present contract of insurance practitioners. Lancashire brought before the conference a resolution arising out of this decision, and calling for modification of the definition of the range of service. But Dr. DAIN persuaded the meeting to leave the problem alone for the present. The demand for examinations of this kind did not yet constitute any burden, and the fact that no fee need be demanded enabled medical men to deal in a human way with patients who asked a perfectly natural question. The trend of public opinion was such that in course of time panel practitioners would probably be asked on what terms they would render this service to all insured persons.

Importance of Keeping Medical Records.

Dr. C. EDE, for Wiltshire, proposed :—

That the conference instructs the Insurance Acts Committee to take steps to impress on every insurance practitioner the fact that owing to neglect in keeping the statutory medical records, many men are furnishing regional medical officers, and thus the Ministry, with misleading evidence which suggests that they are being overpaid, and are therefore jeopardising not only their own income, but those of their fellow practitioners.

It was an open secret, he said, that all over the country men were failing to put down all their attendances on the record cards. This would not matter a bit if it were not that R.M.O.'s were collecting the cards and analysing the figures at the Ministry. As it was, a day of reckoning was at hand. When the question of revision of the capitation fee was raised again these figures would be a trump card in the hands of the Ministry. The practitioners' representatives would either have to accept them or admit their inaccuracy—in which case the Ministry would retort : "But you've been *paid* to keep these records." There were only two ways out of the difficulty. If the profession was sufficiently strong and united it could refuse to have anything to do with records of attendances and visits—excluding clinical records, which were useful to the doctor and his patient. The other alternative was to take the action suggested by the Wiltshire motion.—Dr. DAIN described the present situation as "very awkward," and the motion was passed.

A Hardship for Pregnant Women.

Dr. J. J. BEKENN, for Birmingham, spoke of the resentment caused by approved societies sending pregnant women to the R.M.O. when they were nearing term. He proposed—

That when a medical practitioner has satisfied himself that an insured person is so far advanced in pregnancy that on that account she will not be able to work again until after her confinement, it shall be lawful for him to give a certificate to that effect, stating that the woman is unable to follow her employment, and that such certificate shall be sufficient warranty to pay the sick benefit until the termination of the pregnancy.

Dr. O. B. TRUMPER anticipated criticism of this motion by pointing out that quite a large number of the women were not going to be attended by the practitioner at confinement and therefore need not visit him.—Dr. A. W. HOLTHUSEN told of a chambermaid, pregnant eight months, who was described by her practitioner as unfit to work. Her approved society referred the case to the R.M.O., who saw her at eight and a half months and said she was fit to go on with her work as a chambermaid. The approved society then brought a charge of lax certification against the panel doctor!—The resolution was referred to the I.A.C., after the opinion had been expressed that it was very valuable to have patients calling weekly at the surgery during the last six weeks of their pregnancy.

The Range of Service.

Dr. FOTHERGILL, for Brighton, introduced a motion laying it down that when it has been decided that an operation or other service is outside the scope of a practitioner's obligation, it is no concern of any committee or authority to decide that the practitioner who renders the service has appropriate skill or experience.—This motion produced a long discussion, in the course of which Dr. DAIN said it was quite time that this question was reconsidered, inasmuch as new methods of treatment were continually being evolved which were outside the terms of contract but could easily be learnt. His suggestion that the resolution should have the attention of the I.A.C. was accepted.

Dr. RENTON proposed that the I.A.C. be instructed to draw up a list of services outside the contract of the insurance doctor. He thought that these should include the injection treatment of varicose veins, which was by no means easy, and should not be approached lightly. He had asked some junior surgeons at an injection clinic whether they would rather stake their reputations on 100 unselected cases of varicose veins or on 100 unselected cases of appendicitis. The answer was "the appendix every time."—Dr. DAIN asked the conference not to pass the motion. It was not the business of the I.A.C. to draw up a list, and anyone could obtain the Ministry's list on application.—His appeal was successful.

Miscellaneous Topics.

The three following motions were passed on the proposal of Newcastle-upon-Tyne, Kingston-upon-Hull, and Cumberland respectively :—

That in the opinion of the medical profession additional treatment benefits should be uniform and available to every insured person.

That the conference is of opinion that medical record cards should not be produced at a hearing before a medical service subcommittee without the consent of the insured person having first been obtained, except when such production is considered necessary, in his own defence, by the practitioner concerned ; and that the clerk to an insurance committee has no right to demand the production of a medical card for medical service subcommittee purposes.

That the Insurance Acts Committee be requested to consider the position of insured persons resident in convalescent homes in regard to being signed on by the medical officers in charge as temporary residents, whether they require medical treatment or not.

A motion was put forward by Buckinghamshire asking the I.A.C. to press for "further recognition by the Ministry of Health of the value of timeage and mileage spent by rural doctors on their insured patients." This motion was lost.

Dr. H. J. Cardale was elected chairman of the conference for the coming year, and the thanks of the conference were given to Dr. Le Fleming for his conduct in the chair.

PRESENTATION TO A PLYMOUTH SURGEON.—On Oct. 11th Mr. T. Young Simpson was presented with a walnut compactum cupboard and an illuminated autograph book from many of his medical colleagues on his retirement from practice owing to ill-health due to overwork. Mr. Simpson has had a large surgical practice in Plymouth and the surrounding districts since 1906, and his enforced retirement will be keenly felt by many of his medical confrères and a great number of the general public.

MEDICINE AND THE LAW.

Coroner's Inquest and Police Proceedings.

AT the resumption recently of an adjourned inquest due to a traffic accident the coroner for South-East London complained that the police had interrupted the course of his inquiry. Two Lewisham men were fatally injured on August 31st, being run into by a private motor-car. On the night before the inquest the police arrested the driver of the motor-car and thereby, as the coroner contended, interfered both with the immemorial privilege of the coroner's jury to inquire into the death of two local inhabitants and also with the driver's right to give his own account of the incident at the earliest possible moment to the coroner and his jury. The magistrates committed the driver for trial, and he was sentenced to six months imprisonment on Oct. 17th at the Old Bailey.

The concurrent operation of a coroner's inquest and of criminal proceedings before a magistrate in cases of homicide was a duplication of machinery which engaged the attention of the Departmental Committee on Coroners 20 years ago. It had two prominent features: it wasted the time of witnesses (not to mention the accused) in attendance at successive stages of two parallel investigations, and secondly, it caused an overlapping of committals by the coroner and the magistrates. In this latter connexion it was on record that a person accused of manslaughter on board ship was once committed by a coroner for trial at Exeter Assizes and by the magistrates for trial at Bodmin. In addition to this cause of unnecessary inconvenience and expense there were the two difficulties that committal by a coroner often follows the reception of evidence not strictly admissible in the assize court, and that in practice the prosecution always preferred to act on the magisterial proceedings rather than on the inquest. On the other hand, there were instances where the dismissal of a charge before the magistrates was followed by successful prosecution at assizes on the coroner's committal. When at length Parliament dealt with these matters in the Coroners (Amendment) Act of 1926, it decided to end the duplication by suspending the inquest. Under Section 20 if, before a coroner's jury has given its verdict, the coroner is informed that someone has been charged before examining justices with the murder, manslaughter, or infanticide of the deceased, the coroner "shall, in the absence of reason to the contrary, adjourn the inquest" till the criminal proceedings are over. When the latter proceedings are concluded, the coroner "may . . . resume the adjourned inquest if he is of opinion that there is sufficient cause to do so." One adequate "reason to the contrary" against an adjournment would be, as the editor of Jervis on Coroners observes, the desirability of receiving the report of an analysis already ordered. One "sufficient cause" for resuming an inquest would be to avert a failure of justice where magistrates have refused to commit for trial. The editor of Jervis adds his opinion that in all street accidents the coroner should certainly complete his inquiry.

The brief report of the inquest at Lewisham mentions the arrest of a person by the police, not the charging of that person before the magistrates. It is the latter, not the former, step which is the condition precedent to adjournment of the inquest. A coroner might be able to conclude his inquiry notwithstanding arrest; in any case he can (and, in the Lewisham case, no doubt rightly did) complete it later. The police, of course, are under no obligation to time their moves in a case of suspected homicide so as to suit the coroner. As, however, the relations of coroner and police are mutually helpful, it is undesirable that one inquiry should seem to be jockeying the other for position. Some part of Major Whitehouse's complaint is in effect directed not against the action of the police to-day but against that of Parliament in 1926. In some respects, as the British Medical Association stated to the Departmental Committee many years ago, the office of coroner is a vestigial structure. Parliament is unlikely to restore to that office the power which it took away in 1926; it may even make yet further inroads, though the Home Secretary has just announced his view that the amending legislation of 1926 is sufficient for the present.

SURGICAL CATGUT.

THE preparation of surgical catgut involves the production of material which is free from bacterial contamination, and yet remains flexible, strong, and absorbable. Lord Lister, who introduced sterilised catgut into surgical use, spent 40 years in attempting to improve its manufacture, and the Medical Research Council, in a preface to a green book[1] published to-day, state that the work recorded therein stands in historical succession to his classical studies. They draw attention to the dilemma by which the catgut maker is confronted. Catgut can be efficiently sterilised, but every method of disinfection has some effect in diminishing the tensile strength of the ligature, upon which its surgical value and the safety of the patient depends. The efforts of Prof. Bulloch and his colleagues have been directed to ascertaining the methods by which bacteriological sterility can be achieved with least damage to the physical qualities of the material. Their investigations have had among valuable positive results at least one negative finding of importance—the discredit of biniodide of mercury as a suitable sterilising agent. The general conclusions reached are summarised as follows:—

1. It has been shown that the pH of the collagen ribbon wash liquid is an important factor in the production of ligatures. To prevent degradation a wash liquid of pH 4·7 is required, but for optimum strength pH 8–9. A compromise may be effected by carrying through most of the process of washing in a solution of pH 4·7 and finishing with a bath of alkali at pH 8–9. For this same reason the ribbons should not be washed in water before spinning.

2. Optimum strength of ligature is obtained by using narrow ribbons and spinning each individually and then collectively, so that each ribbon makes 2·5 turns per inch and then collectively a further 5 turns per inch. It is important that the spinning should be uniform otherwise the strength and diameter along its length will vary.

3. It has been shown that when ligature is treated with iodine an acid is produced which is harmful for the reason given in (1). Means of reducing or eliminating this effect have been worked out by the use of potassium iodate.

4. It has been demonstrated that the treatment of ligature for 8–9 days in such a way that it absorbs 12 per cent. of its weight of iodine ensures sterility.

5. The disadvantages of excessive treatment with iodine have been demonstrated and the advantages of removing the iodine from the ligature after sterilising indicated.

6. Data have been obtained whereby control of the amount of the absorbed iodine may be obtained.

7. The advantages of incorporating glycerol in the iodine solution and in the final alcohol solution have been illustrated, particularly from the point of view of flexibility of the ligature, and therefore, strength of the knot.

8. It has been shown that the ligature in aqueous iodine swells. This may be reduced by treating it under tension, when its tensile strength is increased.

Important practical issues are raised by this report. Deaths from tetanus and other infections are known to have resulted from the use of contaminated ligatures, and though fatal results attributed to the use of imperfect catgut are numerically very rare indeed in relation to the vast total number of ligatures used in surgical operations, it is nevertheless recorded that some infection was found in every one of eight batches of catgut ligatures purchased in 1927. The data given in this report and the experience gained in obtaining them have already been useful in the guidance of administrative action. The licensing authority under the Therapeutic Substances Act has decided to add surgical catgut to the list of substances subject to control under the Act, and in the future the profession and the public will have better guarantees that catgut supplied has, in fact, the purity and quality claimed for it.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

National Health Insurance.

THE second reading debate in the Dail last week on the National Health Insurance Bill, 1929, gave the opportunity for a discussion of many of the problems of national health insurance. The Bill, the second reading of which was moved by Mr. R. Mulcahy, Minister for Local Government and Public Health, is intended to give effect to some of the minor recommendations of the committees of inquiry which reported in 1925 and 1927. It proposes to abolish the class of deposit contributor, and to make consequential changes in regard to the power of societies to refuse or expel members. It also proposes to abolish insurance committees, and to transfer their powers and functions to the county boards of health. The funds formerly available for the insurance committees will be diverted toward the expenses of medical certification. The Minister said he had hoped to deal with the question of amalgamation of societies by an amendment to the present Bill, but he found that it would be more convenient to deal with it in a second measure. He intended, therefore, after Christmas to introduce a Bill containing proposals concerning amalgamation. It would encourage voluntary amalgamation, and would give power to the National Health Insurance Commissioners, after a period of two years, to effect compulsory amalgamation to a maximum number of 12 or 15 societies for the whole State. At present there were 65 societies. Compensation, but not pensions, would be granted to employees whose services might be dispensed with as a result of amalgamation. The Minister stated that he was not at present putting forward any proposals for medical benefit, but that personally he thought some system of medical benefit was desirable. The effecting of economies in administration would hasten the day when they would have medical benefit. Mr. O'Kelly, of the Fianna Fail party, moved an amendment declining to give a second reading to the Bill, until proposals should be laid before the Dail providing for (1) administration through one society, and (2) medical benefits. He explained, however, that, while his party thought certain amendments necessary, they did not intend to oppose the Bill. He believed that the establishment of a system of medical benefits would improve the public health, and put a stop to the wastage of life all over the Saorstát. Mr. O'Connell, leader of the Labour Party, was also in favour of medical benefits: he thought nationalisation of the administration of national health insurance was to be preferred to any modification of the present system of administration by approved societies. In this he was supported by Dr. T. Hennessy. The latter also spoke of the necessity of a system of medical benefit, and favoured the establishment of a national medical service which would provide medical attendance not only for the insured but for their dependents. He quoted figures to show that at present in the cities the poor-law medical service was inadequate to give medical attendance to the workers and their families. Several other deputies spoke in favour of a medical benefit, and none spoke against it. This unanimity in all parts of the House is gratifying, and should render the Minister's task easier when he finds himself in a position to tackle it. His chief opposition comes, one may assume, from the Department of Finance. The proposed establishment of a system of medical benefits in Northern Ireland will render the problem more pressing in the Irish Free State, which up to the present has shown a more progressive spirit in matters of health than the Northern Province. The present Bill was given a second reading.

HYDROLOGY AND RHEUMATISM.

THE BUDAPEST CONFERENCE.

THE International Society of Medical Hydrology, in association with the International League against Rheumatism, has held its annual meeting this year from Oct. 13th–18th in Budapest, under the presidency of Baron KORÁNYI, professor of internal medicine; with three subsequent days in Austria. About 800 members and guests attended the meetings, representing 21 countries; Russia, Finland, Bulgaria, and Norway being represented for the first time. Receptions were accorded to the Society by the Regent, the Ministry of Social Welfare and Labour, the Ministry of Agriculture, the Lord Mayor of Budapest, and the Hungarian Balneological Society, and opportunity was found for examining the many establishments for thermal and mud baths in the city, including the popular Wave and Strand Baths.

A new Committee on Social Hydrology was appointed by the Society, and the existing facilities for treatment of insured persons were studied both in Hungary and Austria. Groups of rheumatic cases were investigated at the Szt. Lukács Baths at Budapest and the Wenckebach Clinic in Vienna.

The Action of Hypertonic Waters.

Hungary is rich in hypertonic bitter waters like those of Hunyadi János. Prof. DALMADY (Budapest) referred to the fact that the SO_4 ion which they contained increased secretion and transudation by the intestinal mucous membrane, but not the concentration of the blood. He showed that stronger Glauber's salt solutions were irritant and increased the formation of mucus, whilst the bitter waters had been drunk for many years without irritation and without any increase of alkali loss. They were of value in causing effortless evacuation, and in larger doses in medical and surgical practice where free purgation was desired; also for prolonged use in arterio-sclerosis and congestive cases with a tendency to hæmorrhage, and especially in certain toxæmias. Many chronic diseases were amenable to hypertonic waters, according to the old doctrine "qui bene purgat bene curat." An unbiased re-examination of this method of treatment was called for.

Prof. PINILLA (Madrid) contributed observations on the cryoscopy and viscosity of the hypertonic waters of Spain, of which that at Carabaña was a type. It had been clearly shown that a nervous stimulus was necessary for endosmosis, and Sanarelli had suggested that purgation was due to the stimulation of the nervous network by dissociated ions. Probably the process of purgation was brought about by the formation of hydrophile colloids and their supersaturation, analogous processes to those which took place in vegetable tissues in springtime, leading to the abundant production of liquids.

Dr. HARPUDER, Director of the Balneological Research Institute at Wiesbaden, pointed out that the SO_4 ions were difficult of resorption. In concentrated solutions they powerfully stimulated secretion by the bowel, hindered the resorption of other substances, and set up peristaltic waves. They also relaxed the sphincter of the gall-bladder. He found that hypertonic waters did cause a degree of inspissation of the blood as well as some increase of total metabolism.

Dr. FORTESCUE FOX (London) held that hypertonic waters (in England Harrogate, Cheltenham, Leamington) had their chief indication in the prophylactic treatment of the congestive conditions commonly met with in middle life, leading to variously located crises in the digestive, circulatory, and nervous systems.

The Action of Baths in Cardiovascular Disease.

Dr. Fr. SCHMIDT (Hungary), from his experience on Lake Balaton, believed that the most important effects of CO_2 baths were the changes that take

MEDICINE AND THE LAW.

Coroner's Inquest and Police Proceedings.

AT the resumption recently of an adjourned inquest due to a traffic accident the coroner for South-East London complained that the police had interrupted the course of his inquiry. Two Lewisham men were fatally injured on August 31st, being run into by a private motor-car. On the night before the inquest the police arrested the driver of the motor-car and thereby, as the coroner contended, interfered both with the immemorial privilege of the coroner's jury to inquire into the death of two local inhabitants and also with the driver's right to give his own account of the incident at the earliest possible moment to the coroner and his jury. The magistrates committed the driver for trial, and he was sentenced to six months imprisonment on Oct. 17th at the Old Bailey.

The concurrent operation of a coroner's inquest and of criminal proceedings before a magistrate in cases of homicide was a duplication of machinery which engaged the attention of the Departmental Committee on Coroners 20 years ago. It had two prominent features: it wasted the time of witnesses (not to mention the accused) in attendance at successive stages of two parallel investigations, and secondly, it caused an overlapping of committals by the coroner and the magistrates. In this latter connexion it was on record that a person accused of manslaughter on board ship was once committed by a coroner for trial at Exeter Assizes and by the magistrates for trial at Bodmin. In addition to this cause of unnecessary inconvenience and expense there were the two difficulties that committal by a coroner often follows the reception of evidence not strictly admissible in the assize court, and that in practice the prosecution always preferred to act on the magisterial proceedings rather than on the inquest. On the other hand, there were instances where the dismissal of a charge before the magistrates was followed by successful prosecution at assizes on the coroner's committal. When at length Parliament dealt with these matters in the Coroners (Amendment) Act of 1926, it decided to end the duplication by suspending the inquest. Under Section 20 if, before a coroner's jury has given its verdict, the coroner is informed that someone has been charged before examining justices with the murder, manslaughter, or infanticide of the deceased, the coroner "shall, in the absence of reason to the contrary, adjourn the inquest" till the criminal proceedings are over. When the latter proceedings are concluded, the coroner "may . . . resume the adjourned inquest if he is of opinion that there is sufficient cause to do so." One adequate "reason to the contrary" against an adjournment would be, as the editor of Jervis on Coroners observes, the desirability of receiving the report of an analysis already ordered. One "sufficient cause" for resuming an inquest would be to avert a failure of justice where magistrates have refused to commit for trial. The editor of Jervis adds his opinion that in all street accidents the coroner should certainly complete his inquiry.

The brief report of the inquest at Lewisham mentions the arrest of a person by the police, not the charging of that person before the magistrates. It is the latter, not the former, step which is the condition precedent to adjournment of the inquest. A coroner might be able to conclude his inquiry notwithstanding arrest; in any case he can (and, in the Lewisham case, no doubt rightly did) complete it later. The police, of course, are under no obligation to time their moves in a case of suspected homicide so as to suit the coroner. As, however, the relations of coroner and police are mutually helpful, it is undesirable that one inquiry should seem to be jockeying the other for position. Some part perhaps of Major Whitehouse's complaint is in effect directed not against the action of the police to-day but against that of Parliament in 1926. In some respects, as the British Medical Association stated to the Departmental Committee many years ago, the office of coroner is a vestigial structure. Parliament is unlikely to restore to that office the power which it took away in 1926; it may even make yet further inroads, though the Home Secretary has just announced his view that the amending legislation of 1926 is sufficient for the present.

SURGICAL CATGUT.

THE preparation of surgical catgut involves the production of material which is free from bacterial contamination, and yet remains flexible, strong, and absorbable. Lord Lister, who introduced sterilised catgut into surgical use, spent 40 years in attempting to improve its manufacture, and the Medical Research Council, in a preface to a green book[1] published to-day, state that the work recorded therein stands in historical succession to his classical studies. They draw attention to the dilemma by which the catgut maker is confronted. Catgut can be efficiently sterilised, but every method of disinfection has some effect in diminishing the tensile strength of the ligature, upon which its surgical value and the safety of the patient depends. The efforts of Prof. Bulloch and his colleagues have been directed to ascertaining the methods by which bacteriological sterility can be achieved with least damage to the physical qualities of the material. Their investigations have had among valuable positive results at least one negative finding of importance—the discredit of biniodide of mercury as a suitable sterilising agent. The general conclusions reached are summarised as follows:—

1. It has been shown that the pH of the collagen ribbon wash liquid is an important factor in the production of ligatures. To prevent degradation a wash liquid of pH 4·7 is required, but for optimum strength pH 8–9. A compromise may be effected by carrying through most of the process of washing in a solution of pH 4·7 and finishing with a bath of alkali at pH 8–9. For this same reason the ribbons should not be washed in water before spinning.
2. Optimum strength of ligature is obtained by using narrow ribbons and spinning each individually and then collectively, so that each ribbon makes 2·5 turns per inch and then collectively a further 5 turns per inch. It is important that the spinning should be uniform otherwise the strength and diameter along its length will vary.
3. It has been shown that when ligature is treated with iodine an acid is produced which is harmful for the reason given in (1). Means of reducing or eliminating this effect have been worked out by the use of potassium iodate.
4. It has been demonstrated that the treatment of ligature for 8–9 days in such a way that it absorbs 12 per cent. of its weight of iodine ensures sterility.
5. The disadvantages of excessive treatment with iodine have been demonstrated and the advantages of removing the iodine from the ligature after sterilising indicated.
6. Data have been obtained whereby control of the amount of the absorbed iodine may be obtained.
7. The advantages of incorporating glycerol in the iodine solution and in the final alcohol solution have been illustrated, particularly from the point of view of flexibility of the ligature, and therefore, strength of the knot.
8. It has been shown that the ligature in aqueous iodine swells. This may be reduced by treating it under tension, when its tensile strength is increased.

Important practical issues are raised by this report. Deaths from tetanus and other infections are known to have resulted from the use of contaminated ligatures, and though fatal results attributed to the use of imperfect catgut are numerically very rare indeed in relation to the vast total number of ligatures used in surgical operations, it is nevertheless recorded that some infection was found in every one of eight batches of catgut ligatures purchased in 1927. The data given in this report and the experience gained in obtaining them have already been useful in the guidance of administrative action. The licensing authority under the Therapeutic Substances Act has decided to add surgical catgut to the list of substances subject to control under the Act, and in the future the profession and the public will have better guarantees that catgut supplied has, in fact, the purity and quality claimed for it.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

National Health Insurance.

THE second reading debate in the Dail last week on the National Health Insurance Bill, 1929, gave the opportunity for a discussion of many of the problems of national health insurance. The Bill, the second reading of which was moved by Mr. R. Mulcahy, Minister for Local Government and Public Health, is intended to give effect to some of the minor recommendations of the committees of inquiry which reported in 1925 and 1927. It proposes to abolish the class of deposit contributor, and to make consequential changes in regard to the power of societies to refuse or expel members. It also proposes to abolish insurance committees, and to transfer their powers and functions to the county boards of health. The funds formerly available for the insurance committees will be diverted toward the expenses of medical certification. The Minister said he had hoped to deal with the question of amalgamation of societies by an amendment to the present Bill, but he found that it would be more convenient to deal with it in a second measure. He intended, therefore, after Christmas to introduce a Bill containing proposals concerning amalgamation. It would encourage voluntary amalgamation, and would give power to the National Health Insurance Commissioners, after a period of two years, to effect compulsory amalgamation to a maximum number of 12 or 15 societies for the whole State. At present there were 65 societies. Compensation, but not pensions, would be granted to employees whose services might be dispensed with as a result of amalgamation. The Minister stated that he was not at present putting forward any proposals for medical benefit, but that personally he thought some system of medical benefit was desirable. The effecting of economies in administration would hasten the day when they would have medical benefit. Mr. O'Kelly, of the Fianna Fail party, moved an amendment declining to give a second reading to the Bill, until proposals should be laid before the Dail providing for (1) administration through one society, and (2) medical benefits. He explained, however, that, while his party thought certain amendments necessary, they did not intend to oppose the Bill. He believed that the establishment of a system of medical benefits would improve the public health, and put a stop to the wastage of life all over the Saorstát. Mr. O'Connell, leader of the Labour Party, was also in favour of medical benefits: he thought nationalisation of the administration of national health insurance was to be preferred to any modification of the present system of administration by approved societies. In this he was supported by Dr. T. Hennessy. The latter also spoke of the necessity of a system of medical benefit, and favoured the establishment of a national medical service which would provide medical attendance not only for the insured but for their dependents. He quoted figures to show that at present in the cities the poor-law medical service was inadequate to give medical attendance to the workers and their families. Several other deputies spoke in favour of a medical benefit, and none spoke against it. This unanimity in all parts of the House is gratifying, and should render the Minister's task easier when he finds himself in a position to tackle it. His chief opposition comes, one may assume, from the Department of Finance. The proposed establishment of a system of medical benefits in Northern Ireland will render the problem more pressing in the Irish Free State, which up to the present has shown a more progressive spirit in matters of health than the Northern Province. The present Bill was given a second reading.

HYDROLOGY AND RHEUMATISM.

THE BUDAPEST CONFERENCE.

THE International Society of Medical Hydrology, in association with the International League against Rheumatism, has held its annual meeting this year from Oct. 13th–18th in Budapest, under the presidency of Baron KORÁNYI, professor of internal medicine; with three subsequent days in Austria. About 300 members and guests attended the meetings, representing 21 countries; Russia, Finland, Bulgaria, and Norway being represented for the first time. Receptions were accorded to the Society by the Regent, the Ministry of Social Welfare and Labour, the Ministry of Agriculture, the Lord Mayor of Budapest, and the Hungarian Balneological Society, and opportunity was found for examining the many establishments for thermal and mud baths in the city, including the popular Wave and Strand Baths.

A new Committee on Social Hydrology was appointed by the Society, and the existing facilities for treatment of insured persons were studied both in Hungary and Austria. Groups of rheumatic cases were investigated at the Szt. Lukács Baths at Budapest and the Wenckebach Clinic in Vienna.

The Action of Hypertonic Waters.

Hungary is rich in hypertonic bitter waters like those of Hunyadi János. Prof. DALMADY (Budapest) referred to the fact that the SO_4 ion which they contained increased secretion and transudation by the intestinal mucous membrane, but not the concentration of the blood. He showed that stronger Glauber's salt solutions were irritant and increased the formation of mucus, whilst the bitter waters had been drunk for many years without irritation and without any increase of alkali loss. They were of value in causing effortless evacuation, and in larger doses in medical and surgical practice where free purgation was desired; also for prolonged use in arterio-sclerosis and congestive cases with a tendency to hæmorrhage, and especially in certain toxæmias. Many chronic diseases were amenable to hypertonic waters, according to the old doctrine "qui bene purgat bene curat." An unbiased re-examination of this method of treatment was called for.

Prof. PINILLA (Madrid) contributed observations on the cryoscopy and viscosity of the hypertonic waters of Spain, of which that at Carabaña was a type. It had been clearly shown that a nervous stimulus was necessary for endosmosis, and Sanarelli had suggested that purgation was due to the stimulation of the nervous network by dissociated ions. Probably the process of purgation was brought about by the formation of hydrophile colloids and their supersaturation, analogous processes to those which took place in vegetable tissues in springtime, leading to the abundant production of liquids.

Dr. HARPUDER, Director of the Balneological Research Institute at Wiesbaden, pointed out that the SO_4 ions were difficult of resorption. In concentrated solutions they powerfully stimulated secretion by the bowel, hindered the resorption of other substances, and set up peristaltic waves. They also relaxed the sphincter of the gall-bladder. He found that hypertonic waters did cause a degree of inspissation of the blood as well as some increase of total metabolism.

Dr. FORTESCUE FOX (London) held that hypertonic waters (in England Harrogate, Cheltenham, L[illegible]mington) had their chief indication in the prophylactic treatment of the congestive conditions, commonly met with in middle life, leading to vario[illegible] located crises in the digestive, circulatory, [illegible] nervous systems.

The Action of Baths in Cardiovascul[illegible] Dis[illegible]

Dr. Fr. SCHMIDT (Hungary), from [illegible] exper[illegible]th cam- Lake Balaton, believed that the most [illegible] the treat- effects of CO_2 baths were the changes [illegible] SACCHARIN place in vascular tone, and in the rhythm and volume of the pulse. By varying the stimuli in the bath—thermal, chemical, and mechanical—the effect of the bath could be altered at will, so as to increase or diminish the work of the heart. It was probable that with the dilatation of the superficial vessels the coronary arteries were also dilated. The above stimuli could be so combined in the CO_2 bath as to have a purely sedative effect on the nerve centres and were hence often of value in hypertension and even angina pectoris.

Dr. A. **MOUGEOT** (France) found natural CO_2 baths of special value at the onset of cardiac failure. If properly given they were vasodilator and cardiotonic and could be safely used even in cases of extreme hypertension. He agreed with the German school of hydrology that patients with cardiovascular disease have everything to gain from baths and little or nothing from the ingestion of cold waters.

Dr. **KORNMANN** (Switzerland) agreed that every balneotherapeutic irritation-complex could be regulated according to its form and time doses, and that in many cases of circulatory disturbance an individual optimum of the circulatory dynamic could be brought about and maintained as a result of bath treatment.

Two discussions took place at the meetings of the Ligue International contre le Rheumatisme:

*The Relation Between Acute and Chronic Rheumatism.**

Docent Dr. **JULIUS VON BENCZUR** (Budapest) pointed out that the word rheumatism was used to include: (1) diseases of the organs of locomotion, excluding only the nervous and traumatic; or (2) every inflammatory affection about the joints of unknown cause; or (3) diseases produced by chill, irrespective of the common bacterial and metabolic factors. He regarded chronic rheumatism as a chain of constantly recurring reactions to rapidly repeated stimuli. Arthritis and peri-arthritis might arise purely from chill. There was a constant struggle between causes and resistance; the weaker the resistance, the stronger was the disease, and the greater was the effect of small causes. He agreed with the French conception, which the Germans also admitted, that certain subjects were "candidates for arthritic disease," by permanent or temporary predisposition from some metabolic irregularity. In such subjects chill might induce acute rheumatism, especially when accompanied by fatigue, which was also an important factor of causation. In the German Army 60 per cent. of cases of acute rheumatism occurred during the first year of service. A common disturbance in all forms of rheumatism was dysfunction of the small arteries and capillaries of the skin, with failure of the normal reaction to cold and heat and disturbance of blood-supply due to atony or hypertonia of these vessels. With reference to age-incidence in Hungary, the period of acute rheumatism was from puberty to 40 years, two-thirds of the deaths occurring between the ages of 5 and 25; muscular rheumatism and neuralgias, from puberty to 60; sciaticas and lumbagos, from 30 to 60; acute and subacute muscular rheumatism, from puberty to the climacteric, and primary chronic arthritis in the 'fifties.

Docent Dr. **ERNST FREUND** (Vienna) held that acute rheumatism was perhaps decreasing but more often than formerly passed over into a chronic stage in later years, from hereditary or acquired constitution. This was partly a senile change. The chronic cases without heart affection differed from the acute both clinically and prognostically.

Docent Dr. **GUNNAR KAHLMETER** (Sweden) said that in Sweden the arthritis which ran a chronic course from the outset was far more common than that which followed an acute attack; but it presented clinical features indicative of infection. These were: [illegible] elevations of temperature, blood changes [illegible] slight leucocytosis with [illegible] compr[illegible]mia, [illegible] of the [illegible] in 1926. displacement to the left in earlier cases and relative lympho- and mono-cytosis in more advanced cases, also increased V.S.); chronic endocarditis in 25–40 per cent. cases; emaciation and muscular weakness, and clammy skin. Besides this common (probably infective) form of arthritis, "climacteric arthritis" (probably not infective) was common in Sweden; monoarthritis and osteoarthritis were also to be classed as non-infective. He favoured Weil's view that rheumatic fever is not merely an acute disease but rather an illness like syphilis or tubercle, liable to recurrence in a chronic form after apparent recovery; and he believed that both the acute and chronic diseases might probably be due to a pure infection of the same virus, differing in virulence and the reaction provoked.

*The Hæmatology of Rheumatic Disease.**

Dr. **BILKEI PAP** (Budapest) agreed that many cases must be attributed to constitutional inferiority or diathesis, probably due to a disturbance of the vegeto-nervous system and which was unable to react towards infection. There was no characteristic blood picture and he therefore held that rheumatic polyarthritis was not a septicæmia. Much importance attached to the chemical and physical analysis of the blood albumins. Increases in fibrinogen and globulin and of flocculation could be measured and used for differential diagnosis. The precipitation (V.S.) test was also of much value. Infective forms of disease showed increased precipitation, but this test gave definitely normal results in degenerative, traumatic, and metabolic rheumatism.

Dr. **ARNOLD ZIMMER** (Berlin) stressed the frequency of association of arthritis with endocrine disturbance. There were many purely endocrine cases in which no infection was found and many infective cases in which no endocrine trouble was found, but there were many mixed forms differentiated by endocrine reactions, the majority being ovarian. Abderhalden had devised a method for determining the endocrine factor by an examination of the serum. The presence of endocrine albumins like that of other foreign albumins liberated a defensive ferment which destroyed these foreign bodies. The presence of the products of destruction could be measured by an interferometer and it was claimed that very minute alterations in the concentration of the serum could be detected. In healthy serums the proportion of derivatives from the several endocrine albumins was not constant but the relation between the products of the various endocrines was constant. He held that rheumatic cases showed departures from this normal relation.

Dr. **ANTON FISCHER** (Landesbad Rheumatism Research Institute at Aachen) discussed alteration in the albuminous bodies of the serum from the standpoint that rheumatism was a general disease with undiscovered abnormalities of metabolism. The sedimentation test had clearly differentiated cases showing active and inflammatory processes of every kind, but he had found that non-febrile chronic polyarthritis gave very high sedimentation rates, although many had no inflammatory symptoms. The explanation of increased sedimentation had still to be determined. It now appeared, however, that this increase was accompanied by a chemical alteration in the white corpuscles, 80 per cent. of cases showing increase of globulin. There was consequently increase of tryptophan and corresponding diminution of cystin. Severe arthritis also showed increased viscosity of the serum. The increase in a chemically different globulin seemed a definite finding. The lowered sugar tolerance observed by Pemberton in acute inflammatory arthritis was associated in the Aachen findings with increased sedimentation rate, but no liver abnormality was discovered. With regard to other blood conditions in rheumatism, Dr. Fischer found no definite changes in acid-base equilibrium, [illegible]lthough there was some diminution of the blood [illegible]aline reserve in inflammatory cases. With [illegible]erton and Race he found normal values for blood calcium, but observed no increase in excretion of sulphur with Cawadias, nor diminution of basic *metabolism with Pemberton. He doubted the value* of the Abderhalden method but spoke favourably of the possibilities of an immuno-diagnostic method.

---

* [illegible]ta Rheumatologica, Anno I., [illegible] W. L. and J. Brusse's Uitgev[illegible]

Mr. JOSEPH RACE (Devonshire Hospital, Buxton) communicated some recent work showing that out of 100 cases of "rheum-arthritis" 68 had a count exceeding 9000 white blood cells, mainly leucocytes, but a number of cases had a low count. The latter were generally cases of long duration, showing a poor response to treatment. There was no leucocytosis in climacteric arthritis, and there appeared to be no correlation between increase of white cells and changes in suspension stability (V.S.). Cutaneous immunological tests had been made with filtrates from cultures of various streptococci, with negative results, but further work was eminently desirable.

THE LONDON MEDICAL EXHIBITION.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

(*Continued from p. 895.*)

BOOTS PURE DRUG CO. (Nottingham) had a display of fine chemicals and pharmaceutical preparations, especially prominent being the arsenobenzol preparation approved by the Ministry of Health. Stabilarsan, for vein injection; Sulphostab for subcutaneous and intramuscular injection; and Bismostab, a sterile suspension of pure bismuth in glucose solution. In addition, Hexyl-Resorcinol in special gelatin capsules, liver extract for the treatment of pernicious anæmia, and Ephedrine for use in asthma and hay-fever were prominently displayed. some of them making an imposing show in large vases, while a variety of tablets and pills made an attractive exhibit. Gonococcus vaccines, Chlor-san, a scientifically produced hypochlorite antiseptic which can be used as an oral or a nasal wash and in the bath, a new product, also received attention.—OPPENHEIMER, SON AND CO., LTD. (59, Clapham-road, London, S.W.), had an attractive display of their well-known productions, including Roboleine. a vitamin food with maltose, diastase, nitrogenous and phosphoric compounds; Vitad, a purified unsaponifiable fraction of cod-liver oil; Citragon, for the treatment of gonorrhœa; and therapeutic ointments such as Ung. Renaglandin, hæmostatic and vasoconstrictive, and Ung. Renaglandin anæsthetic, which contains 5 per cent. eucaine lactate.—THE MOND STAFFORDSHIRE REFINING CO., LTD. (Abbey House, Westminster, S.W.), displayed their germicide. for which is claimed complete penetration and harmlessness to tissues with good healing action. Indicated in many skin diseases the preparation is put up *in the form of liquid, ointment*, and capsules for internal use. Throat pastilles, a soap, and a dental cream of attractive flavour are also among the preparations supplied by this firm.—DIMOL LABORATORIES, LTD. (40, Ludgate-hill, London, E.C.), showed their well-known bactericide, which is claimed to be 85 times more efficient than pure phenol. It is indicated in all bacterial invasions of the intestinal tract, does not produce any toxic effect, and is voided with the fæces. The preparation is put up in the form of pulverettes and is prepared as syrup, pastilles, lavage powder, ointment, and as a dentifrice. In the form of snuff it can be supplied in a neat mechanical bottle for the pocket, so that a prophylactic against nasal infection is always at hand. —BRITISH ALKALOIDS, LTD. (104, Winchester House, London, E.C.), demonstrated their T.C.P. (Trichlorophenylmethyliodosalicyl in H_2O) a powerful germicide which is analgesic, antithermic, keroplastic, nonhæmostatic, non-caustic, and non-toxic. Externally it promotes rapid healing and internally administered in the form of a colloidal emulsion it can be used in all forms of hyperchlorhydria, dysentery, enteritis, and arterio-sclerosis.—W. MARTINDALE (12, New Cavendish-street, London, W.) had a wide selection of pharmaceutical preparations very well displayed. *Volume II. of the Extra Pharmacopœia*, the nineteenth, which has just been issued, was frequently examined with approval as it is concerned with developments in investigations, experimental research, and diagnosis, and contains much new matter in connexion with all departments of medicine.—THE PINEOLEUM CO., INCORP. (New York City) (BROOKS AND WARBURTON (40–42, Lexington-street, London, W.)), demonstrated Pineoleum, an anodyne, emollient, and deodoriser having the following composition: menthol, 0·520 g.; camphor, 0·520 g.; ol. eucalyptus and glob., 0·520 g.; ol. Zeyland cinn. (Ceylon cinn.), 0·208 g.; ol. dac. cupr. (oil of pine needles), 1·041 g.; aromatics, qs.; liquid petrolatum, 100 c.cm.—WILCOX, *JOZEAU* AND CO. (51, *Great St. Andrew*-street, London, W.C.) exhibited many different preparations of Lactéol (Boucard), a lactic ferment, including tablets and liquid in ampoules for intestinal treatment, powder for surgical. nasal, and aural treatment, ovales for gynæcological treatment, and suppositories.—SANDOZ CHEMICAL WORKS (5, Wigmore-street, London, W.). Among the wide selection of pharmaceutical preparations exhibited at this stand may be mentioned Calcium-Sandoz, a calcium salt obtained from an oxidation product of glucose containing 13 per cent. of lime which corresponds to 9·3 per cent. of calcium; this may be given orally, intramuscularly, or intravenously; Allisatin Brand Tablets, a new and tasteless method of administering allium sativum; and Belladenal Brand Tablets, analgesic, anticonvulsive, and hypnotic.—EVANS, SONS, LESCHER AND WEBB, LTD. (60, Bartholomew-close, London, E.C., and 56, Hanover-street, Liverpool), divided their exhibit into three sections: (1) biological products, (2) special preparations, and (3) medicated soaps. The second section included Cascaromat, a concentrated elixir of cascara; Purgoids, small white sugar-coated tablets containing a combination of phenolphthalein, aloin, ipecac., and belladonna which are effective without griping; and Maraphos, a tonic food for children after exhausting illnesses.—CHAS. ZIMMERMANN AND CO. (9–10, *St. Mary-at-Hill, London, E.C.)* included in their exhibit Posterisan, a local vaccine from *B. coli communis* in the forms of ointment and suppositories for hæmorrhoids; Bilival "Ingelheim," a gall-stone preventive; Chinosol, a water-soluble non-poisonous antiseptic which does not irritate the skin; and Papain "Dega Brand," a digestive ferment active in any media, acid, alkaline, or neutral.—ROBERTS AND CO. (76, New Bond-street, London, W.) presented a number of useful pharmaceutical preparations, including Ferrigen, iron arsenate in ampoules for increasing the number of erythrocytes in anæmic conditions—this is also prepared with the addition of strychnine sulphate; Robuval, an elixir of *strontium bromide* with an inodorous fluid extract of valerian, a nerve sedative; and Arcolax, specially selected and cleaned seeds of *Psyllium plantago*, for the treatment of habitual constipation.—THE ANGLO-FRENCH DRUG CO., LTD. (238A, Gray's Inn-road, London, W.C.), displayed a number of products of special interest, including Stannoxyl, Mycolactine, Iodobesin, and Orargol. Of particular note were the Bacte-Phages, the therapeutic bacteriophages of Prof. d'Herelle, available in various combinations for the treatment of bacillary dysentery, intestinal, respiratory tract, and purulent infections; Oleoformine, a cholagogue containing in tablet form cholic acid, hexamine, and sodium oleate; and Bakolyre, a solution of amino-acids and creatinin in ampoules for the treatment of tuberculosis and other states of denutrition.—MODERN PHARMACALS, LTD. (2, Calthorpe-street, London, W.C.), showed Tetrasthenol, an organic combination of iron, arsenic, glycerophosphate, and strychnine for subcutaneous injection in the treatment of anæmia, neurasthenia, and debility; Bicam, bismuth camphorate in ether washed olive oil, for the treatment of syphilis; and Sulfarsenol.—THE SACCHARIN

Corporation, Ltd. (72, Oxford-Street, London, W.), displayed Novocain, a local anæsthetic for dental and surgical work; Trevalin, a substitute for morphia free from the toxic effect of morphia on the heart; and Caustiscin, for devitalising dental pulp. It is made in varying strengths to suit individual cases and it is claimed to be quite painless in application, while its use obviates arsenical peri-odontitis.—Bristol Myers Company (112, Cheapside, London). The chief exhibits on this stall were Sal Hepatica, a well-known effervescent laxative which encourages a daily habit by stimulating the biliary flow (it is announced that this preparation is not advertised to the public); Ziratol, an antiseptic of the naphthalene series having approximately three times the germicidal efficiency of carbolic acid while being free from toxic action; and Ipana, an effective tooth paste which contains Ziratol, and thus exercises a germicidal effect, while it hardens spongy and bleeding gums.—Genatosan, Ltd. (Loughborough, Leicester), the makers of Sanatogen, Formamint, and Genasprin, included in their exhibit a full range of detoxicated and ordinary vaccines, including Anti-Coryza Vaccine Spray and an Anti-Diphtheria, Scarlet Fever, and Whooping-cough Spray for producing local immunity during epidemics. Attention was also drawn to Genozo Tooth Paste for the double purpose of beautifying the teeth and saving the gums.

Endocrines, Ltd., and E. H. Spicer and Co., Ltd. (72, Wigmore-street, and at Watford, Herts), showed a wide range of the "Harrower" endocrine preparations including Anabolin for the treatment of high blood pressure and Thymocrin for chronic psoriasis. Among "Homburg" preparations Salvochin and Transpulmin for use in pneumonia were also shown, as well as *B. acidophilus* Emulsion.—Armour and Co., Ltd. (Armour House, St. Martin's-le-Grand, London, E.C.), presented a very attractive display of gland products under the specific name of "Glanoid." Particular attention was called to a concentrated fluid extract of liver, each ounce of which represents 8 oz. of fresh calf liver prepared while containing the natural animal heat.—The British Organotherapy Co., Ltd. (22, Golden-square, London), exhibited a wide range of glandular products, monoglandular and pluriglandular, in the form of Opocaps, soluble capsules for oral administration, and Opojex, ampoules for hypodermic injection. Evatmine for asthma, hay-fever, urticaria, spasmodic affections, and chilblains was also shown, as well as Saccharomycin, a fluid yeast for boils, furunculosis, and acne.—G. W. Carnrick Co. (Brooks and Warburton, Ltd., 40–42, Lexington-street, W.) displayed endocrine products emphasising the fact that only fresh glands from healthy animals are employed and that all desiccations are made at low temperatures in vacuo. Special attention was directed to a liver extract for the treatment of anæmia, to Incretone, a liquid endocrine tonic, and Hormotone for the relief of many distressing symptoms at the menopause.—Crookes' Collosols (22, Chenies-street, London, W.C.) included in their exhibit, among other preparations, Collosol Argentum, Iodine, Calcium, Manganese, and a new combination of petroleum with Collosol Sulphur, presenting a laxative with intestinal disinfectant and deodorant properties.—C. J. Hewlett and Son, Ltd. (35–42, Charlotte-street, and 83–85, Curtain-road, London, E.C.), showed Hæmorrhaline, an ointment for hæmorrhoids, external and internal; Hormonigen, pluriglandular extracts; Mist. Pepsinæ Co. c. Bismutho, a remedy in gastric disorders; and Evapogens, or medicated skin lotions. Surgical instruments, dressings, and sprays were also exhibited. —Petrolagar Laboratories, Ltd. (Braydon-road, London, N.), presented their Petrolagar, an emulsion containing 65 per cent. of pure liquid paraffin and agar-agar, flavoured and palatable. The oil is atomised by hydraulic pressure in which state it is held by agar-agar. The preparation produces a normal soft, well-moulded intestinal mass.—Nujol Laboratories (Albert-street, Camden Town, London, N.W.). The intestinal lubricant, Nujol, was here demonstrated as a rational and efficient method for the treatment of intestinal stasis, as well as Mistol, a combination of menthol, camphor, and eucalyptol with a pure mineral oil for inflammatory conditions of the nose and throat.—The Angier Chemical Co., Ltd. (86, Clerkenwell-road, London, E.C.). Angier's Emulsion, which is petroleum with hypophosphites, is a bland and creamy preparation in perfect emulsion and can be administered in conditions where indicated either undiluted or in any desired beverage. Inquirers were supplied with a well-reasoned pamphlet on coughs and their treatment.—Kaylene, Ltd. (7, Mandeville-place, London, W.). exhibited a colloidally reversible hydrated silicate of alumnia in a state of ultra-microscopical subdivision known as Kaylene, an adsorbent of toxins and the products of putrefactive processes in the stomach and intestines, as well as Kaylene-ol for the elimination of the gastro-intestinal content, and other similar preparations.—Virol, Ltd. (Hanger-lane, Ealing, London). The composition of marrow-fat, glycerin extract of red bone-marrow, malt extract, eggs, lemon syrup. and salts of lime and iron known as Virol received much attention, as did also Virol and Milk in powder form, and Virolax. which is an emulsion of paraffin for use in intestinal toxæmia and its sequelæ.—Bengué and Co., Ltd. (24, Fitzroy-street. London, W.), in addition to Dr. Bengué's Balsam for use in rheumatism. gout, neuralgia, and other conditions, showed Pulmo (Bailly), an organic combination of calcium, phosphorus. and guaiacol for diseases of the respiratory organs, Arhemapecty. a new blood coagulant, Guipsine containing the active principles of fresh mistletoe for arterio-sclerosis, and many other useful preparations.—Dr. Joachim Wiernik and Co. (Berlin) (Coates and Cooper, 41, Great Tower-street, London, E.C.), manufacturers of the "Diwag" medical products, showed Pacyl, a derivative of cholin for administration per os for reducing blood pressure.—The Battle Creek Food Co. (Michigan, U.S.A.) (Coates and Cooper) showed biologic foods, including Lacto-Dextrine, being prepared for changing the intestinal flora by encouraging the growth of fermentative acid-forming bacteria, and Food Ferrin, a new iron food for which is claimed a remarkable efficiency in building up hæmoglobin; The Sicco Chemical Works (Berlin) (Coates and Cooper) exhibited the nutritive tonic food Siccopon. pure hæmoglobin in granule form to which is added lecithin, albumin, calcium lactate, and soluble silicic acid; and Reed and Carnrick (Jersey City, N.J.) (Coates and Cooper), among other preparations, showed Testacoids containing the hormones or antacoids of the testicle and the active principles of the prostate; Pancrobilin for the treatment of constipation and obstipation; and Analeptine for the treatment of rheumatism, gout, and in uric acid diathesis. —Temmler Chemical Works (Berlin) (Coates and Cooper) presented, among other preparations, Brosedan, a bromide bouillon indicated in epilepsy, extract of pine needles for bath treatments, and anti-conceptive tablets.—The Denver Chemical Manufacturing Co. (London, E.) showed Antiphlogistine, for which the properties are claimed of continuous application of moist heat, osmosis, and a power of stimulating the cutaneous reflexes to assist in maintaining the blood and lymph circulation of the part affected while hastening the elimination of toxins.—BiSoDol, Ltd. (12, Chenies-street, London), exhibited an antacid-digestive under their trade name intended to re-establish the normal alkalinity of the body without danger of systemic disturbance. It contains bismuth subnit., magnes. carb., sodium bicarb., carica papaya, diastase, and ol. menth. pip.

(To be concluded.)

Holloway Sanatorium.—Lady Midleton, chairman of the Surrey County Nursing Association, recently opened a nurses' home in connexion with the Holloway Sanatorium at Virginia Water. It is a detached building with rooms for 75 nurses, and has cost £35,000.

WHAT BECOMES OF MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—The consternation with which Dr. Graham Little was filled at getting to grips with the subject of his lecture on The Health and Conditions of Work of Medical Students was in some respects an unnecessary emotion. Some years ago I analysed the lives and subsequent histories of the students at St. Thomas's Hospital over a period, and my paper was published in the *St. Thomas's Hospital Gazette*. Sir Squire Sprigge has done the same with regard to a large group of the students at St. George's Hospital.[1] Sir James Paget had previously traced the fate of a large number of St. Bartholomew's students, and with those figures alone was Dr. Graham Little familiar.—I am, Sir, yours faithfully,

EDRED M. CORNER,
Consulting Surgeon to St. Thomas's Hospital.
Beaconsfield, Bucks, Oct. 24th, 1929.

THE NATURE OF BACTERIOPHAGE

To the Editor of THE LANCET.

SIR,—The annotation entitled A Polyvalent Bacteriophage in your issue of Sept. 21st (p. 621) contains several statements which merit some discussion. To begin with, the title itself is subject to criticism. In spite of our lack of knowledge of the nature of the principle, it must be admitted that its action is more in the nature of a virulence. Valence applies only to the degree of combining power of an element or radical. Its biological use is not only rare but does not apply to the action of bacteriophage. Furthermore, the term polyvirulent has found favour among authorities on this subject. In a recent issue of the *Journal of the American Medical Association* an editorial appeared entitled Bacteriophagy as a Therapeutic Agent. Bacteriophagy is the name of an action and not of a substance. This tendency to misuse the terms applied to a now well-known principle is but an indication of the superficiality of the consideration given to a phenomenon, which may be considered as the outstanding contribution of a generation to the sciences of bacteriology and immunology.

Your annotation states "if the bacteriophage will act as a destructive agent of these organisms in vivo the discovery is of immense importance." It has been repeatedly demonstrated that bacteriophage will produce lysis in vivo, hence it may be admitted that the discovery is of immense importance. Does this provoke a widespread willingness to give the principle adequate clinical trial? The annotation further bewails the failure of investigators to perform the clinical experiments which "should not be difficult to devise." Those who have attempted to prove the theories which offer such exceptional promise for the therapeutic value of bacteriophage have not found it impossible to devise adequate experiments. The difficulty has been, and still is, to obtain the necessary clinical material. I venture to state that if any individual or organisation will furnish the opportunity and the means to carry on investigation of the type indicated the answer will not be difficult to obtain nor long delayed. In view of the unusual theoretical considerations, it would seem that the world is a bit slow in seizing the opportunity which has so long been waiting. I have previously expressed the opinion that the explanation for this tardiness lies in the fact that bacteriophages at present available are, for the most part, active against bacteria which do not produce epidemic diseases. This is only true to a limited extent. The problems of cholera and dysentery supply the lack. Such infections, however, are a serious problem only in countries where investigative work on bacteriophage is limited or absent.

There is another factor related to the bacteriophage problem which has been emphasised, as yet, only by myself—namely, the rôle of the bacterial proteins present in bacteriophage filtrates. It is not out of place to point out that bacteriophage as now used contains substances (bacterial proteins) which in themselves, on theoretical grounds, should prove, perhaps, even more effective than the bacteriophage itself. There is much to criticise in the therapeutic experiments thus far performed aside from the failure to provide adequate controls. The fact that any success, however apparent, has attended the use of bacteriophage is in itself an indication of its tremendous potentiality. There is nothing to indicate the size of the dosage nor the method of administration except some undependable therapeutic trials. It has been sufficiently demonstrated that dosage and method of administration are factors intimately concerned with the success of the treatment.

Finally, it may be argued that animal experimentation should provide an answer for some of these perplexing questions. This indeed might prove to be the case could there be found a naturally infectious animal disease of well recognised ætiology against the causative agent of which a bacteriophage was available. Such diseases have been found, but d'Herelle has been practically alone in investigating them. His results merit greater consideration. In the absence of suitable infections in laboratory animals it might be pointed out that where such diseases as cholera, plague, and dysentery occur on a large scale; where the only hindrance to clinical experiment is lack of funds and possibly of organisation; and where the proposed therapeutic agent has been repeatedly shown to be innocuous, there is no logical objection to applying the method. Those workers who have had the vision to carry on the work of bringing recognition to what promises to be an effective agent for the control of infectious disease only ask for an opportunity to provide the controlled experiments that the acceptance of the method demands.

I am, Sir, yours faithfully,

N. W. LARKUM,
Immunologist, Michigan Department of Health.
Oct. 3rd, 1929.

ASPIRATION DURING TONSILLECTOMY.

To the Editor of THE LANCET.

SIR,—In an annotation which appeared in your issue of Oct. 12th (p. 784) mention was made of the possibility of pulmonary infection caused by aspiration during tonsillectomy under general anæsthesia. This prompts me to accentuate the importance of posture during and after the administration of an anæsthetic. The possible danger of inhalation of blood and septic matter from the mouth through the epiglottis should be borne in mind, whether the case be one of general surgery or one concerning the various regions of the mouth alone. *It would be best if the patient were* never allowed for more than a few minutes to be flat on his back with his face to the ceiling, unless this position is imperative from the surgeon's point of view.

In the induction stage the patient will soon be sufficiently subjective to allow his head to be turned well to one side, and so obviate by gravitation the collection of fluid in the epiglottic region. This position is easily maintained without the use of a pillow for most operations, and in those on the mouth the patient's shoulders, after induction, should be raised sufficiently high on a sand-bag to necessitate a well-arranged and suitable hyperextension of the head to gravitate blood and debris immediately into the inverted upper posterior nasopharynx. This leaves the region of the epiglottis clear of blood and saliva, while any excess of fluid can be swabbed out by the surgeon or his assistant from time to time, or by a suction apparatus if preferred, though this procedure is noisy and otherwise unpleasant.

---

[1] THE LANCET, 1905, i., 695. The name of the hospital was not given at the time.—ED. L.

After operation there should be no pillows used, nor should the position be any but the lateral with the head well hyperextended until vomiting or coughing occurs. After this the patient will not be liable to inhale any matter into his trachea. In transit from the operating theatre the patient should always be carried feet foremost if he is to be taken upstairs, and head downwards if going downstairs, for the same reason of keeping fluids and debris gravitating away from the region of the epiglottis, and also for maintaining by gravitation a good blood-supply to the reflex centres. There is no apparent reason why the lateral position with hyperextension of the head and the use of no pillow should not be insisted upon, even in abdominal operations, the sitting-up position being substituted within 20 minutes or half an hour of the operation

I am, Sir, yours faithfully,
JOSEPH BIRT.

St. James' Court, Buckingham-gate, S.W.,
Oct. 18th, 1929.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—Accompanying a prospectus of a company formed, or about to be formed, for treatment centres for Electrotherapy, Physiotherapy, X ray diagnosis, &c., was a letter said to be addressed to the medical profession. On the back of that letter were two quotations from articles I had written, one in *The Lancet* of March 3rd, and the other in the *British Journal of Actinotherapy*. The use of my name is entirely unauthorised, and I have written to the secretary of the company protesting strongly against the publication of my name without my consent. I am, Sir, yours faithfully,
F. HOWARD HUMPHRIS.

Great Stanhope-street, Park-lane, W., Oct. 23rd, 1929.

THE MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LIMITED.

To the Editor of THE LANCET.

SIR,—Dr. Harvey Hilliard's letter in your issue of Oct. 5th (p. 744) raises an ethical question which should receive the careful consideration of all members of this Society.

First: Dr. Hilliard says, "Three important resolutions, of which due notice has been given, are to be moved at this meeting, but have been withheld from the agenda on the notice calling this meeting." In the report of the meeting in your issue of Oct. 12th (p. 798) I see that when Dr. Hilliard sent these to the office to be placed on the agenda of the meeting he was informed that they were matters arising out of the report and need not therefore appear on the agenda, a procedure approved by the legal advisers to the Society. Whether legal or not, surely it is not in the best interests of the Society as a whole that the motions of a member should be withheld in this way. Some might even consider it scandalous.

Secondly: As Dr. Hilliard points out, the board last year decided that they would not be justified in spending the Society's funds in sending out proxies to ensure the re-election of the directors retiring by rotation. They cannot, therefore, logically justify themselves for issuing proxies at the Society's expense this year. Their action in doing so is also the more unfortunate in that one of the motions was one fixing an age-limit of 65 years for directors. If this motion had been carried, four of the seven members of the board would have to retire. On the face of it, therefore, it might be interpreted as a deliberate attempt to keep themselves in office.

The resolution was withdrawn by the mover, Dr. Harvey Hilliard, who stated at the meeting that in his opinion the board had obtained their proxies under false pretences. He would not, therefore, submit his motion to what he considered an unfair vote.

No one would question the right of a board to issue proxies to protect itself as a whole against some attack upon its policy. If, on the other hand, the proxies were sent out to protect the interests of individual members, it is a volte face from the decision of last year.

If this practice is to continue, it seems that the average private member of the Society will never be able to contest the seats vacant upon rotation, because in his case he will have to finance the heavy expense necessary to obtain proxies, whereas the retiring members would be in the comfortable position of having their expenditure met from the Society's funds. Furthermore, the irony of the situation is that the board, in using the Society's funds is, in fact, using in part the candidate's own money deposited with the Society, to contest his election.

For this reason Mr. Steadman's candidature was not pressed to a poll, although he had received over 300 proxies. As one of his supporters, I do not feel that he received fair treatment.

I am, Sir, yours faithfully,
C. BOWDLER HENRY.

Harley-street, W., Oct. 22nd, 1929.

VACCINATION OR INOCULATION AGAINST SMALL-POX?

To the Editor of THE LANCET.

SIR,—In September, 1923, I vaccinated 285 persons (many of them under 18) with the same Government lymph with no ill-results, but the 286th (a girl of 15 years of age) died from encephalitis 15 days after a perfectly normal primary vaccination. The Committee on Vaccination, appointed by the Ministry of Health in 1926, have shown that vaccine virus is present in some brains of post-vaccinal encephalitis, but whether it is associated with some other agent is not quite clear at present. Yet the fact that the vaccine virus has been isolated from some brains of those who have died from post-vaccinal encephalitis naturally raises the question of the danger of using a living virus in vaccination work.

The recommendation of the Committee that vaccination shall be in "one insertion with a minimum of trauma" instead of four insertions has been adopted and recommended by the Minister of Health. It *may* be that this will diminish the risk of post-vaccinal encephalitis, and it would be interesting to know what are the statistics in America where this has been the practice for years, but one is inclined to query the advisability of using a *living* virus at all. We should hesitate to use living staphylococcus or streptococcus however dilute even in one insertion. In the summary of the Committee on Vaccination it is suggested that further research is desirable in exploring the possibilities of the use of a still further attentuated or of a killed virus as an immunising agent. It would be a great relief both to the community and to vaccinators if a killed virus was available for inoculation in place of the living virus as used in ordinary vaccination.

May I ask, through your columns, whether any experiments have been or are being done with the killed virus of vaccinia. Is it possible to produce immunity against small-pox by inoculation of a killed virus?—I am, Sir, yours faithfully,

Oxford, Oct. 26th, 1929. HENRY T. GILLETT.

⁎⁎ Post-vaccinal encephalitis is rare in the United States; our correspondent remarked a fortnight ago that only four cases had been reported. Little has been published on the use of killed vaccinia virus as a prophylactic; the results of its use so far seem to have been almost negative, and nothing encouraging has come from the more recent attempts. It is true that preventive vaccines of some other viruses have proved effective experimentally even when the vaccine has been made from virus which has been killed. In some cases, too, a killed vaccine has proved effective in practice when a dose of living virus has been given subsequently and a mild attack of the disease has thus been induced. In some infections including rabies, distemper, foot-and-mouth disease, and fowl plague, a killed vaccine has by itself conferred immunity, but only for a short time. It may be added that a stock of real small-pox virus would be difficult to obtain, and it would need to be free from other chance human diseases.—ED. L.

CONTAGIOUS ABORTION.

To the Editor of THE LANCET.

SIR,—Several references to contagious abortion in cattle and man are found in your recent issues. Rather less than 20 years ago, I think it was, this disease caused dire losses among dairy herds in parts of New Zealand. The United States had suffered previously and from there much instruction was available. It became recognised that an important contributory factor to the disease was insufficient provision of winter feed, leading to debility in the mother just when the calf in utero was making full demands on her constitution. Your authorities emphasise the digestive route of infection; it is an obvious route, but I question whether, once the disease is introduced to the herd, coitus may not be a method of transmission also.

About sixteen years ago in the Auckland province I attended a young primiparous woman for abortion. Her husband was slaughterman in a local butchery, and I knew that a large proportion of the beasts dealt with by him were cows fattened in consequence of sterility, proved or anticipated, following contagious abortion. As there was no other ascertainable cause for abortion in the fairly advanced stage of pregnancy of the patient, I attributed it at the time to contagious abortion transmitted from the cows through her husband. *I had no reason to suppose him to be* constitutionally affected by the disease.

I may add that the epidemic did good in bringing about a general improvement in method of winter feeding of dairy stock, and the disease is now a much less serious factor than at that time. A chair and teaching to exploit the relationship in disease of man and the lower animals would, I believe, prove of unimagined importance, and lead to wide revision of our social and sanitary methods and new angles of prevention and treatment.

I am, Sir, yours faithfully,
A. H. HALLEN, M.D. Edin.
Alexandra-road, South Hampstead, N.W., Oct. 27th, 1929.

THE BROWN v. WHITE BREAD CONTROVERSY.

To the Editor of THE LANCET.

SIR,—As one of the protagonists of whole-meal bread might I suggest that the Medical Research Council finance another series of tests on the respective values of whole-meal and white flour. In this series let the experimenters use a diet similar to that on which millions of our poorer workers in the industrial and mining centres seek to exist. Those who conducted the demonstration on the values of artificial sunlight at the Mansfield Colliery inquired into the feeding habits of the pit boys, and were amazed at the few who ever had fresh vegetables or fruit, *the main articles* at each meal being white bread, margarine, and tea.

It is well known to all interested in social welfare work that the expectation of life and freedom from disease are very great amongst agricultural labourers, and it is equally appreciated that they have an abundance of Nature's foods. On the other hand, the majority of poorer workers in our crowded areas *have very little fresh vegetables or fruit*, the bulk of their diet being white bread and preserved foods, all deficient in vitamins. When we reach a stage in which they are able to secure such a varied dietary as the one on which Dr. Hartwell and Prof. Mottram fed their rats, we shall not have the same anxiety as we have to-day about their feeding; but till that fortunate day arrives, I am of opinion that legal action should be taken to ensure that the poor shall have bread in the condition our ancestors were able to obtain it—i.e., with the most valuable vitamins and minerals still in it. I am also certain that the results of the experiment I suggest will prove on the side of brown bread.

I am, Sir, yours faithfully,
BRUCE BRUCE-PORTER.
Grosvenor-street, W., Oct. 26th, 1929.

To the Editor of THE LANCET.

SIR,—*There are many like myself* convinced believers in the superior nutritional value of whole-meal flour from clinical observation, who must feel sceptical as to the validity of the conclusions drawn by Prof. Mottram and Miss Hartwell from the recent experiments reported in your issue of Oct. 26th. It is surely an accepted fact by all students of nutrition that the various vitamins can only function adequately when the *general balance* of vitamins and other food factors is correct. In these experiments the test diets are, by their own showing, defective on other grounds, and therefore it would seem that the addition of vitamin B to one of them could not be expected to effect any improvement. The absence of a sufficiency of vitamin A alone would deter normal growth and seriously affect the health of the animal.

I venture to hope that experts who hold opposing views to those of Mottram and Hartwell will feel inclined to give the profession their views on these experiments. The clinicians are looking in vain for definite guidance on this vexed question.

I am, Sir, yours faithfully,
S. HENNING BELFRAGE.
Gloucester-place, W., Oct. 29th, 1929.

CLEAN SWIMMING BATHS.

To the Editor of THE LANCET.

SIR,—Belated though it is I greet with pleasure the report of the Ministry of Health on the Purification of the Water of Swimming Baths, which you annotated last week. I regret, however, that no mention has been made in the report of the strenuous, difficult, and prolonged pioneering work carried out at Poplar for over 20 years. Special reports of this work were always forwarded, in accordance with legal requirements, to the Ministry of Health, and it is these which, without doubt, form the basis of the report just issued.

I am, Sir, yours faithfully,
FREDK. WM. ALEXANDER,
Formerly Medical Officer of Health,
Oct. 26th, 1929. Metropolitan Borough of Poplar.

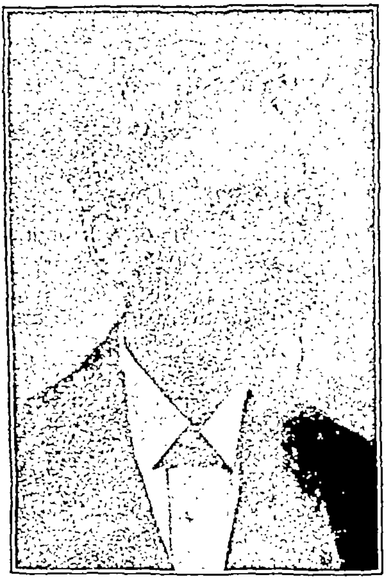
DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION.—The opening meeting of the session of this Association was held on Oct. 19th, when the President-elect, Prof. J. Brontë Gatenby, delivered an address on Radium, X Rays, and the Cell. He gave a careful survey of the knowledge of the action of rays on the cell, and related the results of experimental work done in his own laboratory. Prof. John Joly, F.R.S., gave an account of the pioneer work done in Dublin by the use of hollow needles containing radium or radium emanation in treatment, and described recent developments in needle technique. Dr. R. J. Ludford described his work at the Imperial Cancer Research laboratories on the cancer cell. Dr. W. C. Stevenson, Prof. M. R. J. Hayes, Sir William Wheeler, Prof. L. Abrahamson, and Prof. T. G. Moorhead spoke of the several applications of radium and other rays in medical and surgical treatment.

Obituary.

WILLIAM BEVAN-LEWIS, M.Sc. LEEDS, M.R.C.S., L.S.A.,

LATE DIRECTOR OF THE WEST RIDING HOSPITAL, WAKEFIELD.

WE regret to announce the death of Dr. William Bevan-Lewis, the well-known authority on mental disease and its pathology, which occurred on Monday, Oct. 14th, at Cardigan, in the eighty-third year of his age.



DR. BEVAN-LEWIS.

William Bevan-Lewis was the son of William T. Lewis, of Cardigan, in which city he was born in 1847, and received his early education. In 1864 he joined the medical school at Guy's Hospital, where, among the prominent members of the staff were then Sir William Gull and Henry Cock, while Wilks, Pavy, and Bryant were junior members. Bevan-Lewis was a distinguished student, being a prize-man throughout his career in the preliminary scientific and clinical subjects, and had to wait until his arrival at the age of 21 before he qualified in 1868 as M.R.C.S. Eng. and L.S.A. He would no doubt have gone far, both in professional and academic life in the metropolis, if an early marriage had not determined his choice of immediate private practice. In 1875, however, an opportunity came to him to pursue scientific studies towards which he had a particular impulse rare in those days, for few medical men half a century ago could have regarded an appointment at a lunatic asylum as offering great scientific opportunities. But with this view Bevan-Lewis, at the age of 28, joined the medical staff of the West Riding or Wakefield Mental Hospital, an institution which had been established some 60 years, and which had already obtained a reputation for the psychological study of its inmates. The medical school at Leeds was only ten miles away, and at Wakefield Ferrier did much of the work which resulted in the publication of his experimental researches in cerebral physiology, while Clifford Allbutt also studied there with fruitful result. Further, two of Bevan-Lewis's predecessors at Wakefield had been distinguished for their scientific output in relation to insanity—namely, the late Dr. H. C. Major, whose work on the histology of the brain in the insane was of real importance both in accomplishment and suggestion, and Sir James Crichton-Browne, the veteran psychologist. In going to Wakefield, therefore, Bevan-Lewis was treading in distinguished footsteps, and he was immediately confirmed in the career which he had adopted. He rose rapidly, first to be pathologist to the hospital, then to be deputy superintendent, and in 1884 he became medical director of the institution. This post he did not resign till 1910, thus completing 35 years of service, 26 of which were spent in the position of the highest responsibility.

Of Bevan-Lewis's ideals as to what such a post as medical superintendent of a large asylum should mean, there is no doubt alike from the results of his work and the recollections of the many who worked with and under him. From each and all there emerges the same picture of a man whose heart was in his researches, and whose inclination directed him towards the teaching and writing of the knowledge which he had to deliver, but conscientiousness and discrimination alike urged him to devote attention to the organising side of his duties. For he knew that if the advancement of psychology and pathology in relation to insanity were to be obtained, the sure way would be by the intimate study of the subjects of investigation placed beneath his hand. Hence the administrative side of his work was fruitful, including the starting of an out-patient department (then quite a novelty), the reconstruction of the pathological laboratory, the provision of separate wards for the treatment of imbecile cases, and the institution of a well-equipped block for the reception of early cases of mental disease.

While these things would have been sufficient to secure for Bevan-Lewis a high position in his specialty, his memory will be better preserved by his writings and teachings, which expressed the results of his personal and assiduous researches. He was for 25 years lecturer and examiner in mental disease at the University of Leeds, succeeding Crichton-Browne and Major in this post, which later, on the rise of the Leeds school of medicine into a University Faculty, became a professorship. In 1889 he published his well-known text-book of mental diseases, in which he proposed to record the existing knowledge of the pathological aspects of insanity. In this exhaustive work he was stimulated and supported not only by a recurrent staff of interested fellow-workers, but by the presence, as visitors to Wakefield, of a constant influx of young collaborators. This work was recognised on its appearance as practically the first attempt to present in the field of English psychological medicine a résumé of our knowledge of morbid changes in the brain of the insane. It was founded largely on original research, and illustrated with exceptionally good plates, and it was seen at once to supply defects in the treatises, for example, of Bucknill, Tuke, and Clouston. The book was reprinted ten years later, and, although in certain respects the contents were modified, its individual character remained, and this to such an extent that it was easy to hold that work done by others during the interval had not been sufficiently taken into account. But the author's scheme of presentation was simple and serviceable from a psychological standpoint, while, as a matter of fact, certain of the main theories as to minute structure which, when first made seemed to be incompatible with results obtained by experiment, have been since demonstrated by Sir Charles Sherrington and his followers as accurate. Thus and for nearly 30 years Bevan-Lewis had the satisfaction of coming into his own.

Prof. J. Shaw Bolton, Medical Director of the West Riding Hospital, writes:—" I feel doubtfully qualified to write even a brief psychological sketch of the great neurologist whom I succeeded at Wakefield Mental Hospital 19 years ago, for I saw Bevan-Lewis on the day of my election and on no other occasion. I remember vividly my interview with him in his drawing-room, now a dormitory of the institution. He was not in the least the man I had often pictured to myself during the 20 years I had been familiar with his work and reputation, and whose beautiful drawings of the cortex cerebri had first attracted my attention to neurology. He was quiet, dignified, and reserved, and though perfectly courteous, neither volunteered nor provided any information of value regarding the institution and my new duties. I could fully appreciate his point of view. I was a stranger about to undertake the work he was laying down and of which he was jealously proud; and his main object was to obtain the best terms possible for the staff he was leaving behind him. I parted from him with regret, feeling certain that I should never see him again. I wrote later asking if I could come over before he left Wakefield, but he replied that it was not necessary and that I should find everything in perfect order. A lengthy residence in Wakefield has satisfied me of the truth of this description of a mere interview as a picture of the mentality of Bevan-Lewis. He was an enthusiast, and a recluse with few interests beyond his scientific investigations. He was retiring and aloof, and rarely to be seen or interviewed, but this very attitude towards others, which might have led lesser men to be ignored, in the case of Bevan-Lewis was a powerful factor in the success of his administration. For he was successful, and during his 26 years as medical director he saw, and took a prominent part in, administrative changes and extensions which taken alone would have gained him a high reputation. He witnessed the opening of Menston and Storthes Hall Mental Hospitals, and the planning, building and early years of working of a new mental hospital attached to the Wakefield Asylum of old. He held views on mental hospital evolution which were almost prophetic. As early as 1889 he founded at Wakefield an out-patient department which is still flourishing, and during many years, until in fact the opening of Scalebor Park Mental Hospital rendered the step unnecessary, he provided private mental nurses to the district. Referring in 1889 to the proposal, under the auspices of the London County Council, to erect an acute hospital, providing accommodation for 100 patients, to appoint a staff of experienced visiting physicians, and to establish in connexion therewith a school for the scientific study of mental disease, he remarked:

> 'It must be admitted that the tendency to the establishment of the hospital system is the correct one, and that this end will be eventually realised. Within the metropolitan area the conditions are so peculiarly favourable to its development that one is surprised at the limited accommodation proposed by its advocates; *but as applicable to the provinces*, the difficulties of applying the system are obvious, and a modified procedure is necessarily demanded. That the large country asylums should eventually become receptacles for the hopelessly incurable chronic class, officered and managed upon a far more economical system than the present; that special hospitals for dealing with the acute insane, with a well-trained staff of experienced alienists, and affording facilities for a development of clinical teaching should be instituted; and that they should contain centres for scientific investigation and research, are facts so self-evident as to require no further emphasis here.'

"These views found expression in Bevan-Lewis's administration during the next 20 years. He left the chronic block as he found it, an antiquated building surrounded by high walls, and it is doubtful whether he even noticed its sanitary defects, so endeared to him was every brick of Wakefield. In 1900, however, he witnessed the opening of the acute hospital, a modern building replete with what were at that time unique means for research and methods of scientific treatment. This hospital contained a large lecture hall and library and several laboratories, and it possessed extensive provision for electro- and hydro-therapeutic methods of treatment. I believe that to a great extent the new hospital realised Bevan-Lewis's ideal, although its completion came too late to enable him with his enfeebled health adequately to administer it. Bevan-Lewis lived and worked in a world apart, and if he felt and resented the belated recognition accorded to his work on cortical localisation no one knew it. He justly acquired a great scientific reputation, and his position as a neurologist of the highest rank is now at its acme, when it is universally acknowledged that much of his best work waited for a quarter of a century for confirmation and acceptance."

In 1909 Dr. Bevan-Lewis was president of the Royal Medico-Psychological Association, but otherwise, owing partly to early want of recognition and partly to his own retiring disposition, he escaped all public acknowledgment for his valuable services to science and society. He received his reward, and to him it appeared a satisfactory one, in the grateful regard which he obtained from pupils, many of whom became well known and successful in their careers. Throughout his work at Wakefield he was assisted by a devoted wife, Rose Eve, the eldest daughter of Mr. W. C. Kaye, of Enfield, whom he had married when he was only 23 years of age. The loss of his wife occurred some years after his retirement from Wakefield, and was one from which he never recovered. He had no children.

THE NEW TREATMENT FOR BURNS.

A REPORT ON TANNIC ACID.

MANY substances have been used for burns since the time when carron oil was discarded from domestic medicine cupboards. The search has always been for an easily applied dressing that will not only relieve pain and mitigate shock but will have some antiseptic properties and will not require frequent changes. The substances found to have at least some of these desirable qualities vary widely, not only in composition but in physical properties. Among these powdered sodium bicarbonate, ointments spead on lint, paraffin wax applied with a spray, and liquids such as picric acid have had their supporters. It seems probable that these applications will all be replaced as routine methods of treatment by the use of tannic acid, the introduction of which is described by the Medical Research Council as "one of the most important recent advances that have been made in modern therapeutics."[1] Since Dr. E. C. Davidson, of the Henry Ford Hospital in Detroit, first advocated this method four years ago,[2] we have had evidence from various sources substantiating his good results.[3] These have now been confirmed by Mr. W. C. Wilson, *who is able to report a consecutive series of 117 cases* treated by this method in the department of surgery of the University of Edinburgh. The death-rate from all causes in this series was 11·1 per cent., the mortality in 105 children under 10 years of age being 10·5 per cent. compared with 38·7 per cent. in a series of comparable cases treated by other methods. The tannic acid is used in aqueous solution, which should be freshly prepared for each case (though not necessarily for each application), since after some weeks tannic acid in solution is changed to gallic acid, which has no power to coagulate protein.

The strength recommended is a 2·5 per cent. solution in warm sterile water, sprayed on the affected area, which has been gently cleansed with ether under a general anæsthetic, preferably gas and oxygen. An ordinary nasal spray atomiser can be used and the parts dried by means of electric lamp bulbs in the bed-cage or by a current of hot air from an electric drier. Spraying and drying are carried out at intervals of one hour till the parts are covered with a thin brown layer of coagulated tissue. This usually appears in burns of the second and third degrees after from 8 to 12 applications. In deeper lesions, and also when there is much exudation of serum from the raw surface, further applications may be required to procure a satisfactory coagulum. There is no danger of a too deep corrosive action when a weak solution is used.

In burns of the face the eyes, nostrils, and external auditory meatus are protected with moist wool during spraying.

Local Effects after Treatment.

After the first few applications pain is relieved and disappears. The parts rapidly become insensitive and subsequent spraying causes no discomfort.

---

[1] The Tannic Acid Treatment of Burns. By W. C. Wilson. Medical Research Council, Special Report Series No. 141. London: H.M. Stationery Office, 1929. Pp. 31. 1s.

[2] Surg., Gyn., and Obstet., 1925, xli., 202.

[3] See THE LANCET, 1925, i., 330 and 351.

The thin brown leathery coagulated layer can be handled freely without risk of conveying infection to the underlying tissues, and its rigid splint-like character ensures the best conditions for the healing processes beneath it. In uncomplicated cases the coagulum should be left until it peels off readily, which it will do within two or three weeks in lesions of the second or third degrees. Areas still uncovered by epithelium are protected by sterile vaseline applied on strips of gauze.

Sepsis.—When sepsis is suspected, from the reddening of the surrounding skin or from the presence of a little sero-purulent discharge from the edge of the coagulum, no special treatment is necessary if the patient's general condition remains satisfactory. Gross infection, which rarely occurs except in association with the formation of sloughs in deep burns, leads to the formation of a collection of pus. The coagulum is pushed up by this pus and can usually be stripped off easily; if it continues to adhere firmly it can be cut away with scissors. In no circumstances should wet dressings be applied over the coagulum.

The provisional instructions for the first-aid treatment of burns by tannic acid will be set out in our columns next week.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 19TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 154 (last week 131); scarlet fever, 3549; diphtheria, 1582; enteric fever, 140 (last week 104); pneumonia, 1042; puerperal fever, 53; puerperal pyrexia, 124; cerebro-spinal fever, 6; acute poliomyelitis, 23; acute polio-encephalitis, 2; encephalitis lethargica, 9; continued fever, 1; dysentery, 10; ophthalmia neonatorum, 112. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Oct. 22nd–23rd was as follows:—Small-pox 168 under treatment, 0 under observation (last week 166 and 3 respectively); scarlet fever, 2464; diphtheria, 2242; enteric fever, 69 (last week 39); measles, 186; whooping-cough, 131; puerperal fever, 23 (plus 13 babies); encephalitis lethargica, 126; poliomyelitis, 8; "other diseases," 20. At St. Margaret's Hospital there were 16 babies (plus 8 mothers) with ophthalmia neonatorum.

Of the notifications of enteric fever, 30 were received from the County of London—namely, Hackney, Islington, Lambeth, Paddington, St. Marylebone, Wandsworth, and Westminster each 1, Stepney 2, and Lewisham 21.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 7 (3) from enteric fever, 14 (0) from measles, 8 (2) from scarlet fever, 13 (1) from whooping-cough, 31 (6) from diphtheria, 136 (35) from diarrhœa and enteritis under two years, and 40 (7) from influenza. The figures in parentheses are those for London itself.

Deaths from diarrhœa are now definitely on the decline, the highest figures being reported from Liverpool 11, Birmingham 9, and Leeds 5, while Glasgow and Dublin report 8 each. The deaths from enteric fever outside London were reported from Bournemouth, Bristol, Salford, and Leeds 1 each; the 4 deaths in London occurred at Lewisham, where the outbreak to date (Oct. 29th) amounts to 64 cases with 5 deaths.

The number of stillbirths notified during the week was 257 (corresponding to a rate of 39 per 1000 births), including 48 in London.

VETERINARY RESEARCH AT LIVERPOOL.—The University has received £10,000 for research to be conducted under the direction of the William Prescott Professor in the Department of Veterinary Pathology. This sum represents contributions of £6000 and £3000 from two anonymous donors, and £1000 from Messrs. R. Silcock and Sons, Ltd., of Liverpool.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

REASSEMBLY OF PARLIAMENT.

BOTH Houses of Parliament reassembled for the autumn session on Tuesday, Oct. 29th. The Government have in hand a considerable programme of legislation which they intend to pass before the Prorogation next July. Among the more important Bills are two dealing with Slum Clearance and Reform of the Factory Laws. These measures are likely to be introduced before Christmas, but it will depend upon the progress made with other Bills whether they proceed any further before the reassembling of Parliament early in the New Year.

The Government's Programme.

Mr. SNOWDEN, in announcing the Government's programme of business, said that it was proposed to proceed with the Unemployment Insurance Bill before the Christmas adjournment. It was hoped to make progress with other measures foreshadowed in the King's Speech, including the Factories Bill, to regulate hours of industrial employment. The financial resolution in connexion with the Highlands and Islands Medical Services (Additional Grants) Bill would be placed on the Order Paper on the following day, and a White Paper would also be available.

Notices of Motion.

In the ballot for notices of motion Lieut.-Colonel FREMANTLE gave notice that to-morrow week (Nov. 6th) he would call attention to ribbon development and move a resolution. Mr. T. HENDERSON also gave notice of a motion on the nationalisation of water-supply.

HOUSE OF COMMONS.

TUESDAY, OCT. 29TH.

Voluntary Hospitals and Motor Accidents.

Sir WILLIAM DAVISON asked the Minister of Transport whether, in view of the serious cost and difficulties thrown on voluntary hospitals throughout the country in the receiving and treating of persons suffering from motor accidents, and also in view of the fact that in very many cases no payment is made to the hospital in question by such persons for their treatment in the hospital, His Majesty's Government would consider the propriety of raising a central fund by means of a small deduction from driving licences, or otherwise, with a view to adequate payments being made to voluntary hospitals who are unable to obtain payment for services rendered in the case of motor accidents.—Mr. HERBERT MORRISON replied: I do not feel justified in recommending the legislation which would be required to impose a compulsory levy on the drivers of all motor vehicles for this purpose.

Sir WILLIAM DAVISON asked if the Minister of Transport did not recognise the serious position that many hospitals were in by reason of their often keeping a special ward, particularly in the country, to deal with motor accidents which interfered with the normal work of the hospitals, and was a great expense to them, when they were already finding it difficult to pay their way. He also asked if the Minister could not introduce some clause at any rate in the legislation which he had promised with regard to third-party insurance, which would deal with this matter.—Mr. MORRISON replied that they all recognised the financial difficulties of voluntary hospitals, but he was unable to agree that that was a question which exclusively related to the services required from the hospitals by motorists.

Mr. THURTLE asked if one of the remedies in this matter would not be for motorists to take more care.

Mr. ALBERY asked the Minister to consider the propriety of approaching the Automobile Association and the Royal Automobile Club with the suggestion that they should try to devise some means of collecting these sums for the hospitals.—Mr. MORRISON replied that there was no reason to believe that motorists as a class were less generous in their contributions towards the hospitals than any other section of the community, and it would be difficult to single them out from other users of the hospitals.

Mr. LOUIS SMITH asked the Home Secretary if he would obtain information from the police of the country of the number of accidents treated in local hospitals and resulting from the use of motors during the months from April to the middle of October, with the object of ascertaining the burden now placed on those institutions.—Mr. CLYNES replied: I have consulted my right hon. friend the Minister of Health, and am advised that the collection of the figures the hon. Member mentions would not secure the object he has in view; and as the figures could not be obtained without imposing great labour on the police, out of all proportion to the usefulness of any results that can be anticipated, I regret that I do not see my way to ask the police to furnish them.

Government and Slum Clearance.

Lieut.-Colonel FREMANTLE asked Mr. Snowden, Chancellor of the Exchequer (who is acting for the Prime Minister) whether the much-promised measure for slum clearance was included in what the right hon. gentleman called "minor *Bills*," or if it was not considered of sufficient importance to be introduced before Christmas.—Mr. SNOWDEN replied that he certainly would not include the Slum Clearance Bill among the minor measures to which he had referred. He hoped that when the Bill was introduced it would be recognised that it was a Bill of first-rate importance. The programme which the Government had outlined, and which they hoped to get through with the assistance of the Opposition, so far as their proposals met with approval, was rather ambitious. He could assure the House that the Slum Clearance Bill would be taken as soon as Parliamentary time permitted.

Procedure at Coroners' Inquests.

Sir KINGSLEY WOOD asked the Home Secretary whether he was aware of the considerable public apprehension concerning the recent conduct and procedure of certain coroners' inquests, particularly in relation to the ancient and well-established rights and liberties of the subject, and whether he could make any proposals or statement to the House on the matter.—Mr. CLYNES replied: I am obliged to the right hon. gentleman for his courtesy in giving me long notice of this question, and thus affording me the opportunity of consulting with my noble friend, the Lord Chancellor, and my hon. and learned friend, the Attorney-General, upon the legal aspects of the matter. As the right hon. gentleman is no doubt aware, the law relating to coroners' inquests was revised and brought up to date by a comprehensive measure passed only three years ago. The view in which the authorities I have consulted concur is that it would be a mistake so soon after the revision of the law to consider making another fundamental alteration because of what has happened in one or two quite exceptional cases. The provision under which coroners pursue their inquiries up to the point of enabling the jury to find the persons, if any, who have been guilty of murder or manslaughter, embodies the ancient common law of England. Having regard to the number of inquests held every year—over 30,000 in 1927—the criticisms of the working of this provision have been remarkably few, and, on the other hand, there have been very many cases in which its value has been clearly demonstrated. I propose, therefore, as at present advised, to take no action in the matter.

War Pensioners and Seven Years' Limit.

Mr. DAY asked the Minister of Pensions whether he was now in a position to make an announcement with reference to the Government's attitude regarding the abolition of the seven years' limit with reference to ex-Service men; and whether it was proposed to obtain powers to remove other pension grievances, including the amendments to the final awards regulations in the case of war orphans.—Mr. F. O. ROBERTS replied: I expect to be able very shortly to make a full statement on the point raised in the first part of the question. I am at the same time giving close attention to all difficulties that have been put before me in connexion with the administration of war pensions, and I shall do what is possible from time to time to remedy them.

University Graduates and Choice of a Career.

Mr. GRAHAM WHITE asked the Minister of Labour if she would circulate to the proper authorities at the universities periodical reviews of the various branches of industry and the professions, in order that undergraduates might be enabled to make plans for their future at a suitable time.—Miss BONDFIELD replied: The hon. Member is perhaps aware that my department, in collaboration with the Incorporated Associations of Headmasters and Headmistresses, recently began to issue through H.M. Stationery Office a series of pamphlets on the choice of careers. Copies of these are being sent to University Appointments Boards and to all secondary schools on the "recognised" list of the Board of Education. I will gladly supply the hon. Member with a list of these pamphlets so far as they have been completed, if he so desires.

Administration of the Factory Acts.

Mr. GRAHAM WHITE asked the Prime Minister if it was the intention of the Government to transfer the administration of the Factory Acts to the Ministry of Labour.—Mr. SNOWDEN replied: This matter has not been under the consideration of the Government.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were successful:—

Surgery.—A. Buch and R. F. M. Child, St. Mary's Hosp.; V. J. H. Coldan, Beyrout; R. W. Goldsbrough, Leeds; A. Guirdham, Charing Cross Hosp.; H. C. Haige, St. Mary's Hosp.; G. A. F. Holloway and A. Kellner, London Hosp.; and R. K. Naudiel, Birmingham.

Medicine.—W. T. Ellis, Manchester and Charing Cross Hosp.; W. J. Frith, London Hosp.; A. Guirdham, Charing Cross Hosp.; W. M. Hamer, Manchester and Charing Cross Hosp.; W. St. A. Hendricks and R. J. Kagan, St. Mary's Hosp.; H. W. Maurer, Charing Cross Hosp.; T. M. White, Bristol; and F. A. Yarde, St. Mary's Hosp.

Forensic Medicine.—A. N. De Monte, St. Mary's Hosp.; W. J. Frith, London Hosp.; B. C. Ghose, Durham; R. Gilmore, Manchester; A. Guirdham, Charing Cross Hosp.; W. St. A. Hendricks, St. Mary's Hosp.; G. A. F. Holloway, London Hosp.; C. Hortop and A. D. H. Hugo, Guy's Hosp.; A. Liberis, St. Bart.'s Hosp.; W. McDermott, London Hosp.; J. E. Moody, St. Mary's Hosp.; L. J. Pearson, Birmingham; T. G. Robinson, Guy's Hosp.; L. C. H. Sykes, Leeds; and F. A. Yarde, St. Mary's Hosp.

Midwifery.—M. Asaad and R. F. M. Child, St. Mary's Hosp.; A. Clark, Glasgow and London Hosp.; C. E. P. Davies, Guy's Hosp.; A. N. De Monte, St. Mary's Hosp.; H. R. Fosbery, Middlesex Hosp.; A. Guirdham, Charing Cross Hosp.; J. E. R. Heppolette, St. Mary's Hosp.; G. A. F. Holloway, London Hosp.; D. W. Hoodless, Charing Cross Hosp.; V. J. Lopez, St. Mary's Hosp.; W. McDermott, London Hosp.; L. J. Pearson, Birmingham; and S. Ramadas, St. George's Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and *midwifery*: A. Clark, A. N. De Monte, W. T. Ellis, R. W. Goldsbrough, A. Guirdham, W. M. Hamer, W. St. A. Hendricks, G. A. F. Holloway, C. Hortop, W. McDermott, and T. M. White.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial on Oct. 26th the following diplomas were conferred:—

D.P.H.—H. J. Gibson, *David Lennox, *K. A. T. Martin, Sarup Narain and N. S. Turnbull.

* In absentia.

UNIVERSITY OF SYDNEY.—Dr. H. Whitridge Davies, who for the last three years has been lecturer in physiology and pharmacology in the University of Leeds, has been appointed to the Chair of Physiology at the University of Sydney.

Dr. Davies is an Australian by birth, and is the son of Mr. Harold Davies, professor of music at the University of Adelaide. After graduating at Adelaide, he came to Europe with the Australian Army Medical Corps, and served in France. He subsequently became research assistant to Dr. J. S. Haldane, at Oxford, and in 1921 he worked in the Department of Therapeutics in the University of Edinburgh under Prof. Jonathan Meakins. Later he spent a year at the Rockefeller Institute, New York.

RADIOLOGICAL CONGRESS IN LONDON.—The annual congress of the British Institute of Radiology, incorporated with the Rontgen Society, will be held at the Central Hall, Westminster, from Dec. 4th to 6th. There will be a trade exhibition of X ray apparatus. The Silvanus Thompson and Mackenzie Davidson memorial lectures and other addresses will be given in the Congress Hall adjoining the exhibition.

LORD MOYNIHAN ON VOLUNTARY HOSPITALS.—Speaking at Dewsbury on Oct. 15th, Lord Moynihan said he believed we had now arrived at the most critical period in the history of hospital administration in this country. Hitherto it had required a confession of pauperism to allow a patient to receive benefit from the poor-law hospitals, but under the new Local Government Act the work of all the hospitals could be coördinated, the number of available beds doubled, and the disgrace of long waiting-lists reduced. It was the hope of the medical profession that the standards and ideals of the voluntary hospitals would guide and inspire the work of the old poor-law institutions under the new control. It must be recognised, however, that physicians and surgeons required for the adequate staffing of these hospitals did not at present exist. Special and arduous training was needed before a man could undertake consulting duties, and the responsible authorities must go slowly at first and increase only at the rate at which fully qualified persons became available for the work. General practitioners should be given greater facilities for keeping in touch with their patients under treatment, and for following the practice of the hospitals so as to keep themselves abreast of the advances of medicine. The great imperfection of the National Health Insurance Act from the medical standpoint was that it gave the practitioner no chance of availing himself of hospital practice or of getting post-graduate training.

The thin brown leathery coagulated layer can be handled freely without risk of conveying infection to the underlying tissues, and its rigid splint-like character ensures the best conditions for the healing processes beneath it. In uncomplicated cases the coagulum should be left until it peels off readily, which it will do within two or three weeks in lesions of the second or third degrees. Areas still uncovered by epithelium are protected by sterile vaseline applied on strips of gauze.

Sepsis.—When sepsis is suspected, from the reddening of the surrounding skin or from the presence of a little sero-purulent discharge from the edge of the coagulum, no special treatment is necessary if the patient's general condition remains satisfactory. Gross infection, which rarely occurs except in association with the formation of sloughs in deep burns, leads to the formation of a collection of pus. The coagulum is pushed up by this pus and can usually be stripped off easily; if it continues to adhere firmly it can be cut away with scissors. In no circumstances should wet dressings be applied over the coagulum.

The provisional instructions for the first-aid treatment of burns by tannic acid will be set out in our columns next week.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 19TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 154 (last week 131); scarlet fever, 3549; diphtheria, 1582; enteric fever, 140 (last week 104); pneumonia, 1042; puerperal fever, 53; puerperal pyrexia, 124; cerebro-spinal fever, 6; acute poliomyelitis, 23; acute polio-encephalitis, 2; encephalitis lethargica, 9; continued fever, 1; dysentery, 10; ophthalmia neonatorum, 112. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Oct. 22nd–23rd was as follows:—Small-pox 163 under treatment, 9 under observation (last week 166 and 3 respectively); scarlet fever, 2464; diphtheria, 2242; enteric fever, 69 (last week 30); measles, 186; whooping-cough, 181; puerperal fever, 23 (plus 13 babies); encephalitis lethargica, 126; poliomyelitis, 8; "other diseases," 20. At St. Margaret's Hospital there were 16 babies (plus 8 mothers) with ophthalmia neonatorum.

Of the notifications of enteric fever, 30 were received from the County of London—namely, Hackney, Islington, Lambeth, Paddington, St. Marylebone, Wandsworth, and Westminster each 1, Stepney 2, and Lewisham 21.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 7 (3) from enteric fever, 14 (0) from measles, 8 (2) from scarlet fever, 13 (1) from whooping-cough, 31 (6) from diphtheria, 136 (35) from diarrhœa and enteritis under two years, and 40 (7) from influenza. The figures in parentheses are those for London itself.

Deaths from diarrhœa are now definitely on the decline, the highest figures being reported from Liverpool 11, Birmingham 9, and Leeds 5, while Glasgow and Dublin report 8 each. REASSEMBLY OF PARLIAMENT.

Both Houses of Parliament reassembled for the autumn session on Tuesday, Oct. 29th. The Government have in hand a considerable programme of legislation which they intend to pass before the Prorogation next July. Among the more important Bills are two dealing with Slum Clearance and Reform of the Factory Laws. These measures are likely to be introduced before Christmas, but it will depend upon the progress made with other Bills whether they proceed any further before the reassembling of Parliament early in the New Year.

The Government's Programme.

Mr. Snowden, in announcing the Government's programme of business, said that it was proposed to proceed with the Unemployment Insurance Bill before the Christmas adjournment. It was hoped to make progress with other measures foreshadowed in the King's Speech, including the Factories Bill, to regulate hours of industrial employment. The financial resolution in connexion with the Highlands and Islands Medical Services (Additional Grants) Bill would be placed on the Order Paper on the following day, and a White Paper would also be available.

Notices of Motion.

In the ballot for notices of motion Lieut.-Colonel Fremantle gave notice that to-morrow week (Nov. 6th) he would call attention to ribbon development and move a resolution. Mr. T. Henderson also gave notice of a motion on the nationalisation of water-supply.

HOUSE OF COMMONS.

TUESDAY, OCT. 29TH.

Voluntary Hospitals and Motor Accidents.

Sir William Davison asked the Minister of Transport whether, in view of the serious cost and difficulties thrown on voluntary hospitals throughout the country in the receiving and treating of persons suffering from motor accidents, and also in view of the fact that in very many cases no payment is made to the hospital in question by such persons for their treatment in the hospital, His Majesty's Government would consider the propriety of raising a central fund by means of a small deduction from driving licences, or otherwise, with a view to adequate payments being made to voluntary hospitals who are unable to obtain payment for services rendered in the case of motor accidents.—Mr. Herbert Morrison replied: I do not feel justified in recommending the legislation which would be required to impose a compulsory levy on the drivers of all motor vehicles for this purpose.

Sir William Davison asked if the Minister of Transport did not recognise the serious position that many hospitals were in by reason of their often keeping a special ward, particularly in the country, to deal with motor accidents which interfered with the normal work of the hospitals, and was a great expense to them, when they were already finding it difficult to pay their way. He also asked if the Minister could not introduce some clause at any rate in the legislation which he had promised with regard to third-party insurance, which would deal with this matter.—Mr. Morrison replied that they all recognised the financial difficulties of voluntary hospitals, but he was unable to agree that that was a question which exclusively related to the services required from the hospitals by motorists.

Mr. Thurtle asked if one of the remedies in this matter would not be for motorists to take more care.

Mr. Albery asked the Minister to consider the propriety of approaching the Automobile Association and the Royal Automobile Club with the suggestion that they should try to devise some means of collecting these sums for the hospitals.—Mr. Morrison replied that there was no reason to believe that motorists as a class were less generous in their contributions towards the hospitals than any other section of the community, and it would be difficult to single them out from other users of the hospitals.

Mr. Louis Smith asked the Home Secretary if he would obtain information from the police of the country of the number of accidents treated in local hospitals and resulting from the use of motors during the months from April to the middle of October, with the object of ascertaining the burden now placed on those institutions.—Mr. Clynes replied: I have consulted my right hon. friend the Minister of Health, and am advised that the collection of the figures

Hospital Coöperation at Newcastle.—An advisory committee representative of the voluntary hospitals of Newcastle-on-Tyne has been formed to coöperate *with the municipality in hospital matters, especially* for the prevention of overlapping and for making the best use of the available beds. It is pointed out that, while Newcastle Royal Infirmary has a waiting-list of 2000, there are other voluntary hospitals, fully staffed, not many miles away, with many unoccupied beds.

School Hygiene in Glasgow.—Mr. John Clark, LL.D., who has just retired from the position of Director of Education in Glasgow, was entertained last week to a complimentary luncheon by his many friends in Glasgow, medical and otherwise, in recognition of his enthusiasm in promoting the teaching of hygiene at the training colleges. Both the system of medical examination and the treatment of school-children owe a great deal to his intelligent sympathy and encouragement. He had personal experience of American methods and admittedly education in Glasgow will miss his driving force.

Treloar Cripples' Hospital.—Lord Ampthill, Pro-Grand Master of the United Grand Lodge of England, last week, with masonic ceremony, laid the foundation-stone of the new wards of the Lord Mayor Treloar Cripples' Hospital and College at Alton, Hants. The new buildings will replace the present worn-out wooden huts; they will accommodate 355 crippled children besides 50 crippled boys who are being trained in the college, and will cost £100,000. Last week, also, the coming-of-age dinner of the hospital took place at the Mansion House, under the presidency of the Lord Mayor. It was then stated that since 1908 the hospital had dealt with 6000 children, 95 per cent of them successfully.

Grangethorpe Hospital Closed.—Grangethorpe Hospital, Manchester, one of the best-known war hospitals in the country, *has after 11 years finally closed its doors*, the last patients being transferred elsewhere. During this time 16,000 men have received treatment in the hospital and 7000 operations have been performed. Before the war it was a private residence, and in 1918 it was bought for £11,000 by the trustees of the East Lancashire Homes for Disabled Sailors and Soldiers. For some years the work has been carried on under the authority of the Ministry of Pensions. The building has been presented to the Manchester Royal Infirmary, but it has not yet been decided how the hospital will be utilised. A suggestion has been made that it should be converted into a hospital for middle-class patients who cannot afford nursing-home fees yet wish to pay for treatment.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

Thursday, Nov. 7th.—4.30 p.m. *The following papers will be read*:—W. A. Lamborn: The Remarkable Adaptation by which a Dipterous Pupa (Tabanidæ) is preserved from the Danger of Fissures in Drying Mud (communicated by E. B. Poulton); H. E. Roaf: The Absorption of Light by the Coloured Globules in the Retina of the Domestic Hen (communicated by Sir Charles Sherrington); R. G. Tomkins: Studies of the Growth of Moulds. I. (communicated by Sir William Hardy); R. H. Stoughton: The Morphology and Cytology of Bacterium Malvacearum E.F.S. (communicated by Sir John Russell); E. C. Smith: On the Coagulation of Muscle Plasma (communicated by Sir William Hardy). *The following papers will be read in Title only.*—Sunder Lal Hora: Ecology, Bionomics and Evolution of the Torrential Fauna (communicated by J. H. Ashworth); N. J. Berrill: Studies in Tunicate Development. Part I. (communicated by D. M. S. Watson); J. C. Kernot, J. Knaggs and Madge Kaye: The Swelling of Fish Skins in Solutions of Inorganic and Organic Acids (communicated by Sir William Hardy); A. V. Hill: Anaerobic Survival in Muscle; A. V. Hill and P. Kupalov: Anaerobic and Aerobic Activity in Isolated Muscle; Sybil Cooper and D. Denny-Brown: The Interaction between two Trains of Impulses converging on the Same Motoneurone (communicated by Sir Charles Sherrington); C. H. Best and Ruth Partridge: Observations on Olympic Athletes (communicated by A. V. Hill); H. S. Holden: On the Structure and Affinities of Ankyropteris Corrugata (communicated by D. H. Scott); W. R. I. Mukerji, and Sylvia Wigoder: The Effect of X-Radiation on the Spermatogenesis of Abraxas Grossulariata (communicated by J. P. Hill).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Nov. 5th.—8.30 p.m., Orthopædics. Presidential Address: Mr. D. McCrae Aitken: Respiratory Rhythm in Physiological Relation to Movement and Posture, with Suggested Applications to Treatment. (Illustrated by cinematograph.) 8 p.m., Pathology. Laboratory Meeting at St. Mary's Hospital (Inoculation Department), W. Communications:—L. Colebrook: Sterilisation of the Hands. R. M. Fry and E. H. Davey: The Vernes Test for Tubercle. J. Freeman: Rush Inoculation. R. Hare: Variations in Streptococcal Cultures. I. Maclean: A Bacillus Found in Dental Granulomata. G. Roche Lynch: An Electrolytic Marsh Apparatus for the Estimation of Minute Amounts of Arsenic, Using a Mercury Cathode. Demonstrations:—Sir Almroth Wright: Intertraction. A. Fleming and S. Craddock: The Use of Penicillin in the Isolation of Some Bacteria. G. E. Harre: Human Tar Cancer. D. M. Pryce: The Halo Method of Mensuration. W. D. Newcomb and J. W. Orr: Recent Pathological Specimens. F. T. Ridley: Ossification in the Choroid.

Wednesday.—5 p.m., History of Medicine. Papers: Mr. W. J. Bishop: English Physicians in Russia in the Sixteenth and the Seventeenth Centuries. Dr. J. F. Fulton: Edward Selleck Hare (1812–38) and the Syndrome of Paralysis of the Cervical Sympathetic. 8.30 p.m., Surgery. Discussion on Surgery of the *Spinal Cord. Opener: Mr. Hugh Cairns. Speakers:* Mr. Donald Armour, Mr. Geoffrey Jefferson, Sir Percy Sargent, and others.

Thursday.—5.30 p.m., Tropical Diseases. Prof. A. C. Ukil: Epidemiology and Pathology of Tuberculosis in India (illustrated by lantern slides). Dr. G. Giglioli (provisionally): Paratyphosus C Infections in British Guiana—Sterile Abscess in Treatment (demonstration of specimens—lantern slides). Dr. W. Broughton-Alcock: Section Showing Structures Morphologically Resembling Spirochætes of a Species Common to the Mouth, Lying Deep Within the Mucous Membrane (for opinion). N.B.—Change in hour of Meeting.

Friday.—5.30 p.m., Clinical. (Cases at 5 p.m.) Cases: Dr. C. Worster-Drought: Von Recklinghausen's Disease with Large Cervical Tumour. Dr. H. V. Morlock: Albinism with Enlarged Spleen; Congenital Syphilis with Anæmia. Mr. Cecil P. G. Wakeley: Osteomyelitis Treated by Bone Graft; Cirrhosis of the Liver After Talma-Morrison Operation. Dr. Gerald Slot: Congenital Heart. Mr. R. Rutherford: Late Rickets with Fractures. Dr. Terence East: Hæmophilia. Dr. L. S. T. Burrell: Von Recklinghausen's Disease. Dr. A. J. Scott Pinchin: Case of Coronary Thrombosis with Ventricular Aneurysm; Case for Diagnosis 8.30 p.m. Ophthalmology. (Cases at 8 p.m.). Papers: Dr. Cammidge: Retinitis in Diabetes. Mr. Tudor Thomas and Mr. M. S. Mayou: Sarcoma of the Iris. Mr. M. S. Mayou: Sarcoma of the Iris. Cases and Demonstrations: Miss Hamilton McIlroy: Case of Hereditary Ptosis with Epicanthus. Mr. Tudor Thomas: A Steriliser for Ballantyne's Drop Bottles: A Pair of Prismatic Spectacles. Other cases will be shown.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

Tuesday, Nov. 5th.—5 p.m., Dr. J. A. Arkwright: The Virulence of Micro-organism in Infective Disease (*Bradshaw Lecture*).

Thursday.—5 p.m., Dr. G. F. Still: The History of Pædiatrics in the Seventeenth and Eighteenth Centuries (First Fitzpatrick Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

Monday, Nov. 4th.—5 p.m., Mr. C. P. Wakeley: Specimens of Cysts.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, Nov. 4th, to Saturday, Nov. 9th.—Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., 5 p.m., Lecture by Mr. W. B. Gabriel: Common Rectal Complaints. No fee.—Tues., 8.30 p.m., Dr. J. W. McNee: Structure and Functions of the Spleen in Relation to Its Diseases. Fri., 8.30 p.m., Dr. O. L. V. de Wesselow: Nephritis and Œdema. Two lectures especially suitable for M.R.C.P. Candidates.—Royal Waterloo Hospital, Waterloo-road, S.E. Wed., 10 a.m., Dr. Cecil Bull: *Demonstration of Gastric Diagnosis.* No fee.—Prince of Wales's General Hospital, Tottenham, N. Wed., 2 p.m., Mr. W. Ibbotson: Demonstration of Throat Operations. No fee.—Central London Ophthalmic Hospital, Judd-street, W.C. Special Post-graduate course in Ophthalmology. Every afternoon for four weeks, demonstrations and lectures.—Royal Waterloo Hospital, Waterloo-road, S.E. Special post-graduate course in Medicine, Surgery, and Gynæcology. Every afternoon and some mornings for three weeks.—LONDON LOCK HOSPITAL, Dean-street, W. Post-graduate course in Venereal Disease. Daily every afternoon and evening. Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Nov. 4th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. Dr. Scott Pinchin: Medical Out-patients.

THURSDAY.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

SATURDAY.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.

Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits, Anæsthetic Courses.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham.

WEDNESDAY, Nov. 6th.—4 P.M., Mr. V. Zachary Cope: Radium Therapy.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 4th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, Nov. 4th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Mr. Leslie Paton: Affections of the Optic Nerves.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Purdon Martin: Tumours of the Cerebral Hemispheres.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Ocular Palsies.

FRIDAY.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Symonds: Infectious Diseases of Nervous System.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road.

FRIDAY, Nov. 8th.—4 P.M., Mr. A. Lowndes Yates: Diagnosis and Treatment of the Common Forms of Deafness.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.

TUESDAY, Nov. 5th.—3.15 P.M., Mr. L. E. Barrington-Ward: Visceroptosis.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, Nov. 6th.—4.30 P.M., Mr. Kenneth Walker: The Enlarged Prostate.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.

WEDNESDAY, Nov. 6th.—4.15 P.M., Clinical Meeting and Demonstration of Cases in the Wards. Open to all practitioners.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

WEDNESDAY, Nov. 6th.—2.30 P.M., at B.M.A. House, Tavistock-square, W.C. Quarterly Meeting. Dr. T. Saxty Good: Some Experiments with Suggestion and Association Tests in the Feebleminded. Dr. Geoffrey Shera: Bacillus Acidophilus Deficiency in Mental Patients.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Nov. 5th.—5 P.M., Dr. H. MacCormac: Diseases Due to Animal Parasites.

THURSDAY.—5 P.M., Dr. W. J. O'Donovan: Occupational Dermatitis.

INSTITUTE OF HYGIENE, 28, Portland-place, W.

WEDNESDAY, Nov. 6th.—3.30 P.M., Dr. J. B. Alexander: Modern Diet: Its Effect on the Digestion.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Nov. 6th.—4 P.M., Mr. Stanford Cade: The Possibilities and Limitation of Radium Treatment.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

MONDAY, Nov. 4th.—5 P.M., Prof. Leonard Hill: Atmospheric Pollution.

KING'S COLLEGE FOR HOUSEHOLD AND SOCIAL SCIENCE, Campden Hill-road, W.

FRIDAY, Nov. 8th.—5 P.M., Prof. V. H. Mottram: Human Nutrition. (Fourth of six lectures.)

KING'S COLLEGE, Strand, W.C.

TUESDAY, Nov. 5th.—5 P.M., Mr. J. W. Pickering, D.Sc.: Blood Plasma and Platelets. (Last lecture.)

THURSDAY.—5 P.M., Mr. J. A. Hewitt, D.Sc.: Metabolism of the Carbohydrates and Fats. (Last lecture.)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL, Denmark Hill, S.E.

THURSDAY, Nov. 7th.—9 P.M., Dr. Edward Mapother: Prognosis in Mental Disorder.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.

FRIDAY, Nov. 8th.—6 P.M., Dr. Eric Pritchard: Preventable Disease.

LONDON HOSPITAL MEDICAL COLLEGE, Mile End, E.

FRIDAY, Nov. 8th.—4.30 P.M., Dr. Arthur F. Hurst: Precursors of Carcinoma of the Stomach. (Schorstein Memorial Lecture.)

UNIVERSITY COLLEGE, Gower-street, W.C.

MONDAY, Nov. 4th.—5 P.M., Dr. R. J. Brocklehurst: Secretion of the Digestive Juices. (Last lecture.)

THURSDAY.—5.30 P.M., Rt. Hon. the Viscount Grey of Fallodon: Natural History, the Pleasure and Purpose of Observation. (Rickman Godlee Public Lecture.)

FRIDAY.—5.30 P.M., Mr. C. S. Elton: The Future of Animal Ecology. (Last lecture.)

ANCOATS HOSPITAL, Mill-street, Manchester.

THURSDAY, Nov. 7th.—4.15 P.M., Prof. J. B. S. Stopford: Spinal Tumours.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Nov. 5th.—4.15 P.M., Dr. A. H. Holmes: Meningitis.

FRIDAY.—4.15 P.M., Dr. H. Herd: Behaviour Disorders of Childhood.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC.

FRIDAY, Nov. 8th.—3.30 P.M., Dr. Naish: Gastro-Intestinal Disorders in Infancy and Childhood.

Appointments.

GOUGH, A., M.B., Ch.M. Leeds, F.R.C.S. Eng., has been appointed Hon. Surgeon, Hospital for Women, Leeds.

McCURRY, A. L., M.D., B.Ch. Belf., D.O.M.S., Assistant Honorary Ophthalmic Surgeon to the Leicester Royal Infirmary.

MACINTOSH, J. M., Ch.B., M.D. Glasg., Assistant Medical Officer of Health, Northamptonshire.

Certifying Surgeons under the Factory and Workshop Acts: VAISEY, G. N., L.R.C.P. Lond., M.R.C.S. (Freshford, Somerset), and CONFORD, G. J., M.D. Oxf., B.Ch. Lond. (Felixstowe).

Vacancies.

For further information refer to the advertisement columns.

Bedford County Hospital.—H.S. Also Asst. H.S. At rate of £175 and £130 respectively.

Birmingham City.—Asst. M.O. £750.

Birmingham, Highbury Hospital.—Res. M.O. £350–£400.

Birmingham, Queen's Hospital.—Res. Anæsthetist. £70–£100. Also Jun. R.S.O. £100.

Blackburn and East Lancashire Royal Infirmary.—Fourth H.S. £130.

Blackheath and Charlton Hospital.—Vacancies on Hon. Med. Staff.

Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200. Also Clin. Asst. to Ear, Nose and Throat Dept. £100.

Bolton, Townleys Hospital, Farnworth.—Second Asst. M.O. £225.

Bootle Borough Hospital.—Hon. Surgeon. Also Jun. H.S. At rate of £125.

Bradford Royal Eye and Ear Hospital.—Jun. H.S. £150.

Brighton, Royal Sussex County Hospital.—Sen. Asst. Path. £350.

Brighton, New Sussex Hospital for Women and Children, Windlesham-road.—Radiologist. £100. Also H.P. and H.S. Each at rate of £50.

Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Asst. S.

Chester Royal Infirmary.—H.S. £120.

Colchester, Essex County Hospital.—Asst. H.S. and Registrar. £120.

Coventry and Warwickshire Hospital.—Res. H.P. £160.

Derby County Borough.—M.O.H. £1100.

Dewsbury County Borough.—M.O.H. and School M.O. £900.

Douglas, Isle of Man, Noble's Hospital.—Res. H.S. £175.

Durham County Council.—Asst. Welfare M.O. £600.

East Ham County Borough.—Deputy M.O.H., &c. £700.

Elizabeth Garrett Anderson Hospital, Euston-road.—H.P. Obst. Asst. Three H.S.'s. Each at rate of £50. Also Clin. Assts.

Gloucester, Gloucestershire Royal Infirmary.—Second H.S. At rate of £100.

Gravesend and North Kent Hospital.—Jun. H.S. At rate of £80.

Great Yarmouth General Hospital.—Jun. H.S. £125.

Hampstead General and North West London Hospital, Haverstock Hill, N.W.—Cas. M.O. and Cas. Surg. O. Each at rate of £100.

Hertford County Hospital.—H.P. At rate of £150.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. M.O. At rate of £250.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Res. H.P. At rate of £100.

Hove, Lady Chichester Hospital.—H.P. At rate of £100.
Isleworth, West Middlesex Hospital.—Asst. to Med. Supt. £250.
Inverness, Northern Infirmary.—Hon. Radiologist.
Italian Hospital, Queen-square, W.C.—Res. M.O. At rate of £150.
Jersey General Hospital, &c.—Res. M.O. £200.
L.C.C. Mental Hospital Service.—Eighth Asst. M.O. £300.
Leamington Spa, Warneford General Hospital.—Res. H.S. £165.
Leeds General Infirmary.—M.O. in charge of Radium Dept. £600.
Leeds Hospital for Women.—Hon. Asst. S.
Leicester Royal Infirmary.—Third Res. Anæsthetist. At rate of £250.
London County Council.—Res. Deputy Med. Supt. at The Manor, Epsom. £500.
London Jewish Hospital, Stepney Green, E.—Hon. Asst. Radiologist.
Manchester City.—Asst. Tuber. O. £650.
Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Res. M.O. £200.
Manchester, Salford Royal Hospital.—H.P. £125.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
North Middlesex Hospital, Silver-street, Edmonton, N.—Res. M.O. £200.
Nottingham General Hospital.—Second Cas. O. At rate of £150.
Prince of Wales's General Hospital, Tottenham, N.—Hon. Med. Reg.
Public Dispensary, 12, Drury-lane, W.C.—Res. M.O. £150.
Queen's Hospital for Children, Hackney-road, E.—Cas. O. £100. Surgeon to Ear, Nose and Throat Dept. Also H.S. At rate of £100.
Radium Institute, Riding House-street, W.—Assistant to Medical Department. £600.
Rochester, St. Bartholomew's Hospital.—Res. Surg. O. At rate of £225.
Royal Northern Hospital, Holloway, N.—Med. Reg. £100. Also H.S. At rate of £70.
Royal Society, Burlington House, W.—Foulerton Research Student. £700.
St. John's Hospital, Lewisham, S.E.—Physician to Children's Dept.
St. Mark's Hospital for Cancer, &c., City-road, E.C.—Clin. Assts.
Sheffield, Children's Hospital.—H.P. Also Third Res. M.O. Each £100.
Sheffield Royal Hospital.—Res. Anæsthetist. £80.
Sheffield Royal Infirmary.—Clin. Asst. to Ophth. Dept. Also Clin. Asst. to Med. Depts. Each £250.
Sheffield University, Faculty of Medicine.—Lecturer in Pathology. Also Demonstrator in Pathology. Each £500.
Smethwick County Borough.—Part-time M.O. for Infant Welfare. 1½ gns. per session.
Southampton County Borough Isolation Hospital.—Res. M.O. £360.
Southern Rhodesia Government.—Director of Public Health and Medical Services. £1750.
Walsall General Hospital.—Sen. H.S. Also H.S. At rate of £200 and £150 respectively.
Warrington Infirmary and Dispensary.—Jun. H.S. £175.
West London Hospital, Hammersmith, W.—Asst. Surgeon Dentist.
Willesden General Hospital, N.W.—Res. H.S. At rate of £100.
Windermere, Ethel Hedley Hospital for Crippled Children.—Res. H.S. At rate of £150.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Selby (Yorks).

Births, Marriages, and Deaths.

BIRTHS.

Brown.—On Oct. 25th, at The Vine, Sevenoaks, the wife of W. G. Scott Brown, F.R.C.S., of a son.

Davey.—On Oct. 25th, at "Rockleigh," Gloucester, the wife of Dr. E. N. Davey, of a daughter.

Mackie.—On Oct. 20th, at Louth, the wife of Col. F. P. Mackie, I.M.S., of a son.

MARRIAGES.

Hilton-Sergeant—Walker.—On Oct. 16th, at Dalton Church, *Frederick Cavendish Hilton-Sergeant, Captain R.A.M.C.*, to Kathleen Margaret Howard, second daughter of Mr. and Mrs. Howard Walker, Dalton Grange, near Wigan.

Sexton—Allen.—On Oct. 26th, at Ipsley, Frederic Braemar Worth Sexton, L.D.S. R.C.S. Eng., of Plymouth, to Joan Florence, only daughter of Mr. and Mrs. Allen, of Beoley.

DEATHS.

Braye.—On Oct. 10th, at Hastings, Reginald James Braye, M.R.C.S., L.R.C.P. Lond., late of Leicester.

Cooke.—On Oct. 23rd, at Sawston Vicarage, Cambridge, Thomas Burnard Alfred Cooke, M.R.C.S., L.R.C.P.

Dickson.—On Oct. 22nd, suddenly at "Hartree," Shanklin, Isle of Wight, Frank Lindsay Dickson, M.B., Ch.B., aged 56.

Kendrew.—On Oct. 23rd, in a nursing home, London, Alexander John Kendrew, M.C., M.B., White House, Mile End, Colchester.

Rowlands.—On Oct. 25th, at the Gables, Bromsgrove, Worcestershire, William Herbert Rowlands, M.R.C.S., L.R.C.P.

Russell.—On Oct. 13th, at Holyhead, William Fox Russell, M.B., aged 65 years.

Smith.—On Oct. 22nd, at Trevenn, St. Austell, Cornwall, Ernest George Smith, M.R.C.S., L.R.C.P. Lond., late of Ford Park-road, Plymouth.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

ARTIFICIAL CREAM ACT PROSECUTION.

In our issue of August 24th (p. 418) we noted the first prosecution under the Artificial Cream Act, 1929. Our summary of the evidence attributed to the defendant company (the Ferns Pure Milk and Cream Co.) the statement that a Government analysis showed that its cream was reconstituted cream with a low fat content. The company supplies us with independent analyses, showing the fat content of the preparation, and points out that its manager, in the evidence referred to, was referring not to the company's cream, but to that sold by certain dairy companies. We gladly publish the correction, and regret the occurrence of the error.

SEWAGE DISPOSAL.

In his Chadwick lectures, delivered on Oct. 17th and 19th, Mr. A. J. Martin dealt broadly with the problems of sewage disposal. Concentration of population gives rise to many difficulties which do not occur in scattered communities, not the least of these being the disposal of excreta. To illustrate the rather reckless way in which our not very remote ancestors dealt with sewage, Mr. Martin quoted Sir Robert Rawlinson's question, "Is it better to kill fish, or to kill men?" Methods of land disposal, appropriate enough when land was cheaper, had had their day, and chemical precipitation was a thing of the past. Sewage was by no means the dead and depressing thing that it looked, as it contained in itself the agents of its own purification. It was, however, necessary to give these organisms a chance of doing their work, to provide laboratories, and, in some cases, reagents for them. The modern bacteriological treatment *of sewage had its beginnings in the coke-bed set up by the* London County Council on the advice of Mr. Dibdin, and the septic tank first erected by Cameron at Exeter. The problem of sewage purification is too often complicated by the presence in sewage of large quantities of industrial wastes, among which the products of two new and growing industries, beet sugar and artificial silk, present special difficulties, which are not yet fully overcome. Many streams are badly polluted with these by-products, which are often discharged without appreciable treatment.

In his second lecture, which was largely historical, Mr. Martin stated that the purification of foul matter is most effectually achieved by oxidation; but whereas solid refuse is quickly burnt at a high temperature, the waste matters in sewage, *diluted as they are with many thousand times* their weight of water, can only be oxidised by the slow processes of moist combustion at ordinary temperature. In a small country like England, with no great lakes or rivers where this process can go on in very dilute solutions without artificial aid, special works and artificial means of introducing the necessary oxygen must be adopted. Even a vast country like the United States of America has sewage problems which are still outstanding. The ease with which a large proportion of the suspended solids of sewage can be removed by sedimentation points, said Mr. Martin, to this as an obvious preliminary measure before bacterial (or rather biological) treatment is used. Fifteen years ago it appeared that sedimentation tanks followed by treatment on trickling filters would *be the standard form of disposal*, but at that time Dr. Fowler threw a bombshell into the camp in the form of the activated sludge process. In this the usual course is reversed, and instead of the sewage passing over the active material, this latter, in the form of a flocculent humus-like suspension, is passed through the sewage. More was expected of the activated sludge process than has perhaps been realised, and where full purification is required it is usually advisable to provide filters. Nevertheless, by interposing activated sludge treatment, a city like Birmingham has been able to save the cost of laying down an additional acre filter-bed each year. London sewers laid 60 years ago are still doing good work, and for half a century the Thames has received the whole of the liquid sewage; *but the volume discharged is now out-*growing the capacity of the river to deal with it, and the London County Council are about to lay down supplementary works of a novel character. What to do with the sludge produced by sedimentation is not easy to decide. In some places it is dealt with by digestion, and latterly successful attempts have been made to utilise the large volumes of combustible gas evolved. At Essen, Dr. Imhoff sells the gas so produced to the municipality, and Mr. Martin remarked, for the benefit of Sir G. W. Humphreys, who was in the chair, that the northern outfall for London sewage was adjacent to the Becton gas-works. He closed with a note of warning about the waste of nitrogen involved in most of the present means of sewage disposal.

MATERNAL MORTALITY AND PUBLIC OPINION.

Mr. Arthur Greenwood, speaking at a Conference arranged by the Maternal Mortality Committee, and held at the Central Hall, Westminster, on Oct. 22nd, mentioned two of the good things which, as Minister of Health, he had inherited from his predecessor. These were the committee appointed to make a scientific investigation into the problem of maternal mortality, still at work, and the departmental committee on the training and employment of midwives, which had already reported. He also drew attention to the memorandum of the British Medical Association setting out a scheme for a national maternity service, and to the findings of the Royal Commission on National Health Insurance. Some of the recommendations of the committee on midwives could be set in motion under existing laws, but the major proposals of the report would require legislation. Many local authorities were not at present using a fraction of their powers in the matter of maternity service, and he was prepared to encourage, stimulate, and press them in every way to make effective the powers they already possessed. This, however, was largely a matter of public opinion; if 20 millions of people urged certain things with strength and determination, those things would be done. Mr. Greenwood said that he was no opponent of fresh legislation and, though it was difficult for him to give any pledge, he hoped it might be possible, at no distant date, to deal with the problem in a broad and comprehensive fashion, fitting it into the general provision being made to maintain and improve the standard of public health, and also into the provision being made through a system of social insurance.

This statement made it easy for Mrs. Hubback to introduce a resolution welcoming the recommendations of the departmental committee to make available for all mothers skilled attention and nursing before, during, and after childbirth, urging the Minister of Health to put the recommendations into force as soon as possible, and pledging the Conference to give him active support. It was evident, she said, that the Minister was going to merit his title, and all the public had to do was to back him up. Dr. H. B. Brackenbury, chairman of the Council of the British Medical Association, went further, saying that medical men had already shown themselves entirely in sympathy with the movement, of which they had, indeed, been pioneers. Public opinion was already ripe for action, and officials need have no hesitation in going ahead at once with a scheme such as that outlined by the British Medical Association. If Mr. Greenwood had introduced a measure on this subject as his first Bill, after taking office, there would have been no opposition. At the end of the meeting Mrs. Hubback's resolution was put to the Conference by Lady Cynthia Colville, the chairman, and was passed unanimously.

THE PATHOLOGIST ABROAD.

Dr. Austin Freeman[1] in this substantial volume brings together 37 examples of the uncanny detective ability of his now famous creation, Dr. Thorndyke. Seeing that Dr. Freeman has done medical service as house physician to the Middlesex Hospital, as a colonial surgeon, and as a surveyor and naturalist on political expeditions, he is able to conduct his readers from personal knowledge along very varied and curious pathological paths; and as all this assortment of wisdom resides, filed and indexed, in Thorndyke's brain, it becomes *natural* that he should regularly arrest the course of crime by the discovery of clues, the bare existence of which could never have been anticipated by the actor—"natural" is the right word, for Dr. Freeman, with great skill and accuracy, contrives always to account satisfactorily for episodes that are incredible. That is the main reason for his well-deserved popularity as a writer of detective fiction, and it is because he is so well documented that he has been able to create interest in what he terms the inverted story. Such a story opens with a narration of what has happened, so that the pleasure of the reader is not due to any excitement as to who did the crime or as to how it was done; these things we are told, but the fun depends on the intellectual exercise spent upon estimating the methods employed in detection. Obviously such a machinery for telling a story could only be employed by a writer who felt perfectly sure that each step in tracking down was taken upon sure ground.

Many will have seen some or all of these stories before, but no one without Thorndyke's powers of memory can have kept such an assortment of episodes in their head. We commend the book, as a diversion, to all our readers.

MUSSEL POISONING.

A MYSTERIOUS poisoning has been found to result from the eating of mussels on the western American coast, particularly in districts north of San Francisco. Investigators have satisfied themselves that the poison is not formed by bacteria and that it is heat stabile in acid solutions. No means have been discovered yet of distinguishing wholesome from poisonous mussels. It is thought that the poison results from some metabolic disorder of this shellfish influenced by its food, and perhaps by the spawning conditions. It may be necessary to determine a closed season for mussels, in this region at least. In the meantime warnings have been issued by the California State Department of Health as to the danger of using mussels for food. Those who, soon after eating mussels, experience tingling or numbness around the lips and a prickly sensation in the finger tips or toes, are advised to call a physician at once.

THE CALL OF THE HIGH-VELD.

UNDER this title Dr. L. E. Hertslet has written a useful little pamphlet for "South African Railways and Harbours," which can be obtained from any office of Messrs. Cook and Son, and from the offices of the Union of South Africa, Trafalgar-square, W.C. The author gives a brief summary of the climatic and physical features of the country together with health statistics, an account of the facilities for recreation, and many notes which will be helpful to those who contemplate visiting "a land where the summer nights are cool and the winter days filled with sunlight, where it is not too wet and seldom too dry, where the barometer 'plays no tricks,' where the health-rates are good, where the altitude is not troublesome, and the atmosphere delightfully clear."

MECHANICAL MAN.

Mr. H. Stafford Hatfield, the author of Automaton, or the Future of the Mechanical Man,[1] gives instances of automatic processes either already invented or capable of being brought into existence and draws gloomy conclusions from their contemplation. He suggests that as these devices come into being life will become dreary and monotonous, ignoring the fact that the more complicated and skilled machinery and processes become the more skilled are the men needed to tend them. He argues from analogy that modern civilisation, largely based on such automata, must fall away just as it has risen. Analogy, however, here seems false, since the human race has been steadily, but with increasing velocity, developing its command over its environment for some half million years. We can afford to disregard the possible decline of a wave of progress which is still rising after so prolonged a period.

SNAKE-BITES.

A LITTLE book,[2] by Mr. F. W. Fitzsimmons, Director of the Port Elizabeth Museum, Cape Town, supplies in accessible form an account of the right ways of treating snakebite. The mortality, permanent physical and mental disability arising from snake-venom poisoning in South Africa is known to be comparatively heavy, though no statistics are kept of the number of cases of snake-bite. Both the expert and the tyro in snake-lore will find matter to interest them in this book, and the section dealing with the prevention of snake-bite is of especial interest. Medical officers and adventurous members of the lay public will also acquire much accurate information upon snakes and their unwelcome habits.

A REMARKABLE HOSPITAL BAZAAR.—A five days' bazaar in aid of the new Infirmary at Dewsbury has produced £22,153.

HOSPITALS AND MOTOR ACCIDENTS.—Members of Parliament who are interested in hospital questions and regional secretaries of the Association are being circularised by the Council of the British Hospitals Association with reference to the expense caused to hospitals by the treatment of sufferers from motor accidents. The Council say they have agreed to press for some recognition of the claims of the voluntary hospitals in this regard. Earl Russell, who is about to introduce a Bill dealing with road traffic, has informed Sir Arthur Stanley that the advisability of including in the measure some form of compulsory insurance for motorists is under consideration. Last year the treatment of patients injured in motor accidents cost three Glasgow hospitals over £10,000.

Bradshaw Lecture

ON THE

VIRULENCE OF THE MICRO-ORGANISM IN INFECTIVE DISEASE.

Delivered before the Royal College of Physicians of London on Nov. 5th, 1929,

By J. A. ARKWRIGHT, M.D. Camb., F.R.S.,

FELLOW AND COUNCILLOR OF THE COLLEGE; ASSISTANT BACTERIOLOGIST AT THE LISTER INSTITUTE.

The problem of virulence has been and still is among the most arresting and fundamental subjects in the study of infective disease. Like that of the Origin of Sin, which has proved a difficult knot to loose even by the combined efforts of theologians and psychologists, and the Mystery of Pain, which was dealt with in so illuminating a manner by James Hinton, a distinguished Member of the sister College, the nature of virulence in infective disease has been the subject of much speculative discourse. In the case of virulence this phase of speculation has now given way to one of fruitful experimental investigation.

Since the doctrine of *contagia viva* has been firmly established the epithet "virulent" has been transferred from the disease to the living causal parasite by a lively metaphor which envisages a venomous germ attacking the innocent animal body.

Twenty years ago it was pointed out to me by the Director of the Lister Institute that the decline in cultures of bacteria from a state of high virulence and their occasional return to malignant activity, especially during sojourn in the animal body, was still a most baffling phenomenon, and one which often presented formidable obstacles to experimental workers and frustrated therapeutic investigations; consequently that it was worthy of deliberate study, though the elucidation might be long delayed. At that time the elusiveness of virulence in cultures of *Bacillus pestis* was a constant source of difficulty in preparing and testing plague vaccine and the obstacle has not yet been entirely overcome. The reason of the behaviour of attenuated cultures of *B. anthracis*, such as were used by Pasteur for anthrax vaccination, was and still is an unsolved problem, and the matter has not yet been specially examined by more recent methods. During the last 15 or 20 years, however, a certain amount of light has been thrown on the subject from various sides.

The experimental bacteriologist is apt to seek virulent cultures and to express pleasure when he obtains them. This craving might well be the sport of the uninitiated, since superficially it suggests the practices of a professional poisoner or the infatuated action of desperate combatants in modern warfare, as dreamt of by overwrought and ill-instructed military hygienists. Let us hope, however, that these things are but the food on which nightmares are nourished.

It may be well to recall shortly the reasons for the study of virulence in disease-producing parasites.

(1) In the first place it has been the belief of clinical observers and some epidemiologists that unusual virulence of the *materies morbi* is the reason of the greater severity and higher mortality of one outbreak of infectious disease than of another. It has, however, on the other hand, been suggested that these differences are due rather to changes in the population attacked, induced by temporary causes such as climatic, or dietary changes or by more subtle factors, which bring about a greater or less resistance of the animal subject. These contingencies are very hard to determine or estimate even by the skilful collection and treatment of statistics. In the hope of understanding these occurrences and of guarding against the more severe outbreaks, it is obviously important to know to what extent the living parasitic agent which excites the disease can itself vary, and to find out whether this change can be controlled. Again (2) the experimental pathologist often desires to have at hand a uniformly and sometimes an excessively active causal micro-organism in order to produce at will some disease in animals, for the study of all its features and especially so as to be able to test various remedial or preventive measures. For these purposes it may be necessary to make observations on a series of animals inoculated with uniform doses of the infective agent. (3) Knowledge and control of virulence are particularly important when actual cultures of the pathogenic agent, alive or dead, are used for prophylactic purposes. Moreover, in certain instances one culture or sample of pathogenic material will produce a mild attack which protects against the more severe, as in vaccinia, rabies, fowl-pox, and anthrax. For such purposes cultures or "inocula" of both weak and strong virulence but containing microbes otherwise the same are needed for experiment. Also (4), the use of dead bacteria as prophylactic "vaccines" has introduced the question whether it is needful that the cultures should have had all the properties of pathogenicity when they were alive, or whether virulence and toxicity are mere excrescences which may cause undesirable symptoms, even when the cultures used are dead, but that these qualities are not essential in order to stimulate the apparatus of defence. In the case of the allied procedure for producing antitoxin it is, of course, now well known that certain toxins, such as diphtheria toxin, can be changed into toxoids, or anatoxin, which has no obvious poisonous action but yet can be used to produce antitoxin in the bodies of man and animals. But the desirability of using virulent bacterial cultures for vaccines has been comparatively little studied.

For all these reasons the study and control of virulence are of prime importance.

(5) Allied to changes in virulence, but probably not due to exactly the same factors, are the changes in pathogenic bacteria, protozoa, and viruses which so adapt them to the animal host that they cause disease in one species but not in another. One may adduce many modern instances which appear in the recent work on pasteurellosis or hæmorrhagic septicæmia of animals, vaccinia, distemper, foot-and-mouth disease, herpes, &c. It is obvious, therefore, that variation in virulence is no idle study.

It is, then, of the *variability* of bacteria as regards their virulence and their capacity for harmful action on the bodies of animals that I wish to treat.

The Meaning of Virulence.

Virulence in the general sense is the property by which a pathogenic micro-organism causes death or reaction of the part or parts of the body invaded and so leads to disease. Infective disease may be defined as the resultant or sum of the action of the infecting agent and the reaction of the body.

It has sometimes been objected that it is idle to speak of the virulence of a bacterium, since this quality depends on the interaction of the micro-organism and the animal which it infects and on the conditions which it finds in its host. The reason given for this opinion is in itself very true, but since the great variability of strains or races of pathogenic bacteria is now well recognised it has become clear that differences in the characters of different cultures of the same microbe may be such as to render it highly active or almost inert in respect of disease production, when introduced into the body even of a highly susceptible animal. A more just criticism is that the term virulence, as often used, includes a number of different qualities. The different forms of pathogenic action no doubt often combine to produce the result so that it is difficult to say which is most active in a given case. Since, however, I wish to deal chiefly with a particular part of the subject, I must make an attempt to analyse the property of pathogenicity and show how the different qualities affect in the chair, that the northern outfall for London sewage was adjacent to the Becton gas-works. He closed with a note of warning about the waste of nitrogen involved in most of the present means of sewage disposal.

MATERNAL MORTALITY AND PUBLIC OPINION.

Mr. Arthur Greenwood, speaking at a Conference arranged by the Maternal Mortality Committee, and held at the Central Hall, Westminster, on Oct. 22nd, mentioned two of the good things which, as Minister of Health, he had inherited from his predecessor. These were the committee appointed to make a scientific investigation into the problem of maternal mortality, still at work, and the departmental committee on the training and employment of midwives, which had already reported. He also drew attention to the memorandum of the British Medical Association setting out a scheme for a national maternity service, and to the findings of the Royal Commission on National Health Insurance. Some of the recommendations of the committee on midwives could be set in motion under existing laws, but the major proposals of the report would require legislation. Many local authorities were not at present using a fraction of their powers in the matter of maternity service, and he was prepared to encourage, stimulate, and press them in every way to make effective the powers they already possessed. This, however, was largely a matter of public opinion; if 20 millions of people urged certain things with strength and determination, those things would be done. Mr. Greenwood said that he was no opponent of fresh legislation and; though it was difficult for him to give any pledge, he hoped it might be possible, at no distant date, to deal with the problem in a broad and comprehensive fashion, fitting it into the general provision being made to maintain and improve the standard of public health, and also into the provision being made through a system of social insurance.

This statement made it easy for Mrs. Hubback to introduce a resolution welcoming the recommendations of the departmental committee to make available for all mothers skilled attention and nursing before, during, and after childbirth, urging the Minister of Health to put the recommendations into force as soon as possible, and pledging the Conference to give him active support. It was evident, she said, that the Minister was going to merit his title, and all the public had to do was to back him up. Dr. H. B. Brackenbury, chairman of the Council of the British Medical Association, went further, saying that medical men had already shown themselves entirely in sympathy with the movement, of which they had, indeed, been pioneers. Public opinion was already ripe for action, and officials need have no hesitation in going ahead at once with a scheme such as that outlined by the British Medical Association. If Mr. Greenwood had introduced a measure on this subject as his first Bill, after taking office, there would have been no opposition. At the end of the meeting Mrs. Hubback's resolution was put to the Conference by Lady Cynthia Colville, the chairman, and was passed unanimously.

THE PATHOLOGIST ABROAD.

Dr. Austin Freeman [1] in this substantial volume brings together 37 examples of the uncanny detective ability of his now famous creation, Dr. Thorndyke. Seeing that Dr. Freeman has done medical service as house physician to the Middlesex Hospital, as a colonial surgeon, and as a surveyor and naturalist on political expeditions, he is able to conduct his readers from personal knowledge along very varied and curious pathological paths; and as all this assortment of wisdom resides, filed and indexed, in Thorndyke's brain, it becomes *natural* that he should regularly arrest the course of crime by the discovery of clues, the bare existence of which could never have been anticipated by the actor—"natural" is the right word, for Dr. Freeman, with great skill and accuracy, contrives always to account satisfactorily for episodes that are incredible. That is the main reason for his well-deserved popularity as a writer of detective fiction, and it is because he is so well documented that he has been able to create interest in what he terms the inverted story. Such a story opens with a narration of what has happened, so that the pleasure of the reader is not due to any excitement as to who did the crime or as to how it was done; these things we are told, but the fun depends on the intellectual exercise spent upon estimating the methods employed in detection. Obviously such a machinery for telling a story could only be employed by a writer who felt perfectly sure that each step in tracking down was taken upon sure ground.

Many will have seen some or all of these stories before, but no one without Thorndyke's powers of memory can have kept such an assortment of episodes in their head. We commend the book, as a diversion, to all our readers.

[2] Snakes—and the Treatment of Snake-bite. The Speciality Press of S. Africa, Ltd. 1929. Pp. 70.

A REMARKABLE HOSPITAL BAZAAR.—A five days' bazaar in aid of the new infirmary at Dewsbury has produced £22,153.

HOSPITALS AND MOTOR ACCIDENTS.—Members of Parliament who are interested in hospital questions and regional secretaries of the Association are being circularised by the Council of the British Hospitals Association with reference to the expense caused to hospitals by the treatment of sufferers from motor accidents. The Council say they have agreed to press for some recognition of the claims of the voluntary hospitals in this regard. Earl Russell, who is about to introduce a Bill dealing with road traffic, has informed Sir Arthur Stanley that the advisability of including in the measure some form of compulsory insurance for motorists is under consideration. Last year the treatment of patients injured in motor accidents cost three Glasgow hospitals over £10,000.

The application of chemical researches to bacterial variation will be pointed out later. The two branches of investigation have helped each other, and, as will be seen later, much of the older chemical work was less fruitful than it might have been because bacteria were regarded too much as a whole, without appreciating that they might consist of separate parts of diverse function and composition. In consequence, the variation of these parts when it occurred was taken to mean a change in a single chemical substance, instead of independent variations quantitative and qualitative in the separate parts or "organs" of the bacillus. It is now known that both these kinds of changes occur, but the speculations of former days did not give a correct interpretation of the facts.

(3) *Bacterial Variation.*—The lines along which more strictly defined bacteriology is progressing are those which I chiefly desire to emphasise. They are based on the evidence of variability of bacteria, especially as regards virulence amongst other characters which has received much attention of late years. Finished results must not be expected at present. Suggestive facts and a few experimental hints are all that can be boasted of as yet, but they are of great promise.

There are two main aspects of variation in virulence, and it is necessary to consider them separately. The first is the evidence of their different behaviour in the animal body, and the second is the evidence of variation in the morphology of the bacteria and their colonies and in their chemical composition and properties in vitro.

VARIED BEHAVIOUR OF ORGANISMS IN THE BODY.

Variation in toxigenicity.—In artificial cultures the same strain of a bacillus may vary very much from time to time in the concentration of toxin which it will yield, a fact which is the bugbear of those whose duty it is to obtain a "good" toxin for the production of antitoxin. Non-toxigenic variants of the diphtheria bacillus have been isolated from strains of high repute as toxin makers by several workers, Baerthlein, Maitland, and Crowell, though other good observers have repeatedly failed to do so.

Variation in invasive power.—Virulence in the stricter sense means ability to invade the tissues of the host and multiply there. In many cases the laboratory in-vitro tests of virulence have been made by techniques which show the readiness with which the bacteria will undergo bacteriolysis or be taken up by phagocytes or behave in the complement-fixation reactions when under the influence of specific immune serum containing antibodies. These experiments are really concerned with the question whether the particular serum fits the bacteria—i.e., contains antibodies to the special antigens in the particular cultures used. They do not indicate their capacity for infecting susceptible animals. The most desirable tests of virulence are those which show the effect of the serum and tissues of the normal susceptible animal on the bacterial strain rather than the effect of the serum of an immune animal. In practice it is the susceptible animal which is the measure of virulence and not one which is immune. At present the direct test of pathogenicity and lethal effect of inoculated cultures is the best method of estimating virulence, but this is open to many special difficulties and fallacies, and it is partly on this account that the more easily recognisable characters of cultures in vitro which are correlated with virulence are of special value.

Variations in virulence shown by animal experiment.—The virulence of different cultures of the same strain of the same kind of micro-organism may vary enormously as shown by animal experiment. The pneumococcus and streptococcus are well known instances of this. Griffith obtained two variants of a single strain of pneumococcus with very wide differences in virulence. Dr. G. F. Gaskell in a former Bradshaw lecture described the pathology of pneumonia in rabbits which had been produced by the inoculation of cultures of different virulence. He found the variation in virulence such that the minimum lethal dose for a mouse varied between 1·0 c.cm. and one ten-millionth of 1·0 c.cm. of an 18 hours' broth culture. Eagles examined four different variants of a single strain of streptococcus and found that their lethal doses varied from 10 million to 100 cocci. G. S. Wilson injected mice with virulent and non-virulent cultures of *B. aertrycke* and found that whereas the former killed 2 mice out of 20, the virulent variant killed 18 or 19 out of 20 in one-twentieth of the dose, a difference of 1 to 180. Comparable differences may be found in *B. pestis*, *B. anthracis*, and the filtrable viruses.

Since variation in virulence of cultures is an accepted fact, several questions at once arise. What is its exact nature—i.e., what is the intimate change in the bacteria composing the cultures? How can these changes be encouraged or prevented? What other changes accompany changes in virulence? How are the changes observed to appear?

Pfeiffer in 1903 discussed the known facts and regarded the loss of virulence as of the same kind as atrophy of function from disuse, and its recovery as due to renewed opportunity for action aided by survival of the fittest—i.e., of the most virulent bacteria—in the animal body. A view essentially similar to this is perhaps the most acceptable to-day. At that time, 20 years ago, however, much ingenuity was expended in trying to fit in the facts with complicated views about haptophore and toxophore or ergophore chemical groups in the bacteria. These views dealt with substances too hypothetical to allow of profitable argument or sound conclusions and subsequent verification. Such conceptions still have their value, especially in relation to exotoxins, but seem to have led the protagonists astray. Pfeiffer and Hamburger believed that it was the antibacterial action of the amboceptors in the serum of normal animals which accelerated or brought about the change and that consequently culture in the serum or the bodies of immune animals would be still more effective in promoting virulence. Walker and Shaw attached more importance to the destructive action of the complement or alexin in this capacity. It is probable that neither as such has much influence and certainly the evidence points to the so-called amboceptor having an exactly opposite effect.

KINDS OF VARIATION.

Variation in bacteria as in other living things may concern large or small changes, in single or in groups of characters. Such characters are motility, serological properties, manner of growth in culture, agglutinability by salt, &c., in addition to changes in virulence.

It has been considered an important question from the point of view of the geneticist whether the changes are all due to loss or may also be due to acquirement of a character. It is often hard or impossible to say which is which, for an apparent gain may be due to the loss of some inhibitory factor and vice versa. If the acquiring of the power to ferment a sugar or if the gain of a capsule and of virulence or the adaptation to a new species of host is a true gain, as these changes appear to be, then gains certainly occur as well as losses. It has been argued that the apparent acquisition of a new character is really due to the survival of the few individuals which have had this character all the time, or even to the hypertrophy of a dormant character and not to a really new acquisition. But it is not clear why such latent properties in a culture should be postulated if they cannot be observed. It seems probable that a character first appears in a few individuals, and that then its relative increase is encouraged by selection, and often the same factor in the environment which produces the first variants also favours their selection. This is very strongly indicated when a species of bacterium acquires the property of fermenting a sugar on which it did not act on in the first place. The presence of the sugar conditions the appearance of a few bacteria capable of effecting the fermentation, and these are then encouraged and selected because they have the advantage of a new pabulum which is denied to the others. In the same way, and perhaps for the same reasons, there is a likelihood that adaptation to animal tissues and juices is produced by the presence of these tissues or their chemical constituents which first produce a new quality in the bacteria and then afford an additional nutriment to the new race which increases in consequence.

The bogy of inheritance of acquired characteristics, moreover, need have no terrors for the bacteriologist, since bacteria are not known to have differentiated reproductive organs nor to undergo conjugation or a sexual phase, though such life-histories have been described. Consequently the theoretical readjustment with reversion to type at these stages need not be taken into account. There seems to be no sound theoretical objection to hereditary variation of bacteria being influenced by direct environmental influence followed by environmental selection. Such variations have been described in the kind of variants called "clones" in protozoa which persist for long periods of repeated asexual multiplication but are believed usually to come to an end when conjugation has occurred. Such automatic intensifying action on variation by the environment which both causes variation and then selects the variant seems especially indicated in certain bacterial variations—e.g., (1) the fermentation of a new sugar, (2) adaptation of a species of bacterium to a new host, (3) increase of virulence during passage through a susceptible animal, (4) diminution of virulence during passage through immune serum, (5) the change from a non-virulent uncapsulated pneumococcus into a capsulated virulent variant, which has been described by Griffith as the result of passage through a mouse together with a dead emulsion of capsulated pneumococci.

VARIATIONS WHICH CAN BE DETECTED IN CULTURES.

Variants of very diverse characters can be obtained by selection of colonies on agar culture medium. Almost every known character has been observed to vary in one species of bacterium or another. By persistent selection of colonies growing on agar plates made from old broth cultures or from cultures in special media a persistent or hereditary variant can be obtained corresponding to each of these altered characters. Some of the best marked hereditary variants that can be detected in cultures must be described.

Variants are said to be hereditary when they can be kept pure by subculturing on agar at fairly short intervals without the need for fresh selection of isolated colonies. Four very distinct kinds of variants are now well known in the group of intestinal bacteria which includes *B. coli*, *B. typhosus*, and *B. paratyphosus*. Many other hereditary variants are also recognised, but these four have been shown to have a definite position as regards virulence. The four variants are as follows.

(1) The so-called normal strain recently isolated from the body. This is typically motile and makes a turbid growth in culture bouillon, and on nutrient agar forms round, dome-shaped colonies with smooth shining surface and a regular margin. This is called the smooth motile form or shortly the S.M. form.

(2) Colonies on agar of such a strain can often be found which are similar in appearance but contain only non-motile bacteria; these may be indicated as S.N.M. This variant has been called the O form by Weil and Felix because the growth in the case of *B. proteus* is different from that of the motile form. The latter makes a confluent filmy growth all over the surface of agar and consequently Weil and Felix called it the H form because of the "Hauch" or film characteristic of it. The non-motile form they described as "ohne Hauch" or "O."

(3) The next variant is also motile like the S.M. or normal, but instead of growing in smooth round shiny colonies with even edges the colonies are more or less irregular in outline, rough and uneven or dull on the surface, and of a granular and often opaque texture and a jagged outline. This has been called the Rough or R form to distinguish it from the S. Since it is motile it is also named R.M.

(4) The fourth form or R.N.M. is non-motile, like the second, but is rough like the third.

Mixed and intermediate variants occur, but these four forms can often be obtained pure with some little trouble by repeatedly selecting colonies; they will then often keep constant if transplanted at intervals of a week for very many subcultures, each of which represents hundreds of thousands of divisions or bacterial generations.

Virulence and capsule.—Perhaps the most important variants for my present purpose besides those described above are the capsulated and non-capsulated forms of pneumococcus and of the pneumobacillus of Friedländer whose colonies can be recognised on solid media. These will be again referred to later.

The four forms of variants of *B. typhosus*, &c., depend on two pairs of characters for their differentiation, motility, and absence of motility, "smoothness" and "roughness." The corresponding components are the flagella, which are responsible for motility, and the "smooth" (S) somatic antigen or the "rough" (R) somatic antigen, which constitute smoothness or roughness.

WANT OF CONNEXION BETWEEN VIRULENCE AND MOTILITY: PRESENCE OF FLAGELLA.

As far as the evidence goes at present "motility" has no relation to virulence nor to toxigenicity. That is to say, a motile S and a non-motile S culture are both of approximately the same pathogenicity as far as is known, and the same is true of a rough motile and a rough non-motile, though in this case the pathogenicity is of a very low order.

Motility means the presence of flagella, and the presence of this constituent in emulsions of motile bacteria is shown by the manner of reaction with specific agglutinating serum. The flagellated bacteria agglutinate in large loose fluffy floccules and emulsions of the non-motile variant with agglutinating serum form small, dense granular clumps. It has, in fact, been shown that motile bacteria possess two kinds of agglutinable substances which condition the formation of clumps with specific sera, whilst the non-motile form has only one corresponding to the bodies of the bacteria which is consequently called the somatic substance as opposed to the flagellar substance. When an animal has been infected with or inoculated with motile bacteria two agglutinins appear in its serum which act on the flagella and the bodies respectively, but if a non-motile and completely unflagellated variant or species has been inoculated then the serum contains only agglutinins for the somatic antigen or agglutinable substance.

As has been pointed out above, it is the somatic substance which is most nearly related to virulence and the flagellar has not been shown to make much difference in this respect. It has also been shown that such reactions with serum in vitro as bacteriolysis, bactericidal action, and complement fixation are for the most part, if not quite entirely, concerned with the somatic part of the bacteria and are related to the nature of the somatic antigen, but they have very little indeed to do with the flagellar part. It has also been found in *some* experiments that in order to give an animal protection against a particular motile organism it is unnecessary to use a motile form or variant for the protective inoculation or vaccine. This is in harmony with what has just been said about most of the known in-vitro immunity reactions being all concerned with the somatic part of the bacteria.

The hypothesis that the elaborate flagellar apparatus of such bacteria as the typhoid or paratyphoid bacillus is of no importance as regards pathogenicity is at first sight rather startling, but it is borne out by certain other facts. It has been observed that motility varies with the temperature of incubation in some strains of *B. typhosus*, *B. paratyphosus* A, and other bacteria. For instance, all strains of *B. pseudo-tuberculosis rodentium*, a plague-like bacillus which causes disease in guinea-pigs and rabbits and occasionally in man, are motile when the incubator is kept at 70° to 80° F., but when the cultures are kept at 95° to 98° F. they are no longer motile and often they do not form any flagella. This fact alone suggests that flagella do not play an important part in infection, since the body is never cool enough for them to develop readily in these strains, which may nevertheless be quite pathogenic.

Further, it is not very uncommon to obtain from the blood in typhoid fever only non-motile cultures. It is true that they usually become motile after being subcultured once or twice, but the motile character is evidently suppressed in the blood and tissues of these patients, and this assumption is made the more probable by finding that in some groups of cases the patient's serum when used for a Widal reaction fails to give the typical flocculent clumping of flagellar agglutination even when the emulsion used for the test is well endowed with flagella. This defect in the typical Widal reaction was found in 25 per cent. of the cases of typhoid examined by Felix in Palestine and in 75 per cent. of cases tested by Pijper in Johannesburg. Other workers in South Africa have had a similar experience. So frequently did Pijper find the Widal test fail that he ceased to attach much importance to it. It is now, however, realised, as the result of Felix's work, that the serum of such patients does still agglutinate the bodies of typhoid bacilli in a characteristic manner, though the serum contains no flagellar agglutinins. The somatic clumping is not so obvious and needs some hours incubation of the agglutination tubes before it is apparent. For this reason somatic agglutination has very often been missed and not taken into calculation in agglutination experiments.

RELATION OF THE SOMATIC ANTIGEN TO VIRULENCE.

Since the flagellar part of the bacteria appears to be of such little pathogenic importance it remains to consider the constituents of the bacterial bodies which can be detected and to some extent measured by serum reactions, especially by agglutination, which is probably a fair measure of the somatic antigens.

R. variant. Non-virulent.—In old laboratory cultures of *B. typhosus* and *B. dysenteriæ*, the specific smooth somatic agglutinable substance often becomes altered to that found in the R form so that it loses its specificity. These R bacteria then give less specific reactions and they agglutinate with sera made for the R form of other species of bacteria and have also lost their virulence. This "rough" change is promoted by growth in strong nutrient broth. In much more dilute broth—e.g., diluted with water four or five times—it keeps its S characteristics much longer. The replacement of S by R bacteria in old laboratory cultures in great part, if not altogether, accounts for their loss of virulence.

R variant produced by anti-"S" serum.—Not only are the R forms found in old laboratory cultures, but the S may be changed to the R antigen by more active means. If an S culture is grown in serum of an animal which has been immunised against the S form of the same bacillus, the S character gradually disappears from the culture and some, or all, of the bacteria become rough. At the same time the culture becomes non-virulent. This has been observed in part by several workers, Stryker, Walker, and others, and more definitely recently by Griffith, Reimann, Pitt, and myself. It is clear now that it is the actual antibody in the S anti-somatic serum which produces or accelerates this change, and that other antibodies do not have any effect. When the R somatic antigen has displaced the S, the S antiserum no longer has any somatic specific antibodies for such R bacteria. In spite of the lack of virulence of the R form it does not appear to lack vitality and vigour for vegetative growth.

CHEMICAL ANALYSIS.

It is in the attempt to solve the problem of the real difference between the S and R forms that the biochemist has stepped in and materially helped the concept of virulence.

Carbohydrate specific soluble substance.—The work of Heidelberger, Avery, Zinsser, and Landsteiner has introduced a new idea into the study of virulence. Their results are strongly supported on the theoretical side by Landsteiner's work on other kinds of substances which evoke antibodies in the blood of animals.

The virulent capsulated pneumococcus and the similar cultures of the capsulated so-called pneumobacillus of Friedländer when analysed chemically have been shown to contain a carbohydrate substance which is absent from the uncapsulated or "degraded" cultures which lack virulence. The capsule appears to consist largely of the carbohydrate or polysaccharide which has been called the "specific soluble substance," united with protein. It seems certain that this high development of the capsule is responsible for virulence and specificity and that the protein with which the carbohydrate is combined and which alone remains in the uncapsulated variety while sufficient for the life and growth of the microbe does not of itself determine high virulence. Not only is this the case, but the potent specific substances present in the blood of the immunised animal which counteract the effect of virulent cultures are not formed unless the carbohydrate or specific soluble substance is present in the immunising inoculum. This specific substance is not in itself, however, particularly toxic, nor does it evoke antibodies in the blood serum unless it is united with the protein substance which is always present, and which is apparently the most essential component of the bacterium as regards life and growth, apart from survival in the animal body and parasitism.

At first it looks as if the coincidence of capsule and virulence might be merely a restatement of the old observation that capsulated were more pathogenic than uncapsulated bacteria in certain species, and might be due to the old belief that the capsule protected the bacillus against phagocytosis by its physical interference with the process. There is, however, more in it than that, and there is a distinct advance in knowledge. Besides the satisfaction of having pushed the understanding of the matter back to the more intimate chemical structure, the capsule of different types of pneumococcus has been shown to be different chemically, and since the virulence of the types varies, so also the virulence may be said to vary with the chemical composition of the capsule. Type I. pneumococcus is much more virulent than type II., and the sugar obtained from it by analysis is different.

Moreover, there is very good reason to believe that a similar addition of a carbohydrate "specific soluble substance" to the protein of the bodies determines the difference in pathogenic activity and serological behaviour of the S and R variants of *B. typhosus* or *paratyphosus*, though in these bacteria there is no suggestion of a capsule being present.

Streptococci are a much more difficult problem, but they yield to chemical analysis essential differences in the composition of virulent and non-virulent cultures, and these have to some extent been correlated with the manner of growth, though in this group the superficial differences in the colonies are not quite the same, and still need further study before their significance is established. It seems as if the specific soluble carbohydrate substance comprised in the capsulated and S cultures was the essence of virulence and specificity which, as it were, gave a fillip to the bacteria and enabled them to cope with the conditions in the animal body.

A theoretical but not unimportant question is, how does the bacterium get this new substance? Is it merely due to a development and increase of an already existing part or function, or is it really an acquirement taken up whole and worked into its organisation like food and perhaps derived direct from the susceptible animal, or does it arise by the reaction of the bacterium to the juices and cells of the host? Certain bacteria are well known to increase in virulence when grown in normal serum in vitro.

The idea of an actual acquirement by the microbe from outside seems crude at first sight, but seeing that the capsulated state of the pneumococcus is not as a rule permanent and is often rather fugitive on artificial media which do not contain animal products, such as serum, the persistence of the capsule for the limited number of generations during which it usually continues in artificial media might perhaps be due to purely passive inheritance. Griffith, in 1928, using what appear to have been ample controls, found that if a living uncapsulated non-virulent pneumococcus were injected subcutaneously into a mouse together with a large amount of an emulsion killed by heat of a virulent culture of capsulated pneumococcus, then the mouse might die with virulent capsulated pneumococci in the blood of the same type as that of the heated culture. Neufeld and Levinthal, in the latter part of the same year and Reimann more recently, have confirmed this observation in essential points. This suggests that the presence of the specific soluble substance from the heated capsules enabled the uncapsulated or degraded culture to acquire virulence for the mouse and capsulation by assimilating the material from its environment. This is a remarkable feat and if fully corroborated will mean a great advance in the theoretical position. It is *not* intended to maintain that no parasitism can occur without these or somewhat similar changes in the capsular or somatic composition, but in the case of the more virulent microbes which have been investigated this appears to be so.

Immunity and prophylaxis in relation to variants.—In a few instances in which experiments have been made and a definite answer obtained, not only does virulence appear to be dependent on chemical changes or on the presence of special chemical constituents, but also the production of specific antibodies and immunity by inoculation of the bacteria, whether dead or alive, appears to depend on the same factor. Vaccines which do not contain bacteria endowed with the specific soluble substance are neither actively pathogenic nor of much value for prophylaxis.

CORRESPONDENCE OF IN-VIVO AND IN-VITRO CHARACTERS.

The thesis which I wish to support, therefore, is that there is often a correspondence in variants between in-vivo and in-vitro characters, and that capacity for parasitism can in certain cases be detected by examining the saprophytic characters. A virulent has often essential differences from a non-virulent which are recognisable apart from the animal body, and these differences are of a definite kind.

To take a concrete example, the *B. aertrycke* or *B. enteritidis* of food poisoning has so-called forms named in bacteriological jargon "smooth" and "rough" variants. These are distinguished usually in the following way: (1) By the R being agglutinable by salt solution and forming a deposit in broth culture with clear liquid above, whilst the S is not agglutinated by weak salt and in the broth culture is uniformly turbid. (2) By the smooth, shiny, round colonies of the S and the irregular, flattened, granular colonies of the R form. (3) By the production of different antibodies in animals by the two forms and their differential reactions with them. These serum reactions appear at present to be the most constant and serviceable in-vitro tests of the difference. (4) By chemical differences, on which the previous characters and especially the last appear to depend. This is probably the most fundamental character which has been discovered. (5) By the loss or gain of virulence. (6) There may be loss or gain of toxigenicity associated with the change in virulence, or toxigenicity may appear to be quite independent. (7) Associated with the last four characters, ability or inability to produce specific resistance in animals with dead vaccine, has certainly been demonstrated in some cases, and this property may be retained by the emulsions used as vaccines even after boiling or treatment with alcohol. (8) A further change or state associated to some extent with the foregoing is very prominent sometimes. Adaptation to a particular species of animal cannot be recognised in vitro, but as far as observation goes the R form is not capable of adaptation. In other words, a virulent adapted strain is always S.

It is fair, then, to claim that the study of virulence and all that it implies has made a definite step in advance in the last ten years by the convergence of pure bacteriology, epidemiology, and chemistry on the problem, and many new directions for future advance have been indicated and paths for investigation have been opened up.

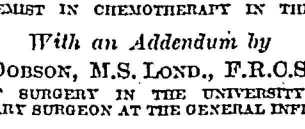
THE USE OF A
NEW QUINOLINE DERIVATIVE IN THE TREATMENT OF INFECTION.*

BY GEORGE ARMITAGE, *M.C.*, CH.M. LEEDS, F.R.C.S. ENG.,
SURGICAL TUTOR IN THE UNIVERSITY OF LEEDS AND SURGICAL REGISTRAR AT THE GENERAL INFIRMARY AT LEEDS;
AND
JOHN GORDON, M.D., D.P.H. LEEDS,
LECTURER IN BACTERIOLOGY IN THE UNIVERSITY.
In collaboration with
J. B. COHEN, PH.D., D.SC., F.R.S.,
EMERITUS PROFESSOR OF ORGANIC CHEMISTRY IN THE UNIVERSITY
AND
S. ELLINGWORTH, M.SC.,
RESEARCH CHEMIST IN CHEMOTHERAPY IN THE UNIVERSITY.
With an Addendum by
J. F. DOBSON, M.S. LOND., F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY AND SENIOR HONORARY SURGEON AT THE GENERAL INFIRMARY.

IN a paper[1] published by Browning, Cohen, Ellingworth, and Gulbransen, in 1926, a number of derivatives of anil-quinoline were shown to possess strong antiseptic properties.

They represent a new group of compounds, not hitherto used as antiseptics. These substances are crystalline solids which display a characteristic green reflex, and form in water blue and violet solutions. Since, however, the substance is used in very high dilution, the stains of its solutions on linen are easily removed by ordinary washing processes. Owing to the instability of these compounds towards hydrochloric and other strong acids, they are unsuitable for administration by the mouth, unless special provision is made for protecting them in their passage through the stomach.

The member of the group selected for these experiments was No. 48 of the series described in the paper and has the following formula:—



2 (*p*-Dimethylamino anil) 6 methyl quinoline methochloride.

It may be mentioned that two other substances (Nos. 52 and 59 of the series) were first selected for preliminary tests, but their almost complete insolubility in normal saline was a serious drawback.

---

* The work reported in this communication was done with the support of the Medical Research Council.

[1] Proc. Roy. Soc., B., 1926, c., 293.

Although slightly less powerful in antiseptic action than these compounds, No. 48 is much more soluble in normal saline. With the object of further increasing the solubility of the substance, an attempt was made to prepare a sulphonated derivative. This product, subsequently referred to as "48 S,"[1] although not the desired sulphonated compound, nevertheless proved on comparison with 48 to be superior in antiseptic power and to possess lower toxicity. The nature of the difference between 48 and 48 S is not at present known.

Antiseptic Tests.

Various amounts of a 0·02 per cent. (1 in 5000) solution of 48 S in normal saline were added to tubes of 1 per cent. peptone water and 20 per cent. serum-peptone water to give a series of concentrations from 1 in 50,000 to 1 in 1,000,000. These were inoculated with a loopful from a light emulsion of *Staphylococcus aureus* and *B. coli*. The tubes were incubated for 18 hours and subcultured on to agar plates. From the results of a number of tests the following figures represent a fair average for the minimum concentrations which effected complete sterilisation.

Anil-quinoline 48 S.

1 per cent. peptone water.		20 per cent. serum-peptone water.	
S. aureus.	*B. coli.*	*S. aureus.*	*B. coli.*
1/500,000	1/350,000	1/400,000	1/300,000

For comparison, simultaneous tests were made with acriflavine, which is a recognised efficient antiseptic in common use.

Acriflavine.

1 per cent. peptone water.		20 per cent. serum-peptone water.	
S. aureus.	*B. coli.*	*S. aureus.*	*B. coli.*
1/200,000	1/100,000	1/200,000	1/100,000

It will be seen from the above figures for 48 S that the potency is only slightly diminished by the addition of serum, in agreement with the observations previously recorded by Browning and his co-workers with respect to this group of substances.

With regard to the figures for acriflavine, although too great weight need not be attached to the differences in the values obtained (compare Browning and Gulbransen,[2] 1921), the comparison indicates that 48 S is more potent than acriflavine, and encouraged us to proceed with clinical tests.

Toxicity Tests.

The toxicity of 48 S was tested on rabbits by intravenous injection of a 0·5 per cent. (1 in 200) solution in normal saline, this forming an exacting test of the toxic action of the substance. Consideration of an extensive series of tests (75 rabbits) showed the mean dose tolerated by a 4½ lb. rabbit to be in the neighbourhood of 9 c.cm., equivalent in drug content to 45 c.cm. of the strongest solution later used intravenously in clinical practice. It will be seen, therefore, from the figures quoted later, that the clinical administration of the substance was far within the probable limit of tolerance for man.

Clinical Tests.

In view of the comparatively high antiseptic power and the relatively low toxicity of 48 S, it was decided, with the sanction of Prof. Dobson and the members of the honorary staff of the General Infirmary at Leeds, to test this compound in the treatment of all varieties of both local and general infective conditions. Its use at the above hospital has been extensive during the past 18 months.

Whilst it is impossible to give a detailed report of the in-patients (exceeding 1000 in number) treated with 48 S, or of a considerably larger number of out-patients, an attempt will be made to classify the cases treated according to the method of usage of the antiseptic, to state results, and to give a comparative impression of the value of 48 S. In certain sections, typical and instructive cases will be quoted.

It must be remembered how exceedingly difficult it is to assess the value of an antiseptic. There is no satisfactory bacteriological test; we have tried the method of taking swabs, growing cultures at intervals, and counting the number of colonies per unit field; but there are many fallacies and drawbacks in this method. Practically speaking, the only method is to judge the antiseptic on the clinical results obtained, and to compare the results with those obtained when using other antiseptics. Principally we have relied on this method. It has been advantageous, because the expenditure of a long period of time has been necessary, which is essential if a thorough clinical test of any antiseptic is to be made.

Groups of Cases in which 48 S has been Used.

A. It has been used as a prophylactic *antiseptic dressing* or *pack* in the treatment of: (1) Potentially infected accidental wounds and abrasions, as met with in the casualty department. (2) Extensive laceration of soft tissues, either alone or associated with fracture, requiring a thorough toilet of the wounds under general anæsthesia. (3) Circumcisions, amputation stumps, skin grafts. (4) The post-rectal space after operation for prolapse or excision of the rectum or after interstitial irradiation of cancer of the rectum with radium.

B. As a *local application* and *pack* in the treatment of gross infections: (1) Acute infections of the skin and subcutaneous tissues—i.e., boils, carbuncles, and cellulitis. (2) Suppurative hæmatomata. (3) Acute suppurative bursitis. (4) Acute suppurative lymphadenitis. (5) Ischiorectal and perianal abscesses. (6) Infected abdominal wall wounds—e.g., after operation for acute perforated appendicitis. (7) Fungating growths.

C. As an *irrigant* in the treatment of acute infections of bones and joints, such as acute infective osteomyelitis and acute suppurative arthritis.

D. As an *irrigant* in the treatment of chronic long-standing infections, comprising chronic infective osteomyelitis of the lower jaw, chronic empyemata, and suppurating hydatid cyst of the liver, after marsupialisation.

E. As a *genito-urinary irrigant* in cases of: (1) Acute and chronic cystitis. (2) Suprapubic bladder washing after cystotomy for enlarged prostate, vesical calculus, ruptured bladder and urethra, or malignant papilloma of bladder treated by diathermy. (3) Wheelhouse and Symes's external urethrotomy. (4) Perineal section for extravasation of urine. (5) Nephrostomy for pyonephrosis.

F. *Intravenous administration* in cases of septicæmia with a positive blood culture.

Clinical Results.

The following is a brief résumé of the clinical results obtained in each of the above groups.

Group A.—The strength of solutions used varied from 0·05 per cent. to 0·1 per cent. (1 in 2000 to 1 in 1000) in normal saline solution. As a modification we have tested the antiseptic in hypertonic saline—i.e., 2–3 per cent.—but this possesses no obvious advantage over normal saline. We are of opinion that the results obtained in this class of case are satisfactory. They are particularly striking in the case of the extensively lacerated wounds which are so common as a result of machinery or motor accidents. Cases of severe mutilation of the limbs associated with bad comminuted fractures have given excellent results.

---

[1] It is suggested that this substance should be called "quinanil."

[2] Brit. Jour. Exp. Path., 1921, ii., 95.

The antiseptic is a bland, non-irritant one, and can be used in abundance without any tissue damage or irritation. Its use can be prolonged; the granulation tissue which forms is firm, not swollen or œdematous, of the healthiest colour, and not protuberant.

Group B.—Here again the results have been satisfactory. In such cases as deep abscess cavities—e.g., ischiorectal—where it has been essential to pack the cavity most carefully and over a long period of time in order to ensure healing from the depth of the wound, there has been no indication of tissue damage or irritation. Epithelialisation from the edges of the wound is encouraged.

Group C.—In the case of acute infections of bones and joints, 48 S has received a thorough clinical test. The strength of solution used has varied, depending upon age and type of infection, from 0·01 per cent. to 0·1 per cent. (1 in 10,000 to 1 in 1000) in normal saline solution. The method of application has been by intermittent flushing of the wound, always keeping it moist by the aid of Carrel tubes. It is our opinion that in these cases the infection is more quickly brought under control, the separation of the sequestrum occurs more readily, and consequently the healing process is more rapid than has been our experience with other antiseptics generally employed in the treatment of these conditions. In uncomplicated cases, within 14 days of the original gutter operation for the drainage of the medullary cavity of the bone, the wound presents a firm, reddish pink, healthy granulating surface extending into the depths of the bone, and interrupted only by the yellow edges of the sequestrum in the process of separation.

One case of acute suppurative arthritis of the hip-joint is worthy of mention:—

The patient, aged 16 years, was admitted under the care of Mr. Dobson, complaining of excruciating pain in the left hip-joint of six weeks' standing. She was profoundly ill on admission, with temperature 103° F., respirations 28, and pulse 120. Examination revealed the fact that there was an acute suppurative arthritis, together with pathological dislocation of the left hip-joint. Exploratory arthrotomy was performed by one of us (G. A.). The head of the bone was excised and the joint drained. Continuous irrigation with 0·1 per cent. (1 in 1000) 48 S in normal saline solution was carried out. Immediately after operation the patient was profoundly ill, but apparently suffered no toxic effects from the large amounts of 48 S used.

To-day, ten months after her discharge from hospital, the wound is perfectly healed, and walking is almost devoid of limp. Examination of the joint reveals complete bony ankylosis in a position of 30° flexion and 30° abduction. X ray examination confirms the clinical findings.

Group D.—In this type of subacute and chronic infections the results are quite naturally not so striking as in the former classes, but nevertheless these cases have done well. The same strengths of solution in normal saline have been employed. In some cases 48 S has been used solely; in others its use has followed upon previous treatment with other antiseptics.

Group E.—As a genito-urinary antiseptic much weaker concentrations have been employed—namely, 0·005 per cent. to 0·05 per cent. (1 in 20,000 to 1 in 2000) in normal saline. The results have been encouraging. It should be remembered that the antiseptic is precipitated by concentration of salts such as are met with in normal urine, and in order to avoid this preliminary washing out with normal saline and boric lotion is carried out. Cases of bad cystitis in association with gonorrhœal and traumatic strictures of the urethra, enlargement of the prostate, and malignant papilloma of the bladder have responded satisfactorily.

A man, aged 58, was admitted to hospital under the care of Mr. Dobson, suffering from an extensive malignant papilloma of the bladder, associated with a stinking cystitis. Mr. Dobson performed a suprapubic cystotomy and found it impossible to proceed further on account of the cystitis. Suprapubic irrigation of the bladder with 0·05 per cent. (1 in 2000) 48 S in normal saline reduced the degree of cystitis in a remarkable manner within ten days.

Another man, aged 36, was admitted to hospital under the care of Mr. Dobson, suffering from rupture of the urethra in association with a fractured pelvis. Operation was immediately performed by one of us (G. A.). Perineal section was performed, but it was impossible to repair the tear in the urethra without preliminary suprapubic cystotomy and retrograde catheterisation. Eventually repair of the urethra was accomplished, and all the wounds left open. Irrigation of the bladder with 0·05 per cent. (1 in 2000) 48 S in normal saline was carried out during the patient's stay in hospital of ten weeks. To-day, eight months after operation, the patient is perfectly well, with no trace of cystitis.

Group F.—The nine cases of septicæmia treated by intravenous injection are as follows:—

(1) Six cases of acute infective endocarditis. No successes have been obtained. All the cases treated had a positive blood culture (streptococcus) and were all well advanced when they came under treatment. The initial intravenous dose was 20 c.cm. of 0·1 per cent. (1 in 1000) 48 S in normal saline solution, and this was repeated daily, increasing by 5 c.cm. on alternate days up to as much as 50 c.cm. Although all the cases proved fatal, it is significant to note that the temperature dropped after energetic administration of 48 S, and no toxic effects were manifested.

(2) One case of pneumococcal septicæmia and one case of staphylococcal septicæmia with bronchopneumonia. Both these cases terminated fatally.

(3) One case of streptococcal septicæmia with a positive blood culture, which recovered. This patient was under the care of Dr. J. le F. C. Burrow, to whom we are indebted for permission to publish the case.

The patient, a male aged 20, commenced his illness suddenly with a rigor. He continued for more than a week with severe backache and pains in the legs, high temperature, and shivering attacks. On admission to the hospital he was extremely ill, pulse 130, respirations 24, temperature 102°, pale, sweating, and semi-delirious. He made much complaint of pain in the legs, and especially in the region of the right hip, such that an acute arthritis of this joint was suspected. There were enlarged and tender inguinal glands, and an examination of the foot revealed a septic heel. A blood culture taken on the day of admission revealed the presence of a hæmolytic streptococcus.

It was decided to institute a vigorous course of intravenous antiseptic treatment, using a 0·1 per cent. (1 in 1000) solution of 48 S in normal saline. 20 c.cm. were administered at once, and on succeeding days for three days, when the dose was increased to 30 c.cm. and given for six days. Thus in ten days the patient received 260 c.cm. During this period the temperature was remitting daily between 103·5° and 100°. It then continued to intermit, gradually falling, however. On the tenth day after admission the temperature was normal, with an evening rise to 99·5°. Intravenous treatment was then stopped. Meanwhile the heel was incised, and a quantity of pus obtained. A large abscess of the right buttock appeared, and was drained on the tenth day after admission. A blood culture taken the next day was sterile. The patient's general condition was greatly improved, and the pulse was normal. His convalescence was uninterrupted for a fortnight, when he had a 48-hour pyrexial bout due to nasopharyngeal infection. A third blood culture taken immediately after this was also sterile. He was discharged after a short convalescence cured, and remains perfectly well to-day nine months afterwards.

Whilst we cannot attach great importance to the value of one particular case, we deem the above worthy of record.

Summary.

"48 S" is a slight modification of an antiseptic previously described by Browning and co-workers. The action of this antiseptic is only slightly diminished by the presence of serum, and the substance has a *relatively* high antiseptic titre, together with a low toxicity. The above clinical results indicate that 48 S is an antiseptic which is valuable in the treatment of all classes of surgical infections.

Addendum by Prof. Dobson.

Nothing is more difficult than to estimate the value of an antiseptic either in the prevention or in the treatment of septic processes. So far no scientific method has established itself as of value in such estimation, and one is left to depend entirely on personal opinion. Too often such opinions are valueless, being the outpourings of undiscerning enthusiasts. No surgeon who can recollect during the war the recurring waves of enthusiasm which greeted the advent of the latest antiseptic from "strong mixture" to plain soap can remain other than sceptical about another new remedy. But the search still continues for an antiseptic which, when applied in time, will prevent the development of sepsis and, when this process is established, will control and subjugate it. It cannot be maintained that this substance, 48 S, is such an antiseptic. Yet in my opinion it possesses qualities superior to those of any other similar substance of which I have experience. It is worthy of an extended trial, which I hope it will receive.

THE VALUE OF BISMUTH IN THE TREATMENT OF SYPHILIS.

By Prof. H. RITTER,
DIRECTOR OF THE DEPARTMENT OF DERMATOLOGY AND SYPHILOLOGY, GENERAL HOSPITAL ST. GEORG, HAMBURG;

AND

Dr. O. L. KARRENBERG,
CHIEF CLINICAL ASSISTANT.

BEFORE bismuth was definitely introduced for the treatment of syphilis in 1920 by the French workers, Levaditi and Sazerac, organised research had already been undertaken in Germany with a view to the use of this substance in the treatment of spirillas and related infections. These investigations, however, did not lead far because of the high toxicity of the preparations or compounds. As early as 1908 Uhlenhuth in the Imperial Hygienic Institutes treated trypanosome infestations with bismuth combined with arsenic. With the same end in view Ehrlich and Karrer in 1913 made a preparation of bismuth and arsenobenzol which unfortunately proved very unstable and therefore could not be used in practice. Not until 1919 did German writers publish a communication dealing with investigations on bismuth; in that year Kolle and Ritz used intravenous injections of colloidal bismuth in the treatment of syphilis in rabbits. This substance, however, proved extremely toxic and the investigations were therefore discontinued.

The studies of bismuth, begun in 1916 by Sauton and continued by Levaditi and Sazerac, who published their results in 1920, were first investigated in Germany in 1922 by Hugo Müller, who used the original French preparations. In the same year the first German antisyphilitic bismuth preparation was produced in Hamburg by the chemical firm of Tosse. This was "Bismogenol," and it was at once introduced into therapeutics by Doselaers. Other preparations of bismuth followed and were extensively investigated from the clinical side, and a large number were found to be active. A recent review by Hugo Müller and Kohlenberger shows that there are now about 17 German preparations of bismuth for the treatment of syphilis. Erich Hoffmann is justified in describing this state of affairs as harmful.

After six years of clinical observation and therapeutic administration we give our general conclusions on the value of bismuth treatment. There can be no doubt that the introduction of this metal represents a definite step forward in the treatment of syphilis, and the views of the few observers who contest this point (de Stefani, Villarejo, Bonnamour-Delore) do not essentially alter our opinion. Hugo Müller, to whom we owe an excellent summary on the technique of bismuth treatment, justly remarks that the various authorities who have made comparative studies of the therapeutic value of bismuth, salvarsan, and mercury have started from different standpoints. Some laid more stress on the rapid disappearance of the spirochætes when there were manifest symptoms and bismuth was the only treatment employed. Others attached more importance to the change in the reaction of the serum, or to the clinical progress, or to the rapidity of the disappearance of the obvious symptoms. Further, it must be remembered that different investigators used different preparations of bismuth of very varied composition, a fact which will certainly account for differences in the final verdicts. Lomholt states that different bismuth compounds are absorbed at very varying rates. This author has made an excellent contribution to the question of the chemical action and the fate of bismuth in the body, and in his most recent summary (1928) remarks upon the defective knowledge and erroneous ideas which exist on this subject. As the rate of absorption varies it follows that the effect must vary. "The decisive factor for the potency of action is the amount of bismuth metal which they contain and the rapidity with which they are taken up from the site of their deposit and pass into the body." The amount of bismuth varies extraordinarily—according to Langer as much as 20–100 per cent.—in the different preparations and also varies in different batches of the same preparation (Grumach, Engelhardt). The rapidity of absorption depends considerably on the method of application, on the solvent or suspension medium, and on the concentration and the size of the particles.

There is an extensive literature on the pharmacological, toxicological, and chemotherapeutic aspects of bismuth, especially in the treatment of syphilis, and it would lead too far to go into the details here. Engelhardt has recently published for the first time the results of researches, with methods to which no objection could be taken, on the excretion of bismuth from the human organism, with special reference to the significance of the various preparations and various methods of their use in the treatment of syphilis. This work calls for special attention.

Intramuscular Injection of Bismuth.

At the present time the method most generally adopted in Germany is the intramuscular injection of insoluble salts. Intravenous injection (Nadisan soluble, Nadisan colloidale, Sigmuth, Salluen, Wismulen, Bismuto-Yatren, Solvitron, &c.) has been practically abandoned, despite certain good reports (Memmesheimer, de Medina), primarily because of the great danger of shock and acute yellow atrophy of the liver, but also because the effect is in some respects weaker—e.g., on the serum reaction (Müller and Kohlenberger, Pautrier and Benech). In October, 1926, Hugo Müller sent a circular letter to German institutions where bismuth preparations were most in use, and he reports that over one-half of all the clinics employ the first German bismuth preparation—i.e., Bismogenol. We have used this preparation in our own clinic for the last six years, although we have also employed others. Our conclusions on its value for antisyphilitic treatment are based upon a relatively large number of clinical cases kept under observation for a comparatively long time.

Bismogenol is a suspension of a bismuth compound of a highly valent oxybenzoic acid in olive oil; it is thus a salicylate derivative, possibly identical with bismuth salicylate. Its content of bismuth is 50–60 per cent. or 0·05–0·06 g. per c.cm. Engelhardt has discussed the absorption of the preparation and has shown that Bismogenol is "the one bismuth preparation which is absorbed with the rapidity required." He further observed as a remarkable fact that Bismogenol is followed by a diuretic action which is not noted to such an extent after other bismuth preparations (a daily diuresis of 4–5 litres during the first ten days of treatment). There is a considerable literature on Bismogenol, including work by investigators from other countries as well as Germany. One great and indispensable therapeutic fact that emerges from all this work is that Bismogenol is, in the widest sense, an innocuous preparation. This is clearly shown by a case in this clinic which has been described by Prater.

> A patient had two injections of 10 c.cm. of Bismogenol at an interval of three days, the usual dose being 1 c.cm. As a result of this enormous overdose the patient had a mild stomatitis and a slight trace of albumin appeared in the urine, but there were no local signs of irritation. Six weeks

after the two injections a skiagram failed to reveal any deposit of bismuth.

Bismogenol is not subject to bacterial contamination. even if the vessel containing it is exposed to the air, Deselaers and Kafka have shown that Bismogenol remains sterile under these conditions, and we have been able to confirm their observation.

Experiences with Bismogenol.

Two reports have been issued from this clinic at the conclusion of a large series of investigations on the therapeutic effect of this preparation. One of us (Ritter) described his experiences one year after the introduction of Bismogenol, when he stated that the method of treatment with it showed remarkably good progress. There was not one failure in six cases of primary syphilis with a negative Wassermann. The reaction remained negative after the healing of the clinical signs. In other words, this preparation acted as an abortive agent on the disease. The effect of the exclusive use of bismuth in secondary and tertiary syphilis was good, the effect on the serum reaction being particularly noteworthy. In a work which appeared two years later Lauterbach was able to confirm Ritter's observations on the basis of a much greater clinical material. He also had at his disposal a series of patients who were treated by Bismogenol exclusively with excellent results. It is noteworthy that one patient who was treated for secondary syphilis with bismuth subsequently acquired a reinfection. Lauterbach also mentions especially the good effect on the Wassermann reaction (W.R.).

After six years' experience with this preparation our opinion of it has undergone no modification. Unpleasant effects have hardly ever been encountered, especially not the "embolia cutis medicamentosa" (exanthematica, bullosa, gangrænosa) described by Freudenthal, Nicolau, and Nagel. Freudenthal, who described it first, designated it as a "local embolic Bismogenol-exanthem," but it has not been observed in the many thousands of injections undertaken during the course of a year. Other skin eruptions have been described by authors such as Buy, Wenniger, Grön, Müller, Hudelo, and Ravaut) after the administration of other bismuth preparations as well as after Bismogenol (Kerl), but we have not observed any of them. There is, however, one exception in a patient who is still in the clinic and whose case should be described on account of certain important points.

A female patient, aged 19 years, suffering from obvious syphilitic signs (papules, spirochæte-positive) had received an intramuscular injection before admission. The nature of the preparation could not be ascertained. Otherwise there had been no treatment. On admission the W.R. was strongly positive. An intramuscular injection of 1 c.cm. of Bismogenol was given. The next day the patient had a high temperature and a generalised dermatitis of a scarlatiniform type, of the characters with which we have been familiarised by Jähnke and Schäcker and Pawlas. Venesection was performed and Ringer's solution was infused, and in a few days the manifestations subsided, but the rash returned after eight days in a milder form, although the patient had no more Bismogenol. After this relapse had disappeared 1 c.cm. of Bismogenol was given again, whereupon the temperature rose once more and there was a repetition of the rash. There was a very strongly positive intramuscular reaction with 0·1 c.cm. of Bismogenol, and a pad soaked in Bismogenol could not be kept on the skin of the forearm for longer than ten minutes because of the intolerable burning and blistering. Thus there was in this case an intense hypersensitiveness to Bismogenol. The behaviour of the skin to other preparations of bismuth has not so far been tested. The patient tolerates salvarsan exceedingly well. After the subsidence of the second outbreak of the rash the W.R. was completely negative, and the syphilitic manifestations were completely cured.

This case provides one of the best proofs of Ritter's contention of the importance of toxic exanthemata as non-specific curative factors in syphilis.

By-effects were seldom seen. That most frequently c[illegible]s a bismuth line, more especially in [illegible] had the bismuth at the conclusion ma[illegible]ment—in other words, patients [illegible]ged 30, [illegible] liable to absorb the drug [illegible]on, suffer in large amounts. The line, however, was invariably slight. A fully developed stomatitis was seen very rarely, but we always insist upon a very thorough hygiene of the mouth during an antisyphilitic treatment. We have never seen any disturbance of the intestinal tract nor any derangement of the nervous system, and damage to the kidneys was also very rare. In no case was there any permanent injury; at most some epithelial cells could be found in the urine, but without albumin. Naturally, the urine must be most carefully examined during a bismuth treatment. None of the patients ever complained of pain at the site of the injections, which were never objected to, even by the most sensitive patients.

The Relationship of Bismuth to Salvarsan and Mercury.

As with every new form there were at first some optimists who wished to place bismuth on a higher plane than salvarsan in the treatment of syphilis. Ritter uttered a warning against this in his first work, and the experience of the following year, based upon comparative researches, showed that he was correct. Lomholt laid great stress on the far-reaching pharmacological and toxicological similarity of bismuth and mercury. From a therapeutic standpoint both metals produce a rapid saturation of the body with a large amount of the metal which, however, is well borne. The saturation persists for a very considerable time, Owing to this similarity Lomholt is of opinion that bismuth may replace mercury in the treatment of syphilis, because the by-effects of the latter drug are much more severe, but that bismuth can never replace salvarsan. Hugo Müller, on the other hand, states that bismuth appears to be superior to mercury—apart from grey oil and calomel—but that otherwise it is not correct to speak of a complete substitution of mercury by bismuth. Bismuth cannot be regarded as irreplaceable in the sense that salvarsan is, because the latter holds a unique position in the campaign against syphilis as a human plague.

Naturally, different views on this matter are more or less subjective and are not capable of proof. Our own opinion, based upon experience, is that bismuth is definitely superior to mercury. Since using bismuth in our clinic we have not once given an injection of mercury. The question of inunction treatment is, however, not under consideration here, and we are also of opinion that the substitution of bismuth for salvarsan does not come under discussion. Each of these drugs has its own definite indication which mainly follows the natural course of the disease. To a certain extent the two drugs coincide at a certain point, and then they should be given in combination, for one of the most important advances in the modern treatment of syphilis appears to be the realisation that each case must be treated individually and any scheme should only be adhered to loosely. In choosing the form of treatment we must reckon to a very great extent on the coöperation of the powers of immunity possessed by the body, and we must be most careful not to disturb the state of immunity which is the resultant of the play of infection and defence. Our opinion agrees with that of other authors (Buschke, Langer, Nonne) that bismuth is well adapted for this purpose.

It was mentioned above that, at first, cases of primary chancre with a sero-negative reaction were treated with Bismogenol in an abortive manner, and that as a matter of fact permanent cure was attained. This method was at that time applied exclusively for the purpose of testing the Bismogenol, but it should not be adopted in practice. In this type of case salvarsan is absolutely indicated and should be used in combination with bismuth as an abortive treatment. Salvarsan will remove the actual state of infectivity with the maximum rapidity; its sudden powerful action may prevent the infection of the entire body. By means of the bismuth a long persistent effect over a certain period is assured, and this acts as a prophylactic against relapses. The further the syphilis extends the stronger is the indication for bismuth in its treatment. Although some authorities advocate abortive treatment by means of salvarsan alone, and some indeed assert that combination with other remedies weakens the effect of the salvarsan (Stühmer, Fantl), the great majority take their stand on the combined treatment of secondary syphilis. Gougerot goes even farther when he says "after the first year salvarsan treatment is no longer imperative." The longer the syphilis persists the less becomes the necessity for salvarsan and the greater the indication for bismuth. The whole tendency of the schemes of treatments inclines towards the latter, and in further combination treatment iodine takes the place of salvarsan. The only exception to this is in cases where the cerebro-spinal fluid is positive in the stage of late latency, when a combined malarial treatment should be undertaken. At the conclusion of the malarial course a further course, in the form of an abortive treatment, should be given.

The very great value of bismuth, especially for the treatment of the later stages of syphilis, is undoubtedly due to some extent to the fact that it is a mild and yet durable remedy which serves as a preparation for more intense courses of treatment. It is never followed by the severe reactions which are often seen in the later stages after salvarsan. Bismuth is never contra-indicated at the beginning of an antisyphilitic course, with the one exception of early abortive treatment, whereas there are many contra-indications to salvarsan in the later stages. On the other hand, bismuth is indispensable in those cases which are hypersensitive towards salvarsan or mercury.

A Scheme of Treatment.

In the course of years a definite scheme of treatment has been worked out; it is tabulated herewith. No attempt will be made to compare this scheme with the many others which have been published from different clinics, but one point should be emphasised in the words of Jadassohn, "it is certainly not desirable to adhere slavishly to a scheme, which is by no means unnecessary in syphilis . . . but every scheme affords the opportunity of individualising."

We have adopted the following as divisions of the different stages of syphilis.

1. *Incubation Period.*—Three to five weeks. Variations from six days to six weeks.

2. *Primary Syphilis.*—Stage of primary chancre.

3. *First to Second Stage of Syphilis.*—As primary stage; but there is a positive Wassermann reaction without any clinical signs of generalisation.

4. *Secondary Syphilis.*—Manifest clinical signs of generalisation; spirochætes present; Wassermann reaction positive. In rare cases both these signs may be negative. Duration of secondary period generally four years, chiefly depending upon the state of immunity.

5. *Tertiary Syphilis.*—Manifest clinical symptoms coming on after the secondary period with positive Wassermann reaction. The presence of spirochætes is exceptional, and their absence the rule.

6. *Latent Syphilis.*—A general term for stages wherein the syphilis only manifests itself by a positive serum reaction, but no definite clinical signs are present. Its subdivisions are: (*a*) Early latency: three to five years after infection. (*b*) Late latency: after three to five years subsequent to infection.

The fundamental condition of treatment must be accurate diagnosis—i.e., the demonstration of spirochætes or of a positive Wassermann reaction after the exclusion of other causes. Observation may in itself be treatment.

(A) *Incubation Period.*—Observation.

(B) *Primary Syphilis.*—Administration of large doses of salvarsan in three courses as soon as the diagnosis has been verified. First day: 0·45 g. neosalvarsan. Second day: 2 c.cm. Bismogenol. Third day, 0·45 g. neosalvarsan. Fourth day: 0·45 g. neosalvarsan. Fifth day: 2 c.cm. Bismogenol. Sixth day: 0·6 g. neosalvarsan. Seventh day: 2 c.cm. Bismogenol. Eighth day: 0·6 g. neosalvarsan.

This is to be followed every four or five days by 0·6 g. of neosalvarsan and 2 c.cm. of Bismogenol twice weekly.

Total amount of salvarsan	5–5·5 g.
" " Bismogenol	20 c.cm.

Twenty-four hours after the first injection a W.R. test must be done and repeated every eight days during the treatment and 14 days after its termination.

Second Course of Treatment (30 days later).—First day: 2 c.cm. Bismogenol. Second day: Interval. Third day: 2 c.cm. Bismogenol. Fourth day: 0·45 g. neosalvarsan.

Then two injections of 0·45 g. neosalvarsan in the week and two injections of 2 c.cm. Bismogenol. In the following week two injections of 0·6 g. of neosalvarsan and of Bismogenol. Total amount as in first course of treatment. W.R. test as in first course and then at the end of the treatment and subsequently every month.

Third Course of Treatment (90 days later, last course).—The scheme is as in previous course; the W.R. tests included. If the reaction is negative no further treatment is given. Observation for possible later internal manifestations.

First to Second Stage.—Treatment as in secondary syphilis.

(C) *Secondary Syphilis.*—The treatment must avoid the production of a severe Jarisch-Herxheimer reaction on the one hand and of inadequate treatment and waste of effort on the other.

First Course.—Same scheme as second course of primary syphilis, with Wassermann test at the end of the course. Potassium iodide should be given in the interval until the second course begins.

Second Course (30 days later).—Identical with the first course.

Third Course (90 days later).—Similar to the other courses.

If the reaction remains negative after the first course no further treatment is required after the third course; but monthly tests should be made at first, and later on quarterly and half yearly. The cerebro-spinal fluid should be examined after three to five years. If this is positive treatment should be given as for latent syphilis. If, on the other hand, there are variations in the reaction during the subsequent courses further treatment will be required until the Wassermann reaction remains negative, and then two more courses should be given subsequently.

(D) *Tertiary Syphilis.*—It may be accepted as a principle that the skin, by the production of tertiary syphilitic manifestations, indicates that it has attained a very intensive degree of allergic sensitiveness and that the case in question is especially characterised by a great esophylactic action.

(*a*) *Simple skin cases*, without complications in the heart, vessels, bones, and especially in the cerebro-spinal fluid, can be relieved by Bismogenol injections, oral administration of potassium iodide, Zuttman's solution, and general tonics. Careful observations of internal organs and central nervous system is necessary; if these are healthy prolonged iodide administration should be given after the disappearance of skin symptoms, but observation must be continued. The Wassermann reaction must under no circumstances be forced to become negative.

(*b*) *Skin Cases Combined with Diseases of Internal Organs.*—The principle should be that of individual treatment of each case with reference to age and general condition. Long treatment with potassium iodide, inunction, and bismuth should be tried before resorting to salvarsan, in order to avoid the dangers of the latter. In detail:—

(1) *Heart and Blood-vessels.*—In addition to Bismogenol and potassium iodide a subsequent course of neosalvarsan is given in small individual doses (0·15–0·3 g. per dose), until a total quantity of 5 g. has been given, according to the amount of toleration, and repeated as in secondary syphilis.

(2) *Kidneys.*—Bismogenol and mercury, potassium iodide, and neosalvarsan are given with general care.

(3) *Liver.*—Salvarsan, potassium iodide, Bismogenol, and dietetic treatment are given, together with general care.

(*c*) *Skin Cases Combined with Disease of the Cerebro-spinal Fluid.*—Combined malarial treatment (compare work of Ritter-Völker). Contra-indications: Simultaneous presence of a renal or hepatic disorder; this must be dealt with first and then malarial treatment instituted. Simple syphilitic meso-aortitis is no contra-indication to malarial treatment.

(E) *Latent Syphilis.*—The examination of the cerebro-spinal fluid plays an essential rôle, especially in establishing the existence of a late latency, and also in treatment. A series of investigations has shown that:—

(*a*) In the stage of early latency the results of examination of the cerebro-spinal fluid are very varying.

(*b*) The cerebro-spinal fluid may become normal spontaneously if it has already been pathological.

(*c*) Energetic treatment is capable of making the fluid normal.

(*d*) As a rule the state of the cerebro-spinal fluid apparently remains constant for two to three years after infection (Meirowsky).

In the following scheme of treatment the term "well treated" signifies a method of treatment which corresponds to our directions for primary or secondary syphilis. "Insufficiently treated" signifies cases which have not undergone the courses prescribed by our scheme, or cases which have had inadequate dosage or where the intervals between the injections have been too long.

(1) *Early Latency.—Positive W.R.* (*a*) Well treated; repetition of treatment as for secondary syphilis. If there is no change, malarial treatment (relative indication as a result of resistant serum reaction).

(*b*) Insufficiently treated: treatment as for secondary syphilis; otherwise procedure as in (*a*), when the Wassermann reaction remains positive.

Negative W.R.—(*a*) Well treated; no further treatment, careful clinical observation, and eventually examination of cerebro-spinal fluid at onset of late latency.

(*b*) Insufficiently treated: consider whether diagnosis of syphilis was correct; no treatment; procedure as in (*a*).

(2) *Late Latency.*—For every further decision in these cases it is necessary to obtain the result of the examination of the cerebro-spinal fluid.

Positive W.R.—(*a*) Well treated:—

(1) Positive W.R. in cerebro-spinal fluid: combined malarial treatment.

(2) Negative W.R. in cerebro-spinal fluid: Salvarsan treatment contra-indicated. Generally mild treatment with Bismogenol and potassium iodide is advisable, with careful observation and subsequent repetition of the lumbar puncture. Combined malarial treatment is given when there is a relative indication owing to resistant Wassermann test.

(*b*) Insufficiently treated.

(1) Positive W.R. in cerebro-spinal fluid: combined malarial treatment.

(2) Negative W.R. in cerebro-spinal fluid: very careful observation: procedure as in (*a*), subsection (2).

Negative W.R.—(*a*) Well treated.

(1) Cerebro-spinal fluid positive: after the exclusion of any possible error in this test malarial treatment (for which this is a most precise indication).

(2) Cerebro-spinal fluid negative: no treatment; careful observation.

(*b*) Insufficiently treated.

(1) Cerebro-spinal fluid positive: malarial treatment (most precise indication).

(2) Cerebro-spinal fluid negative: consider whether the diagnosis of syphilis was correct; no treatment; careful observation.

(G) *Congenital Syphilis.*—Treatment should only be given when the diagnosis of an existing syphilis has been absolutely established.

(1) Mother obviously syphilitic during pregnancy: good prophylactic treatment; careful clinical and serological observation of child without treatment.

(2) Mother with latent syphilis: no treatment during pregnancy or first discovery of syphilis in mother towards end of pregnancy, and no treatment in a prophylactic sense.

(*a*) Child clinically healthy: serological examination to be repeated often; treatment as for secondary syphilis if Wassermann reaction is positive; salvarsan, inunction treatment, and later Bismogenol.

(*b*) *Child evidently syphilitic*: treatment as for secondary syphilis (neosalvarsan 6–10 mg. per kilo body-weight, thus beginning with 0·02, later 0·03 g.–0·05 g.; subsequently inunction treatment, 0·5 g. each dose *in four parts*, then bath, interval of two days, repetition; about 30 rubbings and duration not more than five minutes. The ointment should be made to penetrate rather than be merely rubbed over. As an introduction to the treatment in pemphigus give sublimate baths (1 g. of corrosive sublimate dissolved in 100 c.cm. of absolute alcohol; 20 litres of water to be added to this *mixture*, at 35° C.; duration of bath 30 minutes). If there is any mercurial dermatitis the drug must be given internally thus:—

℞ Hydrarg. iodat. flav. .. .. 0·01
Pulv. gummos .. .. 0·5
Sig: One to three powders daily.

Careful observation must be *made of the stools*. The decision regarding the quantity of the drug which is to be administered must be based entirely on the constitution of the infant. As a rule there should be three courses of treatment in the first year, two courses in the second year, and one course in the third year.

3. Late congenital syphilis: as a rule treatment should be as in tertiary syphilis. When clinical signs have disappeared an examination must be made of the cerebro-spinal fluid.

(*a*) Negative Wassermann reaction:

(1) Cerebro-spinal fluid negative: no treatment.

(2) Cerebro-spinal fluid positive: malarial treatment, definite indication.

(*b*) Positive W.R.

(1) Cerebro-spinal fluid positive: malarial treatment, very strong indication.

(2) Cerebro-spinal fluid negative: no treatment, clinical observation, indication for malarial treatment relative.

This scheme offers a mode of treatment which is free from danger; but treatment must always be entirely conditioned by the state of the patient.

ELECTRICAL TREATMENTS IN ACUTE CONDITIONS.

BY C. B. HEALD, C.B.E., M.D. CAMB.,
M.R.C.P. LOND.,
PHYSICIAN-IN-CHARGE OF THE ELECTROTHERAPEUTIC DEPARTMENT OF THE ROYAL FREE HOSPITAL.

FOR many years electrical currents have been employed only in convalescent, or chronic conditions, and little or no thought has been given to the possible benefits they might bring to patients suffering from acute illnesses such as pneumonia, peritonitis, septicæmia, collapse, or shock.

This is very natural in view of the history of the development of electrotherapeutics. One of the earliest forms of electrical treatment was the "static machine." In this treatment the patient was near a big, unwieldy apparatus on an insulated glass-legged table, and was frequently the recipient of sparks and purposeful small shocks. With such a setting the mind does not even associate anything sedative, much less a sick room. Then came the so-called "Faradic currents," with their stimulation of muscle contractions, and the far more painful "Galvanic" contractions. Ionisations had their day, and were frequently carried to the point of toleration by the patient; even ultra-violet light, with its stinging erythema, and diathermy with its ability to coagulate and burn, all helped to make electrical treatment a process that required somewhat of robustness on the part of the patient.

It is, therefore, not in the least surprising that the possibilities of electrical currents in acute illnesses should have failed to receive recognition or support from those who had experience of its earlier and more common uses.

Since ultra-violet light has become more and more familiar to practitioners the interest in physical means of treatment has grown, and with this growth has come a realisation that, with suitable technique, this current can be so employed that it either can function as an intense counter-irritant or be so truly sedative that it is the treatment of choice for relieving pain in acute burns of the youngest babies. In America for some years Eaton Stewart at New Haven has been employing diathermy in all stages of pneumonia; and Crile at Cleveland has been using this current actually during and immediately after serious operations as a means of reducing operative and post-operative shock. Although I am not aware of any literature published in England on the subject of electrotherapeutics in acute ailments, it is clear that Eaton Stewart's pioneer work is beginning to bear fruit, for the medical wards of St. Bartholomew's are wired for diathermy, and, at the West Middlesex, diathermy in pneumonia is now practically a routine procedure.

In a paper I read at the School of Medicine for Women in 1926, my experience of diathermy in pneumonia was limited to six cases in all; one acute, in a child of 6, one unresolved pneumonia, and four broncho-pneumonias in patients varying from the age of 3 to 85. At that time, beyond having treated a somewhat similar number of burns with ultra-violet light, the only recent or acute conditions I had treated in large numbers were fractures and lymphangitis. The high percentage of these cases that received genuine relief and help have undoubtedly accounted for the rapid growth in the number of acute conditions that I have been called upon to assist during the last two years, both in hospital and in private. Among these cases there are pneumonias of all kinds and descriptions, acute and spreading lymphangitis, peritonitis with temperature and profuse and offensive discharges, acutely septic joints and, last but not least, burns of all degrees.

Selection of Treatment.

In the primary selection of electrical treatment for any acute condition the first essential is to endeavour to visualise the actual pathological condition and the physiological response most desired; and then, with the knowledge of the physiological effects of various currents and current strengths, selection can be made without difficulty, and suitable technique employed with confidence. The simplest type of case to consider is the severe recent injury, and one case in particular comes to my mind.

The patient, a male adult railway worker, had had his pelvis crushed and fractured, and was suffering severe pain, and the region of the injury was greatly swollen and œdematous. The pathological condition here was, therefore, injured, and hypersensitive nerve-endings, muscle spasm and effusion each reacting adversely on the other.

The desired physiological response would therefore obviously be reduction of muscle spasm, of pain, and of swelling. Now the direct current has at its positive pole certain physiologically proved characteristics—namely, anelectrotonus, or the depression of sensitivity in nerve tissues; cataphoresis, or the carrying of water towards the cathode; and the removal of the demarcation currents of injury (Hermann) in muscle. This current, therefore, if exhibited with a technique that brings out these physiological attributes, is uniquely suited for such a case. And so it proved.

Large pads of gamgee wrung out in 1 per cent. zinc sulphate solution were placed over and near the pelvis, especially over the lower abdomen, which was the site of the greatest pain and swelling; an indifferent electrode was applied to a forearm, so that the current could flow in the direction of the lymph stream, and a current of two to four milliampères was utilised for 15 to 20 minutes. On this occasion the apparatus used was what is known as a galvano-set, but in bed cases the new portable direct current apparatus, known as the Medelect, is even more satisfactory. After the first treatment pain was so much relieved that some natural sleep could be obtained, and within two or three days pain and muscle spasm were gone and swelling rapidly diminishing. I have given technical details of this method elsewhere.[1]

Diathermy in Poliomyelitis.

Perhaps the next most simple condition to consider from the pathological point of view is an acute attack of poliomyelitis. Here we all have a vivid picture of an inflamed and congested area of the spinal cord, the inflammation leading to such congestion that the life of the anterior horn cells becomes precarious, many may die, and some recover with difficulty. To restore the normal physiological condition of the cord we would, if we could, at once reduce the congestion and allow circulation in arterioles, capillaries, and venules to carry out its ordinary work of nutrition. We know, however, that the affected parts are deeply placed in a bony canal, and that fomentations on the skin would have no chance of effective action. So we turn to the late Sir William Savory's great maxim, given in his famous lecture, when he came into the lecture theatre, looked at the students, said "Gentlemen, rest all inflamed parts," and for the remainder of the hour never uttered another word. There is not an authority on this ailment that does not lay down emphatically that electrical treatment in the acute stages must never be employed. When, however, we come to their recommendation for electrical treatment in the later stages, these are all of a "stimulative" nature, and the possibility of fomenting the spinal cord region has obviously never been considered. If the inflamed spinal cord lay within reach of fomentations, as does, for example, lymphangitis in an arm, fomentations would undoubtedly be added to the treatment of "rest."

Can electricity provide a current free of any trace of stimulation of such a nature that it can, to some extent, act as a fomentation for so deeply placed and protected a structure as the spinal cord? The answer is, it can.

In diathermy, thanks to the work of d'Arsonval and others, it has been shown conclusively that, when current reversals occur at rates over 50–100,000 per second, all stimulation ceases. Now modern diathermy machines have current reversals from a half to three million times per second according to the way they are made; so even those with only 500,000 reversal have passed the stimulation range many times.

The diathermy current is closely allied to the wireless wave, and on passing through tissues they readily become degraded to heat waves, identical with the heat waves given out by a fomentation, a hot water bottle, or the water in an arm bath—with this difference, that their initial structure is such that they can pass through all kinds of tissues, whether conducting or non-conducting, and where they meet relatively poorly conducting tissues, such as bone, their change into heat waves is more rapid than in such vascular structures as muscles. It is therefore obvious that in diathermy we have a current capable of fomenting the neighbourhood of the injured spinal cord without any vestige of stimulation.

Although these facts have been emphasised, both in France and in England, the prejudice against using electrical treatment during the acute stage of poliomyelitis still remains—because electrical treatment calls up pictures of muscle contractions and stimulation admittedly to be avoided at all costs. In consequence of this very natural prejudice, I have only had experience of two cases during the really acute stages, and, with the known vagaries of this complaint, the mere fact that their pain disappeared rapidly and recovery was practically perfect does not, unfortunately, enable me to claim any specific benefit from the treatment. It is, however, justifiable to say that the clinical response corresponded with the theoretical considerations previously formulated. The technique would be simple and would consist of applying over the spine where the lesion is known to be a metal electrode, covered in two thicknesses of lint, wrung out in super-saturated saline solution. This electrode should be at least 6 in. to 9 in. square, and a similar electrode is placed over the soft parts of the abdomen. The actual size of the electrode should be determined by the area of the soft abdomen. A current of almost 1 ampère is passed for 20 minutes, and, if the pads are bandaged on with a thin rubber bandage, uniform contact will be secured, and the risk of burning be reduced to zero, as pads of these sizes, if carefully applied, will carry nearly twice this current, even in quite a young child, for considerable periods. One has, therefore, a large margin of safety.

Diathermy in Pneumonia.

Exactly the same pathological and physiological considerations arise in cases of pneumonia, bronchopneumonia, and allied conditions. I will not give clinical notes of the cases that I have treated with diathermy, since my experience of the benefits of this current entirely confirms the work of Eaton Stewart, and his book, "Diathermy with Special Reference to Pneumonia," is a sane and well-balanced treatise on the subject. The technique I employ for diathermy in pulmonary cases is precisely similar to the one just referred to, except that where patients are collapsed or suffering from difficult and hampered breathing the pads are slipped under each armpit, and the patient's elbows are held gently against the pads by nurse and doctor, so that the arm can follow respiratory movements without hindering them in the least. This method entails a minimum of disturbance of the patient.

One recent case of Dr. W. Byam's may be cited as illustrating several points in the application of diathermy in the early stages of pneumonia. In this patient, a man of 73, with the sputum yielding a nearly pure culture of pneumococci and the lungs showing the early signs of consolidation, the chief anxieties were restlessness, continuous cough, and absence of any desire to sleep. During the first application the cough ceased, the patient fell asleep and had six hours' further restful sleep after the treatment ceased.

---

[1] Brit. Med. Jour., 1934, i., 743.

I wish to dwell at some length on certain effects of the diathermy current which are not, in my opinion, related to its action as a sedative fomentation. One of the first things that strikes the patient, the observing practitioner, and the technical expert is the restful after-effect, hours of quiet sleep often following the very first application. Another easily made clinical observation is a curious change in the type of respiration, which from being like an inverted V becomes definitely more smoothly undulatory in type. Also in delirious and wandering patients the delirium frequently ceases abruptly during treatment, and the patients converse intelligently.

Physiological Action of Diathermy.

Breathing that becomes deeper and more physiological in type, sleep or rest for periods far longer than could be accounted for by any single fomentation; an improved pulse volume—all these reactions are suggestive of some specific action of the diathermy current on the sympathetic system.

It has long been taught that diathermy acts only by heat, and has no specific action due to its wave-length. The very name of diathermy supports this theory. As I have said, however, diathermy currents are practically identical with ordinary wireless waves (one machine I have has a wave-length of 365 metres). This current, therefore, does not primarily belong to the heat, or infra-red, portion of the ether scale, but it does make itself manifest as heat *after* it has been absorbed, and to appear as such these waves must have first been absorbed and then changed to heat waves.

It is known that other parts of the ether scale such as radium, X rays, and ultra-violet light, have each their own peculiar specific effects, and it is reasonable to presume that diathermy, which only differs in the length of its waves, also has its own specific effects, even if these cannot be immediately recognised.

This being so, the question arises whether there are any clinical indications, other than those already given, that diathermy currents have any specific action, and, if so, on what particular structures do they exert this action.

Let us once more turn to poliomyelitis, but this time to the chronic case, with its cold blue atrophic lower limb. Give such a child diathermy from over the anatomical position of the injured cord to the abdomen three times a week (never at first to the affected limb), and at the end of 12 treatments the limb will be showing signs of increased warmth and improved trophic condition, not only during the actual treatment, but between treatments. What mere heat could do this?

Diathermy is recommended by Osler as the treatment of choice in hyperpiesia, but the effects obtained are not shown on the sphygmomanometer, but in the diminution of cramps, of head pains, giddiness, and indeed of those symptoms of sympathetic derangement of which the patient complains as the cause of his difference from normal health. In Crile's clinic in Cleveland diathermy is equally employed for cases of shock and collapse where the blood pressure is below normal.

For years I have been in the habit of giving abdominal diathermy to those cases of wasting debility associated with gastro-intestinal symptoms, and I use this current as a powerful aid to effective ultra-violet light treatment. If it be allowed that diathermy does have its own specific action, and that this action on the sympathetic system is of the nature of a "governor," there is nothing strange in finding it successfully employed, both in hyper- and hypopiesia, for are not the vaso-constrictor and vaso-dilator fibres themselves fibres of the same sympathetic system? With the acceptance of this theory of its action the observed effects on rest, breathing, &c., in pneumonia and allied conditions are understandable and logical, as are the effects of this current when employed in cases of shock, collapse, and affections of digestion.

It will, I think, be generally agreed that the pathology of shock and collapse is intimately associated with extreme derangement of the sympathetic mechanism. The physiological need is therefore restoration of tone and balance in this system. What is ordinarily done for the patient suffering from severe shock? Heat is applied in all kinds of ways, every effort and device that can be thought of to raise the blood pressure is resorted to; yet I have not heard of, or seen, except in the single case of Crile's clinic in Cleveland, diathermy being employed in shock and collapse if only as a supplier of heat. If my arguments in favour of this current having its own special field of activity carry conviction, what a sphere of research is opened!

A point that is often raised when discussing the advisability of utilising diathermy in serious conditions is that the application of the pads will disturb the patient. In employing diathermy, general metabolic saving can be effected without any disturbance of the patient if electrodes are either bandaged on to the sole of each foot, using the same technique as described above, or to each hand, forearm, or upper arm. It is clear that this method, especially when applied to the feet, constitutes practically no disturbance to the patient. It also obviates any risk of burning, for the portable machines are not capable of giving sufficient current when such a large resistance as leg to leg is in the circuit as will lead to burning, and firm bandaging, such as can be effected in these positions, is the best protection of all. For the last seven years in my department at the Royal Free Hospital infants with poliomyelitis have been treated not only without any trace of burn but with highly encouraging results.

Sepsis and Ultra-violet Light.

In the foregoing survey I have endeavoured to show the principles, pathological and physiological, that make me select either the direct current or diathermy, and I have said nothing about the treatment of septic conditions, such as peritonitis after operation, or other grave infections, such as septicæmia. Here ultra-violet light has a genuine field of usefulness. I have dealt elsewhere with its action in raising the hæmobactericidal power of the blood, but here I may perhaps refer to the possibilities of local treatment of septic cavities or sinuses, such as occur in peritonitis or osteomyelitis.

Provided there is adequate drainage, or, rather, adequate access, I have found that local ultra-violet light, by means of sterilised quartz rods attached to a water-cooled Kromayer lamp, act entirely locally and with a rapidity and effectiveness that suggests almost a special reaction under these conditions. It is easy to formulate reasons why there is no general reaction, even to intensive local treatments; for instance, it is possible to argue that the local reaction is on all fours with milk sterilisation by the mercury-vapour lamp, where thin films of bacteria-containing fluid are brought into close contact with the actual bactericidal rays of this current.

A case of necrosis of the lung provides an interesting illustrative case of this type. This patient, a child aged 6, under the care of Dr. Chodak Gregory, was almost in extremis, when doses of light from a mercury-vapour lamp, at 30 in. for three minutes, were applied to the huge offensive necrotic hole in the chest. From the first application there was a favourable local reaction which rapidly increased, and in a few days the patient was out of danger and made an uninterrupted recovery. In this case the treatment and the response were so obviously connected that the amelioration was clearly the work of the light on the local condition.

Burns.

There is one condition which I have left to the last, partly because it interests me acutely and partly because I can advance no theory that explains satisfactorily why the treatment I now invariably use is so uniformly successful in its results. The condition to which I refer is burns.

For these I employ extremely small doses of ultra-violet light from a full-sized mercury-vapour lamp at 30 in. for two minutes; the burnt surface being either covered with liquid paraffin or ambrine, the remainder of the limb being protected from the rays. The liquid paraffin or the ambrine are highly fluorescent in the presence of ultra-violet light, and therefore diminish the dosage materially, and change the incident ray to another which they give out. The second patient I ever treated by this method had third-degree burns of both breasts, and when doses of light were first administered was in a state of collapse from the repeated anæsthetics and/or pain of the dressings. From the first application of ultra-violet-light re-dressings were practically painless; recovery was uninterrupted, and the patient has since successfully suckled two babies at the breast.

An investigation of burns treated by this method is now proceeding, and I will content myself by recording the facts that pain is more rapidly alleviated by this treatment than by picric acid, tannic acid, liquid paraffin, or ambrine alone, and that healing is more rapid, and that the resulting scar is better. All this happens with a current which can readily cause erythema and desquamation of the epithelium. If the paraffin technique is not employed the pain and healthy formation of elastic epithelium is not helped. It seems to be essential, and the fluorescence of this material would appear to have something to do with the results. This question, and the question whether diathermy has a specific action on the sympathetic, must be left for future research.

Conclusion.

I will close with a plea and a warning. The plea is, that when electricity is to be used in acute illness it should not be asked to do the impossible by being called upon only when the patient is semi-moribund. The warning is, that practitioners should avoid employing persons not medically qualified for giving electric treatments in acute illness unless they have themselves mastered the technique. To emphasise the reality of this warning, I will mention a case recently brought to my notice where the spreading septic condition had been checked by competent and successful surgery, only to be thwarted by an injudicious dose of ultra-violet light, resulting in œdema, with consequent hindrance of the previously adequate drainage, and finally death.

It is therefore justifiable to claim that advances in our knowledge of electrical current now enable us to:

1. Eradicate, when so desired, all stimulative and irritative characteristics inherent in certain types of current.
2. Produce currents with true sedative effects.
3. That in consequence the direct current can now be used with benefit to reduce pain and spasm in recent fractures, &c.; diathermy employed in pneumonia, shock, collapse, &c.; and ultra-violet light in burns and septic conditions, with advantage to the patient.

SALFORD ROYAL HOSPITAL.—At the annual meeting it was stated that the number of patients treated during the year was 49,600. In order to provide the purchase-money for the premises recently acquired for the hospital extension, and to reduce the large bank overdraft, the board of management had been reluctantly compelled to sell hospital investments amounting to over £31,000. Plans have been approved for a paying patients' hospital with 45 beds—a complete block with separate nursing staff and servants. As a result of motor accidents during the past year, 90 in-patients and 144 out-patients were treated in the hospital, at a cost of £514, and the amount contributed was only £34. The expenditure of the hospital in excess of income for the year was £13,200.

Clinical and Laboratory Notes.

FOREIGN BODIES AND NASAL CARRIERS OF DIPHTHERIA.

BY A. H. G. BURTON, M.D. LOND., D.P.H.,
MEDICAL OFFICER OF HEALTH, ILFORD;
AND
A. R. BALMAIN, M.D. LOND., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH.

NASAL carriers of diphtheria bacilli are common, but foreign bodies in the nares, producing a carrier condition, are rare.

Scholes[1] has seen five cases of unilateral nasal discharge (containing virulent diphtheria bacilli) due to foreign bodies in the nose. In THE LANCET in 1922 Keen and Carson[2] described two cases of nasal diphtheria due to foreign bodies, and Barnes[3] one case, due respectively to shoe buttons and a piece of rubber (but it is not stated that the virulence of the organisms was determined). Also Forbes[4] described a case of nasal discharge due to a button in which the organisms were tested and found to be virulent. In none of these cases does a Schick test appear to have been carried out.

Three Cases out of Nearly Two Thousand.

Some idea of the comparative rarity of the condition may be gathered from the fact that out of a series of 1968 cases admitted to the Ilford Isolation Hospital the condition has only been found on three occasions. The following case is therefore of interest:

A boy, aged 9 years, was found at routine medical inspection at school to be suffering from an unilateral nasal discharge excoriating the nares. A swab was taken which showed morphological Klebs-Löffler bacilli (K.L.B.), and the boy, at the request of the parents, was removed to the Isolation Hospital on June 11th, 1929, and placed in a separation ward for observation. A swab from the right nostril was positive for K.L.B., and from the left nostril negative. The organisms found in the nose were tested on a guinea-pig and found to be virulent. The boy was Schick negative, showing that he was a true diphtheria carrier. On careful examination a foreign body was located far back in the right nostril, and with some difficulty was removed with forceps. The foreign body consisted of a rolled piece of material which proved to be a maker's tape from the back of a man's tie. The nasal discharge ceased after the removal of the foreign body. Swabs from the right nostril were positive for K.L.B. two days later, but became negative 11 days later, and were again negative after a further seven days.

Examination of the maker's tape showed that the tie had been purchased in Exeter, and on inquiry it was found that the boy had visited Devonshire in July, 1928, and at that time had been seen playing with the piece of tape, and also with a small stone which he had pushed up his nose. The stone was recovered from the nose, and it was thought that the tape had come down also. The boy returned home in October, 1928, and in January, 1929, the nasal discharge began. He had been taken to a doctor, who had thought he had a polypus. He had never had diphtheria; no diphtheria cases had occurred at the house in Devonshire and none in Ilford. He had only been in Ilford 11 weeks when he was examined at school; previously to that he had resided at Hackney. On inquiry at Hackney no diphtheria cases could be traced as being due to him.

Two other cases have occurred in Ilford:—

A girl, aged 3½ years, admitted to the Isolation Hospital in June, 1928, with an unilateral nasal discharge of two months' duration. Morphological diphtheria bacilli were found in the culture from the nasal swab. A pea was removed from the right nostril. The nasal discharge ceased and two further nasal swabs proved to be negative, but a Schick test was not carried out in this case, nor was an investigation made of the virulence of the organisms.

A boy admitted to the Isolation Hospital in 1914 suffering from a nasal discharge containing morphological diphtheria bacilli. A shoe button was extruded from the right nostril after a period of seven months, but a Schick test was not carried out in this case nor was the virulence of the organisms tested. A brother of the boy was, however, admitted to hospital at the same time with a sharp attack of faucial diphtheria, and it is probable that the boy with the foreign body and nasal discharge was a carrier of diphtheria bacilli and infected his brother.

The case which we have recorded in some detail is of interest, as the question arises as to whether the boy was Schick negative because he had immunised himself by infecting his nose with diphtheria bacilli from the foreign body, and so administered to himself small doses of toxin.

Immunisation through the Mucosa.

De Stella,[5] in 1903, showed by experiments on animals that the nasal mucous membrane in diphtheritic rhinitis secretes an antitoxin which neutralises the diphtheritic toxin, and so prevented toxic symptoms resulting. This is probably what happened in the case described. If this is so, a further interesting question arises as to whether it would not be practicable to immunise persons against diphtheria through the nasal mucous membrane instead of by subcutaneous injections.

Peters and Allison[6] have experimented with intranasal immunisation against scarlet fever by spraying the nose every other day with scarlet fever toxin, with the result that a number of Dick-positive persons became Dick negative, while in others the Dick-positive reaction was much reduced in area. It seems theoretically possible to devise a method of intranasal immunisation against diphtheria which would give still more satisfactory results.

If immunisation against diphtheria could be effected through the nasal mucous membrane it would also throw some light on the hypothetical latent immunisation by which natural acquired immunity is supposed to be obtained, for it would appear probable that it is through the nose that such immunity is acquired. It can be supposed that most persons on few or many occasions inhale diphtheria bacilli which produce sufficient toxin in the nose to cause, by repeated doses, immunity to develop, but not enough to cause an attack of diphtheria.

ORBITAL ABSCESS FOLLOWING REMOVAL OF TONSILS AND ADENOIDS.

BY G. NORMAN CLARK, M.B. ABERD.,
HOUSE SURGEON, BELGRAVE HOSPITAL FOR CHILDREN, LONDON.

A GIRL, aged 4 years and 7 months, had her tonsils guillotined and adenoids curetted, and was discharged from hospital the next day. Four days after the operation she was brought up again looking very ill with a temperature of 102·8° F., marked swelling of the right eyelids, proptosis, and restriction of the movements of the eyeball in all directions. On the following day some swelling of the left eye appeared. A deep incision was made below the right supraorbital border, but no pus was found. Two days later there was no improvement in the condition, the eyeball was displaced markedly outwards, movements were very limited, and there was much swelling of the orbital tissues and injection of the conjunctiva. The incision was deepened inwards, and on introducing a sinus forceps pus was found lying deeply outside the lamina papyracea of the ethmoid, the bone here being bare. The patient had an uneventful convalescence. On discharge the movements of the eye were full, there being only slight ptosis. The *Staphylococcus aureus* and the Friedländer's bacillus were cultured from the pus.

I have to thank Mr. Cecil Wakeley for permission to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS.

AT the meeting of this Section on Nov. 1st, with Dr. ASHLEY DALY in the chair, the subject of discussion was

AVERTIN ANÆSTHESIA.

Dr. JOSEPH BLOMFIELD said that avertin was a tri-bromine-ethyl-alcohol, a white crystalline substance which dissolved in water only with difficulty up to 3·5 per cent. The makers had now produced it in a fluid form, in which every cubic centimetre contained 1 gramme. The dose recommended was 0·1 g. of avertin per kg. of body-weight (or two-thirds of a gramme per stone weight). The technique of injection was simple; the solution was run slowly into the rectum by means of a soft tube, which should be passed for four inches; owing to the varying reaction of different patients to anæsthetic drugs it was important that the anæsthetist should be present when the solution was introduced. When a patient had had no more than 4·0 g. he might be unconscious enough to go to the operating theatre. The need for care in dosage was emphasised by a reported case which occurred in this country. A man, aged 25, was prepared for the operation of radical cure of inguinal hernia. Before the avertin he had morphia gr. ¼. The degree of anæsthesia induced by the avertin was not sufficient for the operation, and he was given gas and oxygen. The operation was duly carried out, and he left the theatre apparently in a normal state; yet he never recovered consciousness, and he died eight hours later. The dose given was a safe one, and the autopsy revealed no reason for the death. Dr. Blomfield thought that some undetected error must have been made in the case; nothing comparable to this fatal unconsciousness had come within his own experience.

The induction of unconsciousness following avertin was extraordinarily satisfactory, continued Dr. Blomfield; it seemed to be as pleasant a way of going to sleep as could well be imagined. He had not seen any accompanying excitement. One nervy young man said he felt a strong temptation to try to expel the tube from his rectum; but he was not a good subject for any anæsthetic, since on several occasions he had had ether which he disliked very much, and which made him vomit. Usually respiration became somewhat depressed—i.e., rather shallower and slower—and the condition was not unlike sleep, except that there was somewhat less colour in the face, and stertor easily developed. The blood pressure fell by 10 to 15 mm. of mercury. Often when a patient had avertin unconsciousness the corneal reflex was absent, and yet, if a painful stimulus were applied, a reflex movement occurred, and this would be repeated on the first cut with the knife. The speaker therefore did not rely on absence of the corneal reflex. The best means of knowing that the patient did not need any more anæsthetic was to give strong ether vapour to inhale; if this was taken quietly, without holding of the breath, it was safe to begin the operation. The muscles were relaxed, the breathing was quiet, the circulation was quiet, and the blood pressure was only slightly lowered. Of his own cases, only about a quarter had had a satisfactory anæsthesia with avertin only. Much depended on the patient and the operation. The kind of patient who had given him greatest satisfaction with avertin was the feeble elderly person who was having some such operation as gastrostomy—the kind of patient who sometimes failed to recover after inhalation anæsthesia. Often these old subjects required no other anæsthetic than the avertin. The next satisfactory class were cases of exophthalmic goitre. On the average, patients who had avertin could be assured of two to four hours' unconsciousness, which was not so deep that it need deter one from using avertin in cases where there was likely to be blood in the air passages. The coma was not so deep as after paraldehyde. He had used avertin for dissection of tonsils, and in other cases where there was sure to be blood in the mouth, and he never had any anxiety on that score.

Summing up, Dr. Blomfield described avertin as a very valuable addition to the drugs available for the anæsthetist. But he thought no attempt should be made to use it as a routine anæsthetic, especially as it was desirable for the anæsthetist to see it actually administered. It gave a very pleasant induction of anæsthesia, and was especially valuable for patients who had had trouble with, or intensely disliked, every other anæsthetic. Also, it added enormously to the safety of such operations as those for exophthalmic goitre.

A Series of 106 Cases.

Sir FRANCIS SHIPWAY said that in the first four or five cases he had anæsthetised with avertin he had used the solid form, while in the remainder of his 106 cases the fluid preparation was employed. He had found that a strength of 2·5 per cent. gave a more even absorption and a more gradual induction than a 3 per cent. solution; also excitement was less likely—though so far he had never seen excitement in any case in which the drug was used. Children might well be given 3 per cent. strength, since they did not retain it as long as adults. Sixty-six of his patients were males, ranging in age from 12 to 72; the ages of the 48 females were from 15 to 66. The patients had also been given morphine and atropine, or morphine gr. ¼ and scopolamine gr. 1/150. Sir Francis thought that body-weight was an unscientific guide to dosage; habits, occupation, and environment must all be taken into account. The alcoholic, the active, and the highly-strung person reacted relatively badly. He had used avertin in 17 abdominal operations, including gastrostomy, and in 20 of his cases it had sufficed by itself. In 91 cases gas and oxygen was used in addition, and in 10 other was added to the gas and oxygen; 3 received chloroform and ether; and 1 was given chloroform for removal of a growth of the tongue by diathermy. Induction he had found to be quiet and smooth, and usually rapid—so rapid, in fact, that unconsciousness sometimes came on in the middle of a sentence. The patient was placed on his side, as a precaution against obstructed breathing. Patients were always of a good colour with avertin, and he had not had need of any respiratory stimulant. If one should be needed, he thought carbon dioxide the best. After avertin the pulse-rate was slightly increased, and the blood pressure fell by about 10 mm.; the maximum fall he had so far observed was 30 mm. The corneal reflex was usually just present, but in ten cases it had been absent altogether. Among tests of the depth of anæsthesia were the application of picric acid or iodine to the operation area, the application of towel clips to the skin, and depression of the lower jaw. Analysis of the urine of these patients revealed no albumin or blood. One man who had his inguinal hernia operated upon developed bronchitis; he had been given gas and oxygen in addition. On three occasions the avertin to be used was found to be unsatisfactory; it was decomposing. After induction of anæsthesia with avertin the rectum was not washed out. The patient could be aroused for any purpose—e.g., to take fluid—and thereafter relapsed into sleep, sometimes for as long as 12 hours. Fatal cases in which the drug was used showed fatty heart muscle and cirrhosis of the liver.

Sir Francis regarded avertin as a safe means of induction, providing an excellent basis for anæsthesia and especially free from after-effects. It was contra-indicated for patients having a rapid fall of blood pressure, and for people with renal disease. Otherwise it was the most delightful and excellent method of anæsthesia induction he had seen.

Discussion.

Dr. JAMES YOUNG (Edinburgh) said that the impressions he received concerning avertin in 150 cases conformed with those already expressed at the meeting. He noted particularly the ease of induction and the comfort of the patient. The method seemed peculiarly suitable for gynæcological cases, because there was no post-operative sickness. After operations on the pelvic floor vomiting was very liable to burst the stitches. In a series of 154 cases under his observation there were two deaths, but in neither could the avertin be held responsible. He had now reduced the preliminary dose of morphia to gr. ¼, and this had proved an advantage, though the patient required more inhalation anæsthesia.

Dr. I. N. LEWIS referred to his use of avertin in 28 cases. It was most effective in the case of patients whom he could classify as soft thyroids. Possibly a stimulus to the patient's metabolism might hasten excretion of the drug. Hypothyroid cases recovered from avertin more quickly than others. He had had no unpleasant incidents in his cases.

Dr. H. E. G. BOYLE said he had not had any experience with avertin, but he would have thought that giving patients heavy doses of morphia and scopolamine beforehand put them in a position of danger. He suggested that a much smaller dose of avertin than what was now prescribed might be used as a means of premedication.

Dr. COUX said that a drawback to the use of avertin alone was the length of time it had to be given before the operation. In nearly all his cases he had to use some supplementary anæsthetic.

Dr. C. F. HADFIELD commended the method by which avertin was introduced to the profession in this country by the makers, who recognised its danger unless under expert control.

Dr. R. A. RAMSAY spoke of the efficacy of carbon dioxide as a restorative when a case seemed to be doing badly.

Dr. Z. MENNELL said he had not any great experience of the method, but it was one which he disliked for the ordinary healthy person. The cyanosis which occurred with it meant that attention had to be given to the airway, and certainly administration of the drug should not be left to nurses. He did not think the corneal reflex was a guide to the depth of anæsthesia, any more than it was in the case of hedonal. It would be wrong to use avertin as a routine anæsthetic, and also, he thought, for tonsil and adenoid removals, and for big operations on the mouth.

Mr. C. HOPE CARLTON asked whether in Graves's disease the bromine in the avertin compensated for the absence of iodine in the patient.

Dr. HUGH PHILLIPS spoke of the possibility of employing avertin in association with spinal anæsthesia.

Mr. GEOFFREY KEYNES said that avertin had been used in many of his cases, and he had hoped it would enable other anæsthesia to be dispensed with, especially in abdominal operations. In a case of gastrectomy the avertin was combined with a local infiltration of the abdominal wall, and in a dose of only 0·08 g. per kg. of body-weight it proved so satisfactory that it seemed to be an ideal form of anæsthesia. He had long felt that for gastrostomy nothing but a local anæsthetic was needed.

SECTION OF OTOLOGY.

HISTORY OF THE MASTOID OPERATION.

IN his presidential address to the Section of Otology on Nov. 1st Mr. W. M. MOLLISON traced the history of the mastoid operation from the seventeenth century to modern times. The first reference in the literature was in 1649 when Johannes Riolanus wrote recommending the trephining of the mastoid process. In its earliest days the operation was performed for the relief of tinnitus, or in order to make a new Eustachian tube. The first operation on the mastoid designed to promote the evacuation of pus was carried out in 1740 by Petit, who used a trephine. In 1776 Jasser operated for suppuration by boring a hole in the bone, through which he forced lotion in order to drive out the pus; this procedure he repeated on 12 succeeding days. The operation fell into disrepute after it had been performed on the Danish Court physician, Berger, for tinnitus and deafness, with a fatal result. It took centuries to evolve a satisfactory method of opening the mastoid process for the release of pus. The radical mastoid operation dated from about 1889, when Zaufal published the operation generally known as Stacke's operation. In the light of present-day knowledge it was clear that at first many patients were subjected to the radical operation quite unjustifiably, and that the total amount of hearing lost because of these initial errors was incalculable. Fortunately, however, this dark period did not last longer than about seven years. The last phase, dating from 1897, was a conservative one, since the aim of modern surgeons was to save the ossicles and thus to preserve the hearing. Mr. Mollison pointed out that there were many different methods of performing the conservative mastoid operation. The bone was removed from the posterior wall far enough to allow of meatal flaps; the outer attic wall was removed to drain the attic and observe the presence of cholesteatoma and the condition of the ossicles; some removed a bridge; others left just enough to support the membrane. If the attic wall was not removed the aditus was exposed and the condition of the incus investigated; if necrosed the incus was removed. The position of the perforation and the amount of hearing were determining factors in the choice of operation. A number of suggestions had been made with the object of facilitating the healing of the wound left by the operation. The wound could be left open and allowed to granulate; it could be allowed to fill with blood clot. Some flushed it by means of the Carrel-Dakin apparatus and others closed it by secondary suture or filled it with bismuth and iodoform paste before suture. Bone-grafts had been used after irrigation with Carrel-Dakin fluid, and zinc ionisation was yet another method of after-treatment. The main object should be borne in mind, and this was to secure a thorough opening of all accessible cells.

In conclusion, Mr. Mollison said that the real triumph of the mastoid operation would lie in the successful treatment of all cases of acute otitis media, if need be by the Schwartze operation, thus eliminating chronic suppuration. In the future the need for a radical mastoid operation in any case would be regarded as an indication of failure.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT a meeting held at Liverpool on Oct. 25th, with Dr. G. W. FITZGERALD in the chair, a paper on

TUBERCULOSIS AND PREGNANCY.

was read by Mr. LEYLAND ROBINSON. It was based, he said, upon the answers to a questionaire submitted to experts in tuberculosis, 200 of whom sent replies. This questionaire dealt with the effect of pregnancy on latent, quiescent, and active types of disease, and discussed the treatment, special attention being paid to the value of therapeutic abortion. The main conclusions were as follows: (1) childbirth is always a danger to the phthisical woman; (2) all forms of pulmonary tuberculosis are affected by parturition—latent, arrested, or otherwise; (3) in the interests of the individual it is desirable that reproduction by phthisical patients should be regulated —sterilisation is neither desirable nor probable; (4) special supervision ought to be made for the treatment of pregnant women with tuberculosis in sanatoriums and adequate accommodation provided for labour and the lying-in period, (5) phthisical women who are pregnant should receive the ordinary sanatorium treatment, including artificial pneumothorax; (6) therapeutic abortion has a limited field of usefulness and should be restricted to special cases of early disease in early pregnancy; (7) special antenatal supervision by a skilled obstetrician is an essential part of the routine treatment; (8) the child must be isolated; (9) lactation must be forbidden.

The PRESIDENT said that his impression was that tuberculous women improved during pregnancy but rapidly grew worse in the puerperium.

Dr. C. R. SCHOFIELD (Southport) spoke of the difficulty of getting a pregnant tuberculous woman looked after. He had just had a case of a young girl who developed acute pulmonary tuberculosis and a tuberculous larynx within a month of term. Eventually he did an induction for her but she was dead in three months. He had seen some tuberculous mothers improve during and between pregnancies and others killed by pregnancy. Much seemed to depend on the stage of the disease.

Dr. J. E. GEMMELL (Liverpool) recalled a case of a woman who showed evidence of phthisis after a miscarriage. After years of treatment she was declared cured (physical signs and X rays) and allowed to become pregnant. At the sixth month the disease reappeared and the patient was dead in two months.

Dr. W. W. KING (Sheffield) mentioned a case which improved during pregnancy and rapidly went downhill after delivery. He urged that the diversity of tuberculous disease be remembered. He quoted statistics from an American hospital showing that in comparable cases under comparable conditions only 3–4 per cent. more pregnant than non-pregnant women showed advance in the disease.

Dr. F. H. LACEY (Manchester) quoted figures from the literature showing that the mortality was very little higher in pregnant than in non-pregnant women, but that it was in the first six months after delivery that the prognosis was worst. He thought that tuberculous disease of the larynx or the presence of toxæmia made the prognosis very serious.—Dr. J. W. BURNS quoted a case of marked improvement during pregnancy under sanatorium treatment.—Dr. PERCY MALPAS said that in a recent German symposium the consensus of opinion was against induction of abortion in all three stages of the disease.—Dr. J. H. WILLETT had interrupted a pregnancy early where it occurred in a healed case.—Prof. DANIEL DOUGAL (Manchester) thought Mr. Robinson's paper would become the standard one on the subject. He added that Rist held that pregnancy was inimical to phthisis and thought that this was due to hyperthyroidism asociated with pregnancy. Rist thought highly of artificial pneumothorax and allowed marriage if sputum was free from organisms two years after operation.

Mrs. DOBBIN CRAWFORD read a note entitled

A Useful Perineal Dressing.

After trying many dressings for perineorrhaphy and colporrhaphy wounds, she had come to use the following emulsion of acriflavine: acriflavine, 0·10; liquid paraffin, 76·65; white wax, 3·25; distilled water 20·00. An interval of 24 to 48 hours was allowed to elapse, and at the latest on the third day—the day on which the aperient was given and before the bowels were opened—dressing was begun with a narrow strip of gauze about three inches long soaked in the emulsion, and by means of forceps laid upon the colpo-perineorrhaphy wound. The dressing was renewed after each micturition, and the results had been satisfactory. The dressing had also proved itself of value after confinements in which there had been great bruising of the vulva. Mrs. Crawford had found the emulsion an ideal perineal dressing. The paraffin kept the perineum dry, the flavine kept it clean or cleared up any incipient infection, while the whole was soothing to the patient.—Dr. BURNS agreed about the value of acriflavine. He had found a 1–1000 watery solution useful for swabbing out an infected pelvis and had noted that it had a considerable hæmostatic effect on an oozing surface.

Mrs. CRAWFORD also showed a uterine tumour for diagnosis; Dr. J. W. BRIDE (Manchester) reported a case of hydatid of the broad ligament; and Mr. A. MCMURRAY described a hydatid in the pelvis.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING IN MANCHESTER.

(Concluded from p. 929.)

SECTION OF VENEREAL DISEASES.

DIAGNOSTIC AND OTHER ERRORS IN QUESTIONS OF VENEREAL DISEASE.

Colonel L. W. HARRISON said that a young wife had developed a Bartholin's abscess. The husband had previously been cured of gonorrhœa; nevertheless, he was informed that he had infected his wife. Careful investigation showed that the causative organism of the Bartholin's abscess was *B. coli*. Had this investigation not been carried out the case would have had all the makings of a marriage wreck. The subject of his paper had been suggested to him by the consideration of errors of which he quoted a typical example. Ordinary balanitis was sometimes diagnosed as gonorrhœa, and he knew of a case where a mother had been requested to remove her son from a public school because of such a mistake. Dislike of examining the penis at close quarters accounted for many cases where a syphilitic chancre at the meatus or within the fossa had been diagnosed as gonorrhœa; it was common to see cases of tertiary syphilis where the patient denied having had a sore but admitted gonorrhœa, and it was reasonable to suppose that the discharge had been due to an intra-urethral chancre. Omission of microscopical examination led to many cases of simple urethritis being treated as gonorrhœa. A vaginal discharge was often due to other causes than the gonococcus. A diagnosis should not be made on the strength of a naked-eye examination nor on a single microscopic test. A urethral discharge was sometimes due to the breaking down of a prostatic abscess, and this had at times been diagnosed as gonorrhœa on the appearance of the discharge or on the faulty staining of microscopical specimens. Epididymitis, especially if accompanied by a urethral discharge, often suggested gonorrhœa to the practitioner to the exclusion of infections with *B. coli* or *B. tuberculosis*. He had known some cases of right-sided gonococcal epididymitis diagnosed as appendicitis; the absence of rigidity of the rectus and tenderness of the cord at the ischio-pubic ramus should have indicated the nature of the lesion. Colonel Harrison emphasised the value of the microscope, a culture tube with properly made medium, and the complement-fixation test as aids to diagnosis, but pointed out that they did not make unnecessary a careful clinical examination. He thought that innocent prostates and seminal vesicles were often condemned for trouble which lay in the anterior urethra. Proper cleansing of the urethra was an essential preliminary to expression of the prostatic secretion for microscopical examination, as otherwise this might become mixed with pus cells derived from the anterior urethra. In syphilitic infections he deplored the pernicious practice of commencing treatment of early cases on a mere suspicion. Promptitude in commencing treatment was certainly important, but not so important as certainty of diagnosis. He quoted an article by Dr. J. H. Mitchell entitled Menace of the Slightly Positive Wassermann Reaction, where this author related cases in which a faulty diagnosis had been made on a weakly positive W.R. alone, or in conjunction with non-specific dermatoses, the result being the firm establishment of that intractable disease "syphilophobia." He had always taught that if a report of a serum reaction as positive was not supported by the clinical data, another specimen of blood should be examined. Extragenital chancres, he pointed out, were a common source of error. He remembered the case of a chancre of the tonsil being enucleated, which was later sent to hospital as a case of measles, the true diagnosis being reached only when the eruption did not clear up in the time usual for measles. A frequent mistake was to assume that all abnormalities were syphilitic in patients with a positive W.R. Tertiary syphilis of the tongue had led to many epitheliomata being overlooked; on the other hand, gummata of the testicle had been removed under the impression that they were new growths. The tendency in nervous diseases was to think of syphilis and in cardiovascular disease to forget it. In skin rashes occurring during syphilitic treatment the greatest caution had to be exercised; one must consider most seriously whether the rash was not due to the arsenic and on no account continue with the arsenical treatment until it had been clearly established that arsenic was not the cause; neglect to adopt this precaution might easily lead to the death of the patient. Bismuth also, it must be remembered, might cause a troublesome dermatitis. In venereal diseases one must look for and gather all the evidence, and then sift it with judgment and with common sense.

Discussion.

Dr. DAVID LEES said that Colonel Harrison emphasised chiefly the type of case in which venereal disease was wrongly diagnosed rather than that where the diagnosis of venereal disease was overlooked. In any class of patient the medical attendant hesitated to consider such a diagnosis, and still less to suggest it to the patient; his mind was blurred by the moral issue involved. He cited the case of a boy of 8 years with marked synovitis of both knee-joints where the doctor had negatived the diagnosis of inherited syphilis on the high moral standing of the parents; it eventually transpired, however, that the child had been adopted. A common diagnostic error was made in ulceration of the leg; any lesion of this type which was not associated with definite varicosity of the veins, with an atrophic skin, or depressed circulation with trauma, or, in women, with a history of uterine sepsis, must always be suspect. There were many subjects of inherited syphilis who showed few, if any, of the classical stigmata. He quoted a case where a wrong diagnosis of osseous sarcoma was corrected by tracing the family history of the patient's mother, who had a syphilitic ulcer of the leg. He also deprecated the practice of commencing treatment of syphilis on mere suspicion. It was little short of malpraxis to treat the diagnosis of syphilis lightly. Clinical, bacteriological, and serological methods of diagnosis were now so accurate that their intelligent use should make a diagnosis possible in nearly every case. The most difficult ones were perhaps those of herpes genitalis, especially after treatment by strong antiseptics. He deprecated the therapeutic test as a method of diagnosis, and in particular the use of the provocative injection until the end of the fourth week. He noted the frequency with which tuberculous lesions manifesting themselves after an attack of gonorrhœa were diagnosed as sequelæ of gonorrhœa, and quoted instances where the urethroscope was an essential aid to diagnosis.

Dr. MARGARET RORKE said that she had frequently encountered a *B. coli* infection simulating gonorrhœa, especially in the young bride and where there had been brutal coitus. She pointed out that a salpingitis, accompanied by gonococcal urethritis, was not necessarily gonorrhœal; she had seen many cases where the infection was tuberculous. She deprecated the use of the term "weakly positive Wassermann," recommending that the term "doubtful" should be used instead. A patient either had or had not syphilis; treatment should not be administered until the diagnosis was established.

Sir ROBERT BOLAM suggested difficulties in diagnosis presented in lichen planus and in Bazin's disease. A venerealogist should be a fine physician with a broad outlook.

Dr. GORDON WHITEHEAD cited a case of carcinoma of the penis simulating a primary sore. He emphasised the importance of examining the marriage partner in cases of discharge where the gonococcus could not be demonstrated. The lesson of this discussion was that a thorough and complete examination of every patient was imperative.

Dr. A. C. **Roxburgh** described a series of cases where the diagnosis was not obvious, including indurated herpes simulating a primary sore, and a syphilitic rash mistaken for eczema.

Dr. **Wheeler Hart** recalled cases of discharge from the use of too strong antiseptics, and endorsed all that had been said about early and complete treatment.

Preparations of Bismuth in Therapy of Syphilis.

Dr. **Svend Lomholt** (Copenhagen), who opened this discussion, said that bismuth was now adopted by practically all syphilologists throughout the world as a substitute for mercury. It was more efficient and less toxic than the older remedy. Bismuth could be administered only by muscular injection, since it was but slightly absorbed through the skin and intestines. The number of preparations now on the market made it difficult for the doctor to make a right choice. Very little was known with regard to the effects of bismuth on the syphilitic organism and the syphilitic infection itself. The bismuth content of the blood at any time during treatment was always small; therefore bismuth did not act directly on the spirochætes. Dr. Lomholt quoted Levaditi's theory of the formation of a compound of bismuth with protein substances, this compound being toxic to spirochætc. In Dr. Lomholt's experience the best effect in treatment is obtained when large quantities of bismuth are introduced, producing in the organism a high bismuth concentration, which should never, however, reach the point of intoxication. This concentration should be maintained over a long period, but care must be taken that the organism does not become oversaturated with the drug. The essential thing is to obtain a regular and uniform absorption. In intravenous injections the absorption is rapid and regular, but clinical experience proves it to be dangerous. Moreover, the bismuth is rapidly eliminated and therefore daily injections are necessary, a factor which makes the treatment rather troublesome. Subcutaneous injections cannot be recommended; they cause greater pain than the intramuscular method and absorption is slow and more irregular. Intramuscular injection thus is the treatment of election. If a certain amount of bismuth is injected into a muscle and is not immediately absorbed, it becomes encapsuled and the rate of absorption decreases, with impairment of the therapeutic effect. X ray photographs of the nates sometimes demonstrate these encapsuled deposits. The most rapidly and regularly absorbed solution of bismuth is the watery solution. Even small doses, however, cause pain and therefore solutions of bismuth compounds in oil have been employed. Injection of these preparations is less painful, but the absorption of the bismuth is rather slow and irregular. He thought that possibly too much stress was laid by manufacturers and physicians on the production of a painless preparation.

Rates of Absorption and Elimination.

Dr. Lomholt discussed the rates of absorption and elimination of the various compounds of bismuth. He said that the slow and irregular absorption of the oily suspensions is least marked with potassium-sodium-bismuth-tartrate, iodoquinate of bismuth, and bismuth salicylate. The tartrate has the drawback of a varying composition and content of bismuth metal, the iodoquinate has a rather low bismuth percentage, and is rather irritant; but the salicylate has no such drawbacks, and in his view is the most suitable for use in an oily suspension. Of the watery solutions, preference should be given to compounds of restricted solubility. The oxychloride is pure and stable, and therefore makes a good preparation. The daily dose of bismuth metal may be fixed at about 0·5 mg. per kilo of body-weight, higher doses being required with remedies of a slow and incomplete absorption. After four or five injections a thin blue line is generally seen along the edge of the gums; this sign is seen with all intensive treatment and is a sign of strong saturation. The injections should be given in the usual place and manner, but the needle should be retracted slightly during the injection to limit the risk of forcing the fluid into a vein or artery. Should the fluid pass into an artery a serious infarct of muscle and skin may ensue.

No treatment of syphilis should be given, he said, as a mere routine; each single case should be considered by itself. Dr. Lomholt concluded his address by showing tables illustrating the absorption, storage, and elimination of bismuth in a number of animal experiments.

The Fate of the Bismuth.

Mr. V. E. **Lloyd** said that it was essential to possess an accurate knowledge of the fate of the bismuth used. It was clear from Dr. Lomholt's address that there was considerable variation in absorption, which was dependent mostly on solubility. Well-defined deposits had been seen by X rays 12 to 15 months after cessation of treatment. He asked whether encapsulation had taken place in these cases, and whether the presence of an unabsorbed focus was a counter-indication to further bismuth therapy. If so, what methods could be adopted to promote absorption? He believed that pain varied with the anatomical site and the bulk of the injection. As to intoxication this might perhaps be avoided by giving a rapidly absorbed solution in the early stages and a more slowly absorbed one later. It seemed from Dr. Lomholt's tables that most of the bismuth was found in the organs of elimination and detoxication—viz., the liver, kidneys, and intestines.

Dr. **Morna Rawlins** asked what constituted the toxic point of bismuth therapy. In her opinion the blue line was always associated with pyorrhœa; she herself had never found it in edentulous adults, and rarely in children. Pain was rarely complained of in women and children, and in her view was due more to faulty technique than to the type of preparation used. She asked whether Dr. Lomholt considered that absorption was diminished when the body was saturated with bismuth.

Dr. **David Lees** asked whether the results of animal experimentation were applicable to human beings. He had yet to see a stomatitis from bismuth in a young child with good teeth or in the edentulous. He also attributed pain largely to faulty technique. Massage was of great value in its elimination. He was not prepared yet to accept bismuth as a substitute for arsenobenzol.

Colonel L. W. **Harrison** said he had had difficulty in reconciling the findings of different investigators; he attributed the discrepancies to the use of different animals for experimentation. The blue line was one sign of toxicity, but more attention should be paid to the kidney. It was desirable to know the maximum dose that could safely be given; the tendency was to give too little. Dr. Lomholt had advised against the deep subcutaneous method, but Colonel Harrison had not found this to be painful with the oxychloride, the metal, or the salicylate in oil. There was less danger of intravascular injections if the deep subcutaneous method was used. It had been observed that with massage bismuth appeared in the blood two to three hours after injection; without massage it did not appear for 24 hours. Massage should produce more regularity in absorption.

Dr. **Tytler Burke** suggested that a false premise had been involved; neither arsenic nor bismuth by themselves were direct spirochæticides. He would like to know what Dr. Lomholt's experience of the use of metallic bismuth had been. He himself believed the blue line to be due to the presence of sepsis. In his experience children tolerated bismuth cream better than mercurial cream.

Reply.

Dr. Lomholt said that it was risky to draw too definite a conclusion from the results of animal experimentation, but mercury experiments with rabbits and with man gave very parallel results. He agreed that faulty technique might cause pain, but there was no doubt that there was a great difference in pain production between the different preparations. In his experience the therapeutic value of colloidal preparations was markedly inferior, although more could be given. Intoxication by bismuth was much rarer than by mercury. Bismuth-treated patients commonly showed the blue line even when they had well-kept mouths; but he agreed that in the absence of oral hygiene the blue line would be found still more frequently. The cause was, of course, the H_2S precipitating the sulphide of bismuth in the gums. It was his definite opinion that, even with perfect hygiene, all people would show the blue line after a course of 10 to 12 injections of an ordinary volume of bismuth. He did not recommend the use of quickly absorbable preparations at first, followed by the more slowly absorbable; he preferred a regular absorptive rate. The amount of bismuth stored in the tissues was only half that of mercury, indicating a more rapid elimination. He would rather make the intervals between the injections shorter, especially as intoxication was less easily reached with bismuth than with mercury. With regard to the correlation of the findings of different experimenters using different animals, he had found that guinea-pigs did not tolerate the injections as well as rabbits; elimination appeared to be constant, however, for all metals with all the animals used. The highest safe dose could not be determined for man from animal experimentation. He was inclined to regard up to 25 mg. per day as a safe dose. It should be remembered that bismuth was given in doses three to four times as big as those of mercury, and often in greater dilution; their relative toxicity could not therefore be fairly contrasted. He had not investigated the deep subcutaneous method with bismuth, and was not aware that it was being used. A Swedish investigator had found that mercury given by this method was painful, and the rate of absorption slower. He had had no personal experience of the use of metallic bismuth; he knew that one form was used in the early days, but had been given up since it caused necrosis. Suspended in oil it was very slowly absorbed. As for percutaneous administration absorption was very very slow.

THE LONDON MEDICAL EXHIBITION.

(*Concluded from p. 940.*)

Surgical Instruments.

Allen and Hanburys, Ltd. (Bethnal Green, London, E.), had an attractive selection of surgical instruments of every description and made a special feature of Statham's Improved Tubal Injection Syringe for injecting lipiodol under control of the X ray screen, with a luminous dial to the pressure gauge, allowing it to be read in the X ray dark room. Attention was also drawn to instruments for the introduction of radium needles and radon seeds and to the St. Bartholomew's Hospital Operation Table with new patent self-locking device for obtaining the Trendelenburg position.—Down Bros., Ltd. (21 and 23, St. Thomas's-street, London, S.E.), presented a large selection of surgical instruments and appliances, prominent among which were Ivan Magill's Portable Intratracheal Apparatus for chloroform, Lane Joynt's skin-grafting instruments for large grafts, and sets of diagnostic instruments fitted with electric light. Putti's orthopædic operation table, for which Down Bros. are the sole agents, also received attention.—Mayer and Phelps, Chiron House (59–61, New Cavendish-street, London, W.). The high standard of surgical instruments made by this firm is well maintained, and among notable instruments to be seen were Rowbotham's Tracheal Intubation Apparatus for use via the mouth or nose, allowing a constant positive pressure and preventing the possibility of aspirating fluids into the lungs, Forceps for the introduction of radium capsules as made for the Radium Institute, and Pepper's Hæmostatic Guillotine for bloodless tonsil enucleation.—Arnold and Sons (Savory and Moore (1928)) (50–52, Wigmore-street, London, W.) made a feature of their improved and inexpensive pedestal operation table on oil pump base, while attention was called to their "Clearlite" forehead lamp and to their anæsthetic apparatus and blood pressure instruments. A notable exhibit was the rubber sponge cushions for use on anæsthetic stools.—The Holborn Surgical Instrument Co., Ltd. (26, Thavies Inn, Holborn Circus, London, E.C.), displayed a large variety of chrome-plated surgical instruments and their Holborn pedestal operation table attracted much attention—mounted on an oil pump it has a chrome-plate top which tilts to any angle and if required the table can, in addition, be fitted with a lateral movement.—Subaqueous Intestinal Bath Apparatus (Agent: F. Rossendale, The Manor Cottage, Gerrards Cross, Bucks). Demonstrations of this apparatus were given, its merit being the ease with which it can be adjusted to the patient, the facility with which the returning liquids and solids are disposed of, and the prevention of obnoxious smell.—Philips Lamps, Ltd. (145, Charing Cross-road, London, W.C.). The Metalix-Portable X ray outfit exhibited by this firm attracted a continuous stream of inquirers, for the apparatus can be erected in a few minutes and after attachment to any convenient light socket radiograms can be taken by simply pressing a button. The two packages in which the complete outfit is contained can be carried wherever required. The apparatus is so insulated that there is no danger from electric shock. A wide range of X ray tubes was also included in this exhibit.—Mr. R. H. Dent (309, Oxford-street, London, W.) showed a wide range of "Ardente" appliances for the deaf suitable for many and varied cases. Some of the appliances are inconspicuous, and all of them give good tonal results.—Bruce and Evelyn, Surgical Corsetières (47, Wigmore-street, London, W.), had an interesting display of corset belts, and belts for all kinds of surgical conditions, special attention being paid to lightness and efficiency.—Domen Belts Co., Ltd. (456, Strand, Charing Cross, London), presented a wide selection of belts, based on physiological and anatomical considerations, for pregnancy, accouchement, and general support, for hypogastric and gastroptosis, for floating kidney, as well as an umbilical hernia belt.—The Scholl Mfg. Co., Ltd. (Granville-square, London, W.C.), showed a wide selection of appliances constructed on anatomical principles for the relief and correction of acquired foot troubles.—Short and Mason, Ltd., "Tycos" (Aneroid Works, Macdonald-road, London, E., and at Atlantic House, Holborn Viaduct) exhibited their well-known sphygmomanometers and clinical thermometers as well as an extremely sensitive recording barometer. All these instruments are of excellent quality.—Bruce, Green and Co., Ltd. (14, 16, 18, Bloomsbury-street, London, E.C.), presented a variety of well-made optical and electrical apparatus, including ophthalmoscopes and retinoscopes, optical trial sets, and sets electrically illuminated for the examination of the ear, nose, and throat.—Kodak, Ltd. (Kingsway, London, W.C.), made an effective display of their clinical cameras, lantern slides, films, intensifying screens, developing tanks, and accessories for X ray dark rooms, and photographic materials for still and moving pictures of medical subjects.

Milk and Foods.

Glaxo Laboratories (56, Osnaburgh-street, London, N.W.). The various forms of dried milk exhibited by this firm included Sunshine Glaxo or humanised milk with added Ostelin, a physiologically standardised concentrate of vitamin D, prepared by irradiation; Standard Glaxo, a full-cream milk; Glaxo Malted Milk; and Glax-Ovo, described as a food drink. Ostelin is available in many forms including colloidal calcium with "Ostelin" Vitamin D ampoules for subcutaneous injection, tablets, and in emulsion with vegetable oil and pure calcium glycerophosphate.—**Libby, McNeill, and Libby, Ltd.** (8, Great Tower-street, London, E.C.). The merits of Libby's evaporated milk were demonstrated at this stall, and extracts from scientific literature were distributed showing that the vitamin content of evaporated milk is as satisfactory as that of raw milk. It was also pointed out that the vitamins A, B, and D were not lost in Libby milk, but that orange-juice or tomato-juice should be given in conjunction with it to supply vitamin C.—**Trufood, Ltd.** (Wrenbury, Cheshire, and Lever House, Blackfriars, London), displayed their various pure milk products, calling special attention to Trufood full cream which can be used from 9 months onwards and for general purposes, pointing out that it is particularly useful to follow breast feeding or Humanised Trufood. Seeway, a pure sweet whey in powder form, also received much attention.—**Cow and Gate, Ltd.** (Guildford, Surrey), attracted attention with their display of Cow and Gate milk prepared by a special roller process under the most scientifically controlled conditions and the claim is made that the milk is adjustable to any infant condition. Prominence was given to Lacidac, which is the dried milk to which lactic acid has been added. This is prepared for use by the addition of hot, boiled water and is recommended in convalescence from acute infections, marasmus, eczema, and in diarrhœa and vomiting.—**Nestlé and Anglo-Swiss Condensed Milk Co.** (6, 8, Eastcheap, London, E.C.), in addition to their full-cream condensed milk, in which the vitamins and milk salts are retained, showed milk food in powder form prepared from full-cream milk, malted wheat products, and tasteless principles of cod-liver oil. Lactogen, made from dried milk with the addition of lactose and approximating to mother's milk, also received marked attention.—**Bovril, Ltd.** (148–160, Old-street, London, E.C.). Bovril, which was effectively displayed both in the form for general use and the unseasoned Invalid Bovril, is too well known to need any description.—**Hovis, Ltd.** (London, Macclesfield, Manchester, and Bristol), had an exhibit showing the superiority of Hovis Bread in regard to vitamin B content, and demonstrated that one slice of their bread weighing 1 oz. contains as much vitamin as 2 oz. of wholemeal and as 5 to 6 g. of fresh yeast.—**Bengers Foods, Ltd.** (Otter Works, Strange ways, Manchester), in addition to their well-known food, displayed Liquor Pancreaticus, Liquor Pepticus, Liquor Thyroididin, Pancreatised Lentil Flour, and other digestive preparations.—**Brand and Co., Ltd.** Mayfair Works, Vauxhall, London, S.W.), presented their preparations which are made under hygienic conditions, and include Essence of Beef and Chicken, Meat Juice, Liquid Peptone, and Ferrocarnis, a pleasantly flavoured solution of iron in organic combination with concentrated meat juice.—**Cadbury Bros., Ltd.** (Bournville), exhibited samples of their well-known chocolate and cocoa.—**Frank Cooper, Ltd.** (Victoria Works, Oxford), had an attractive display of their popular "Oxford" Marmalade, which has a distinct flavour of the Seville orange and is made under strictly hygienic conditions, while every process is done by hand and no preservative or colouring matter is used. In it all the essential properties of the orange are preserved in a high degree. Horsedish Cream, made from freshly grown horse-radish and the best dairy cream without preservatives, as well as an appetising fresh mint jelly, also received much attention.—**H. A. G. Coffee Co., Ltd.** (40, Theobald's-road, London, E.C.), had an interesting exhibit, showing by models and pictures the action of caffein on the human system and of their coffee from which the caffein has been removed. This pure coffee is not affected either in flavour or aroma, as the sample cups offered to visitors demonstrated.—**W. Gaymer and Son, Ltd.** (Attleborough and London), whose exhibit at this exhibition is the first since 1912, are cyder makers to the King, and they specialise in dry cyders for medical requirements. The cyder, which is made from English apples only, is pleasing to the palate and was much appreciated by the many inquirers at the stall.

MISCELLANEOUS.

Kolynos Incorporated (Chenies-street, London, W.C.) showed their well-known preparations, including dental cream which is antiseptic and does not in any way injure the enamel of the teeth; liquid Kolynos, which can be used as a mouth-wash, gargle, or spray; a denture powder, a new preparation for thoroughly cleansing artificial teeth and dental plates; as well as a delicately scented skin soap.—**J. C. Eno, Ltd.** (Fruit Salt Works, Pomeroy-street, London, S.E.), displayed their useful saline laxative; and **The Thermogene Co., Ltd.** (160, Piccadilly, London, W.), the scientifically prepared cotton-wool sold under the trade name, which stimulates the circulation in the affected part of the body to which it is applied and relieves congestion and inflammation.—**United Water Softeners, Ltd.** (Aldwych House, London, W.C.), demonstrated their "Permutit" household water softeners which do not impair the palatability of the water. Plants suitable for softening water on a larger scale were also shown.—**Keen, Robinson and Co.** (Carrow Works, Norwich), among other exhibits, showed Almata, described as a food for infants, a galactagogue, and a supplementary diet for invalids: and Keen's Mustard Ointment.—**The Medical Sickness, Annuity, and Life Assurance Society, Ltd.** (330, High Holborn, W.C.). This mutual Society of medical and dental practitioners, which was founded in 1884 for the purpose of enabling doctors and dentists to obtain sickness, accident, and life insurance on more advantageous terms than those offered by proprietary companies, was well represented, and members of the staff were constantly in attendance to demonstrate the advantages of insuring with a professional society.—**The Medical Agency** (William H. Grant, Watergate House, 15, York-buildings, Adelphi, London), which undertakes all forms of medical accountancy and obtains capital for medical practices through banking channels, in addition to negotiating for medical and dental practices, and effecting all forms of insurance, demonstrated to medical men the services offered by the firm.

SPAS AND MEDICINAL WATERS.

In addition to the interesting displays of photographs and literature by the English spas of Bath, Buxton, Harrogate, and Torquay, **Ingram and Royle, Ltd.** (Bangor Wharf, 45, Belvedere-road, London, S.E.), made an imposing show of mineral waters, salts, and pastilles, including Carlsbad Water, Hunjadi János, Vichy-Célestins, and Contrèxeville-Pavillon.

MEDICAL AND SCIENTIFIC PUBLISHERS.

Baillière, Tindall and Cox (7 and 8, Henrietta-street, London, W.C.) exhibited a large number of books published by their own and other firms, and **William Heinemann, Ltd.** (99, Great Russell-street, London), also showed a large number of the latest medical and surgical works, while **H. K. Lewis and Co., Ltd.** (136 and 140, Gower-street, and at Gower-place, London, W.C.), in addition to medical books published by the firm, called attention to their medical and scientific library. Notable exhibits at this stall, which provoked many inquiries, were the Register Doctors' Cabinet for holding index system cards and the Roll-Top Cabinet made specially to hold panel cards and envelopes issued by the Ministry of Health. These cabinets are soundly constructed in oak and are very convenient fitments for the surgery.

Reviews and Notices of Books.

ENDOCRINE DISORDERS.

By Prof. HANS CURSCHMANN, M.D., D.Ph., Director of the Medical Clinic, University of Bostock. London: Humphrey Milford, Oxford University Press. 1929. Pp. 168. 12*s.* 6*d.*

"Endocrine Disorders," by Prof. Hans Curschmann, has recently been added to the series of Oxford Medical Publications, and is a thoroughly clinical and practical monograph. Endocrinology has advanced so rapidly during the last 50 years that the standard text-books of medicine have scarcely succeeded in keeping pace with it. The sections devoted to endocrine subjects are meagre compared with those which bear such established headings as circulatory or alimentary disorders. On the other hand, the special monographs on endocrinology tend to supply the practitioner with a mass of anatomical, physiological, and experimental data which he does not require. This book is compact, and gives a clear account of the various glandular syndromes in under 200 pages. The author has drawn largely from the *work of the mid-European authorities and from* his own wide personal experience. The chapters on disorders of the thyroid and parathyroid deserve special praise. The author discusses the various forms of Graves's disease, pointing out that the metabolic, circulatory, and other symptoms of these syndromes are essentially the same, and that there is a ready transition between the different types. The factors concerned in hypoparathyroidism, tetany, calcium deficiency, and spasmophilia are clearly defined. In the chapter on pituitary disorders there are one or two notable omissions. No reference is made to the suprapituitary craniopharyngeal pouch cysts and their symptoms, or to the syndrome associated with the chromophobe adenomata. On the other hand, the accounts of acromegaly and of diabetes insipidus are admirable. This chapter also includes an interesting general discussion on the ætiology of endogenous obesity and emaciation. Dr. F. Prange coöperates in the chapter on gonad dysfunctions. In the remaining chapters *the arrangement* of the subject matter, in itself very complete, is not wholly satisfactory. One finds, for instance, scant mention of the sex disturbances associated with tumours of the adrenal cortex in the adrenal chapter, but a good account in that dealing with the pineal gland. Here also a considerable amount of space is devoted to a discussion of the various types of infantilism, though there is, of course, no suggestion in the text that the pineal is an ætiological factor in any of them. As a supplement to the standard text-books of medicine the monograph can be recommended both to students and practitioners.

DISEASES OF THE MOUTH.

Third edition. By STERLING V. MEAD, D.D.S., Professor of Oral Surgery and Diseases of the Mouth, Georgetown Dental School. London: Henry Kimpton. With 330 illustrations and 43 colour plates. Pp. 727. 42*s.*

NOT many years ago a volume of over 700 pages *would have been considered a liberal allowance for* an account of the whole of dentistry. But the last few years have seen the appearance of many large volumes devoted to various aspects of odontology. We are constrained to admire the industry of the writers, chiefly trans-Atlantic, who produce these massive tomes, the enterprise of the dentists who purchase them, and the advances of such a comparative young and limited branch of medicine which have produced such an extensive literature. There remains some doubt, however, whether so vast a literature is really justified by the growth of our knowledge, and whether books on dentistry could not be made more concise without detriment.

The fact that three editions of this work have been called for in less than a year is a tribute to its worth which is on the whole merited. It represents an attempt to include in one work all the diseases of the mouth, both those connected with the teeth and those arising from other sources. Such strictly dental conditions as periodontal infections, diseases of the dental pulp, malformations of the teeth, malocclusion, and impacted teeth are dealt with, and in addition there are accounts of tumours innocent and malignant, of specific infectious diseases such as syphilis and tubercle, diseases of the blood system as they may affect the mouth, diseases of the mucous membranes, and so forth. Its appeal is thus to dentist and to doctor. The convenience of a book which covers the whole range of stomatology cannot be denied. The strictly dental section is sometimes disappointing, as if the author had included it only for the sake of completeness and without conviction that it would be helpful. The five pages devoted to diseases of the dental pulp are inadequate, and so are the three or four on malocclusion. On the other hand, the accounts of the various disorders of the mucous membrane are excellent and give the dental reader a good idea of common conditions which his hospital training tends to leave out of account. The chapters on tumours are also good, though the account of the odontomas ignores much valuable work done in this country. In the description of salivary calculus there is no mention of the work of A. Bulleid on the rôle of the leptothrix in its formation.

There are inaccuracies and omissions, and in some ways this voluminous work seems to give a curiously scrappy effect. But on the whole it is a very sound and informing book. The bibliographies are full and international, while the illustrations, especially the coloured plates, are excellent. Its rapid popularity is not surprising.

PREVENTION OF HUMAN TUBERCULOSIS OF BOVINE ORIGIN.

By WILLIAM G. SAVAGE, B.Sc., M.D. Lond., D.P.H., County Medical Officer of Health, Somerset. London: Macmillan and Co., Ltd. 1929. Pp. 195. 10*s.* 6*d.*

Dr. Savage calculates that the number of deaths due to tuberculosis of bovine origin in this country was, in 1927, 1945. The table from which this figure is quoted was prepared on the assumption that 1 per cent. of the respiratory and 23 per cent. of the non-respiratory tuberculosis in each year is of bovine origin. The total deaths calculated on this basis have fallen from 3382 in 1918 to the figure quoted above. Dr. Savage admits that the method employed for determining these figures may be open to question, but it would be difficult to devise a more satisfactory method of arriving at statistics without a very elaborate bacteriological investigation of fatal cases. The number of cases of bovine origin which recover cannot be ascertained, since the notification statistics are not informative on this point.

On the prevalence of tuberculosis in cattle the author gives various methods of arriving at reliable data. Unfortunately, none of these methods is free from difficulties, but the various figures quoted from numbers of counties and county boroughs show that the percentage of tubercle-positive milk samples *examined varies from 0 to 13·2 per cent.* Dr. Savage also examines, with great care, the various methods which have been suggested, and those which are in actual use for the prevention of bovine tuberculosis. A detailed investigation of these points occupies the greater part of the second half of the book. The author deprecates attempts to tackle the reduction of bovine tuberculosis in a piecemeal fashion. If anything of value is to be done a large and comprehensive scheme must be evolved, including all sides of the question, bacteriological, veterinary, and agricultural. The production of an artificial immunity against the tubercle bacillus and the rearing of resistant herds are methods still in the experimental stage. Dr. Savage discusses Prof. Calmette's work with B C G in detail, and leaves us with the impression that he is not hopeful of its ultimate prospects. He also deals at length with the theory held in some quarters that the bovine tubercle bacillus is of lower virulence than the human: he finds that the evidence to substantiate the theory is inadequate. On the question of the immunising value of tuberculous milk Dr. Savage is quite definite—it is, he says, "a procedure so unwarranted that I feel its advocates cannot have realised its full implications."

Every public health worker and every bacteriologist specially concerned with the tuberculosis problem will be glad to keep this book upon his shelves as a large source of unbiased information. In his preface the author states that the literature of his subject reveals neither unanimity on the remedies nor agreement on the facts. He himself has gone far towards clearing the ground.

THE NERVOUS CHILD.

Fourth edition. By H. C. CAMERON, M.D., F.R.C.P., Physician in Charge of the Children's Department, Guy's Hospital. London: Humphrey Milford, Oxford University Press. 1929. Pp. 240. *7s. 6d.*

THE greater part of this popular book is unaltered, but it has been enriched by a new chapter on the underlying disturbances of metabolism in the nervous child. Here Dr. Cameron has set out in a lucid and persuasive manner the views to which he has from time to time given expression on the relation of ketogenesis to the various manifestations of neurosis in childhood. The sudden disturbances of health to which certain children are liable, varying in their form but typified by cyclic vomiting, are associated with a failure to mobilise sufficient carbohydrate to achieve the complete metabolism of the fat which has been absorbed. It is here suggested that this metabolic disturbance may be dependent on a temporary functional impairment of the suprarenal glands, the acidosis itself producing secondary results such as catarrh of mucous surfaces and attacks of bronchial asthma. Dr. Cameron does not pursue further the ætiology of the suprarenal insufficiency, but he implies that a diet too rich in fat may be a contributory factor; he stresses the fact that the symptoms are seen more often among the children of the well-to-do than in hospital practice. The principal lines on which these disorders may be combated are an adjustment of the diet (for which full details are given) and the administration of alkali and of glucose. This chapter adds considerably to the interest of the book; it also, however, introduces into it material which is somewhat more contentious than the original chapters. It will appeal to the reader as a brilliant exposition of one view of a question on which unanimity has not yet been reached.

USE OF SYMPTOMS IN DIAGNOSIS OF DISEASE.

Ninth edition, thoroughly revised. By HOBART AMORY HARE, B.Sc., M.D., LL.D., Professor of Therapeutics and Diagnosis in the Jefferson Medical College of Philadelphia. London: Henry Kimpton. Pp. 528. 30*s.*

IN the present preface to this familiar book Prof. Hare quotes Dr. Maitland Ramsay's words: "At the present day the purely clinical side of medicine is spoken with a certain condescension and is apt to be undervalued. . . . There is too little study of what used to be called the face and mind of disease." This book has been designed according to the plan which is actually followed in practice—namely, to build up a diagnosis by grouping the symptoms. For instance, instead of describing locomotor ataxia, the author provides a section on the various forms of loss of power in the legs in which ample data for differential diagnosis between various nervous diseases will be found. Similarly, the short but excellent chapter on coma covers a great variety of diseases, all producing this important symptom.

The plan adopted implies, consequently, the power of the author to pass on to his reader his experience of symptoms in practice in such a way that they may be readily assimilated and correlated with the general experience of medical men. The chapter headings give a key to the arrangement of the work. The face includes expression, colour, deformity, paralysis, and spasm; the skin—its colour, eruptions, scars, moisture, dryness, anæsthesia, hyperæsthesia, and paræsthesia; and the tongue (to take a third example), general appearance, coating, fissures, ulcers, eruptions, atrophy, hypertrophy, paralysis, tremor, and spasm. There are excellent chapters on abdominal disease, on the nature of the fæces, on vomiting, and on the thorax and its viscera, each built up on the symptomatic plan. The chapter on the eye deserves special mention on account of its admirable illustrations and its explanation of the art of diagnosis in plentiful supply throughout the whole volume.

This book has been and will be widely read by all and especially by those who have felt that in recent years the scientific aspect has unduly overshadowed the art of medicine.

JOURNALS.

LIVERPOOL MEDICO-CHIRURGICAL JOURNAL.—Efforts to restart this journal, the organ of the Liverpool Medical Institution, which ceased to appear during the late war, have been successful, and the thirty-seventh volume appears this month. It contains a number of interesting papers, the first of which is the inaugural address on Harvey delivered by Prof. John Hay, at the opening of the ninetieth session of the Institution. Dr. C. O. Stallybrass, assistant medical officer of health, writes on acquired immunity in human populations, Mr. Watson Jones on the treatment of fractures by intramedullary pegging, and Mr. Howel Evans on some hæmorrhagic conditions. Dr. I. Harris publishes an article on the diagnosis of chronic myocarditis by means of the electrocardiograph, and Dr. M. Datnow discusses the effect of lead on the tissues. Dr. Stuart McAusland advocates the treatment of varicose veins by injection, and Dr. Alston Hughes discourses on "Vision and Vocation." The journal includes the transactions of the Institution and reviews. As the foreword observes, a scientific society without transactions is as imperfect as a man without a shadow, and we congratulate the journal on its renaissance.

DISEASES OF THE PITUITARY BODY.—Dr. O. Leyton writes that our reporter misunderstood his words at the meeting of the Royal Society of Medicine on Oct. 22nd (THE LANCET, Oct. 26th, p. 877). "I described," he says, "some observations which I had made years ago showing that the antidiuretic potency of an extract of pituitary gland did not depend upon its oxytocic content and then said these observations were confirmed by the separation of vasopressin and oxytocin. I did not claim that my observations had anything to do with the separation of these two bodies. I then went on to give evidence which I thought tended to prove that, although vasopressin controlled diuresis, nevertheless it was not the actual antidiuretic body. Of this I had not absolute proof because the observations were too few and a vital factor was the accuracy with which the vasopressin content in a solution was estimated."

ROYAL VICTORIA HOSPITAL, BELFAST.—Dr. J. E. MacIlwaine has resigned from his position of physician to the hospital; he has been elected a consulting physician with special charge of the electrocardiographic department. Dr. S. B. B. Campbell has been promoted to the rank of physician, and Dr. J. T. Lewis elected to the post of assistant physician thus rendered vacant.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 9, 1929.

TANNIC ACID AND SECONDARY SHOCK.

HOSPITAL registers show for the last 25 years a striking reduction not only in the number of cases of burns admitted, but in the extent of the lesions, the mortality, and the ratio of children to adults. At the London Hospital, for example, admissions of burns in children under 12 have fallen from 150 in 1904 to 38 in 1928 and the mortality percentage from 26·5 to 6·3. The decrease has been steady. Improved living conditions, the substitution of electricity for oil lamps and gas as a source of light, factory and workshop regulations, and the Children Act of 1908 have all contributed to the change. This Act, which makes it an offence to leave a child alone in a room with an open fire, has been effective beyond its immediate application by drawing the attention of parents to the gross dangers of burning and scalding accidents.

Most deaths from burns occur in the period of secondary shock. This manifests itself at a varied interval after the accident, usually on the second or third day, and is marked by the clinical picture of an acute toxæmia. The symptoms are now generally attributed to the absorption of toxins from damaged tissues; the toxins have not been isolated but are probably derived from lysis of the skin proteins. Excision of the whole damaged area therefore should have had, and has had, excellent results, but its limitations are obvious. Dr. E. C. DAVIDSON, of Detroit, therefore sought a means of fixing the toxins before their absorption. In 1925 he published a method of treating burned areas with an aqueous solution of tannic acid, thereby producing a dry brown scab which seems to imprison the toxins. Underneath the scab the reparative processes proceed naturally. Many of those in charge of hospital clinics in this country have adopted this method of treatment with enthusiasm, others have given it but lukewarm praise, while some have not tried it. In view of the important practical and theoretical considerations involved, the Medical Research Council invited Mr. W. C. WILSON, who is working in the department of surgery of the University of Edinburgh under Prof. D. P. D. WILKIE, to put together and publish the results of this mode of treatment obtained at the Royal Hospital for Sick Children, Edinburgh. His report was summarised in THE LANCET last week, and in our present issue we set out instructions for first-aid treatment by tannic acid. Mr. WILSON confirms the high claims made by Dr. DAVIDSON. His assurance that the mortality in hospital cases of children under 10 years has been reduced from 38·7 to 10·5 per cent. must be assessed in relation to the lowered mortality following burns in other hospitals; far more convincing is the statement that deaths during the period of secondary shock or acute toxæmia have fallen from 80 to 23 per cent. and that the area of skin involved, on which prognosis has usually been based, can be larger without danger to life if this treatment is followed. The involvement of 30 per cent. of the total body surface in adults, and of 11 or 12 per cent. in children under 10, has been regarded as almost certain to prove fatal. In Mr. WILSON'S series, 35 children were burnt to the extent of 12 per cent. or more of the body surface, and of these 27 recovered. These figures furnish strong evidence of the efficacy of tannic acid, and if we add the alleviation of pain and the escape from frequent dressings which the method provides we are surely in a position to welcome a notable advance in therapeutics. It would be interesting to have figures from other institutions in this country; the Edinburgh mortality figures appear to us exceptionally high. Hospitals in cities where the number of severe burns admitted is comparatively small may not yet have been stimulated to try the method. It is essential to remember that unless the technique is studied and applied in detail, the method is not likely to give the best results. All loose epithelium must be separated and the surface carefully cleaned, for the problem of sepsis, should it arise, is certainly not diminished by the tanned pellicle. Fomentations and other moist applications may not be used over the scab since they seem to liberate the toxins.

Although most suited for use in hospitals since it entails anæsthesia, thorough cleaning, hourly spraying till the tan forms, drying appliances, and protective cradles, this treatment may also have a wide scope where circumstances do not favour such a complicated technique. The provisional scheme of first-aid treatment drawn up by Mr. WILSON for use in mines and other places where burning injuries are not uncommon involves the use of compresses soaked in the tannic acid solution. The drawback may be sepsis, for it is noteworthy that in Mr. WILSON'S experience the deaths from this cause are not noticeably diminished. It is thus of prime importance that better prevention and control of infection should be attained and investigations in this direction are being pursued. There is no suggestion that tannic acid is an emergency measure of choice which should be kept in the home and used for the routine treatment of all burns. In fact, as Dr. D. A. COLES points out in our correspondence columns, for the present it is best used only under medical supervision. Small superficial burns of the first degree are likely to heal quicker when treated with some simple dressing than when exposed to the astringent action of tannic acid, while those of the second degree are no less likely to become septic. A safe rule at present is to attempt this treatment when the burn is severe enough for secondary shock to be anticipated, for there is ample evidence that the shock will be considerably diminished by its use.

◆

THE LAW OF WATER-SUPPLY.

THE Advisory Committee on Water has just published[1] the Second Report of its Legislative Sub-committee. The First Report dealt with the law of underground water; the Second Report proposes detailed reform of the law of water-supply. More than 80 years ago Mr. BOOTH, Counsel to the Speaker, framed a series of Clauses Consolidation Acts, dealing with railways, companies, land acquisition, gasworks, and so on, which collected the sections most frequently recurring in local Acts, and thus, by making available a code for incorporation in the special Act governing an individual undertaking, brought great advantages of brevity and uniformity to local legislation. One Act of this series was the Waterworks Clauses Act of

---

[1] H.M. Stationery Office. Pp. 82. 9d.

1847, a general code which, though amended in 1863, hardly satisfies the needs of to-day. In inquiring into existing legislation the Subcommittee has closely examined this Act of 1847 and also the successive provisions of the Public Health Acts, the Model Bills and Clauses of the House of Lords, and the precedents introduced into local Acts on the initiative of progressive bodies. Everywhere the Subcommittee finds different powers and different procedure; it considers that the time has come for a fresh consolidation of the law, a new Waterworks Clauses Act for uniform incorporation by undertakers, and a general amending and equalising statute which will advance the position all along the line.

It was hardly to be expected that a code fashioned 80 years ago should keep pace with the growth of greater efficiency in water-supply and the extended requirements of modern sanitation. Thus among other anachronisms is the notion that baths and water-closets are exceptional luxuries outside the normal range of "domestic supplies" and justifying additional water charges. Parliament nowadays stipulates for the condition that no extra payment be demanded in respect of the first water-closet in a house. The Report proposes a definition of domestic supplies which will cover supplies for water-closets and for "baths of capacity not exceeding the prescribed number of gallons." Though the Subcommittee has drafted a permissive clause enabling the supply of water by meter for domestic purposes if the consumer so prefers, it does not recommend the compulsory metering of domestic supplies. Economy in the use of water may be an enemy of public health. Waste naturally affects finance. Gas companies (as CLIFFORD observed in his "History of Private Bill Legislation") have made better profits than water undertakings, although they sell an article which usually costs more to produce. But gas companies have the benefit of a metering system which checks waste and—charges not being based on rateable value—causes rich and poor alike to pay for what they consume. Metering might promote economy of water consumption in areas where shortage is possible, but there are other ways of preventing waste. Thus the Subcommittee advocates fuller provisions for penalising waste, misuse, or contamination of water, better powers of making and enforcing by-laws, closer attention to maintenance and repair of fittings, and the fixing of meters on service pipes and mains and stop-cocks on supply pipes. This last suggestion not only helps the detection of waste and the cutting off of supply where water is misused; it also avoids unnecessary disturbance of the roadway surface now so elaborately constructed and so heavily used by traffic. Another recommendation is that supply pipes under highways, connecting water mains with private premises, should no longer belong to private owners but should be handed over to the water undertaking with the liability for upkeep at the latter's expense. Further proposed reforms affect finance—e.g., the relation of reserve and contingency funds; some such revision of the law was carried out for gas undertakings last May. There is mention, too, of superannuation arrangements, the power to furnish or purchase bulk supplies and the need of ensuring proper construction of reservoirs. This last point, which recalls the Dolgarrog disaster of 1925, seems to be dealt with by the Government's new Reservoirs (Safety Provisions) Bill. It is recommended also that Section 70 of the Public Health Act of 1875 should be extended; at present the local authority can ask a court to order the closing of a well, tank, or cistern if the water is likely to be used for human consumption and is so polluted as to be injurious to health; it is advocated that the local authority be enabled to act without waiting for actual pollution to occur.

Other proposed reforms appear equally sound and deserving of support. One difficulty ahead is the devising of machinery whereby the new uniformity may be substituted for the old variety in the multitude of enactments governing individual undertakings. Undertakers will naturally be reluctant to incur the expense of a new local Act to bring each concern's position into line. Not anticipating serious opposition to the necessary changes, the Subcommittee advocates giving the Minister of Health power to alter the law in particular cases by departmental order. There are ample precedents for such a method, but the vigilance of Lord HEWART may hinder their extension.

◆

THE LIFE OF FOOD.

SCIENTIFIC inquiry is a species of human activity which may be initiated by a variety of motives. Its pursuit is found to be peculiarly satisfying to the increasing numbers of men who devote their main energies to it, and for such men the very fact that they are endeavouring to increase the sum total of human knowledge may be a sufficient reward for their labours. Other less detached individuals may be no less anxious to inquire into the truth concerning the mechanism of natural phenomena, but prefer, or are compelled by circumstances, to select for solution problems which have a more or less direct bearing on the every-day life of the community. There is no essential distinction between these two classes of investigators. The fundamental principles enunciated by the former are frequently applied to practical inventions which may influence profoundly the life of humanity at large, while the attempts to solve some practical question affecting the ordinary life of man may often lead to the discovery of basic principles which are primarily of academic value.

A good illustration of this thesis is to be found in the annual review of the work of the Food Investigation Board.[1] The work is avowedly utilitarian, and is concerned essentially with devising means of storing and transporting food, so that it shall reach the consumer in the best possible condition with the minimum risk of wastage. The practical results already obtained are of very considerable economic importance, but, in addition, conclusions have been reached in certain directions which may prove of considerable significance in the realms of pure animal and plant physiology. Among the subjects of current investigation are the changes undergone by meat during freezing, cold storage, and thawing; important practical recommendations have already followed the work accomplished in this field. In the course of this work it has been found that there is a zone of low temperature within which lactic acid can still be produced, although the machinery for its destruction has been destroyed, an observation which may have an important bearing on the physiology of muscle contraction. The current methods of handling fish on trawling vessels have been the subject of special inquiries, and it has been found that without increasing the running costs of the vessels it is possible to extend the time during which fish can be landed in a fresh condition from 6–7 up to 10–11 days. Most interesting, perhaps, are the observations on the storage of fruit. Not many years have passed since the purchase of fruit in this country during the winter and spring months was almost impossible. Now there is a plentiful supply of apples, oranges, and tomatoes, not to mention other varieties, all the year round. The prices are often high, it is true, but this is in part owing to wastage occurring during storing and handling. It has been one of the tasks of the Board to investigate the causes of this wastage, an inquiry which has involved a study of the fundamental biological processes that occur in fruit during the various stages of its career. The conception of an apple (for instance) as a living structure that is continually respiring and producing measurable quantities of heat has been borne in mind; it has been shown that the apple, after passing through the phase of immaturity, reaches a period which has been called the climacteric, during which there is a marked increase in the rate of respiration, and an alteration in the respiratory quotient which are apparently associated with the production of those chemical substances which confer upon the fruit its characteristic flavour and aroma. This period is followed sooner or later by senescence, which must terminate the useful life of the apple as far as consumption by man is concerned. It is obviously desirable that the factors which control the time of appearance of the climacteric and the subsequent length of the useful life of the fruit should be determined, and with this end in view a large amount of work has been carried out on the influence of the state of maturity at the time of picking, and the temperature, humidity, and composition of the surrounding atmosphere during storage.

---

[1] Report of the Food Investigation Board for the Year 1928. London: H.M. Stationery Office. 1929. 3s. 6d. Copies may be obtained in America from the British Library of Information, French Buildings, 5, East Forty-fifth-street, New York.

This work has not yet been completed, and is being carried on side by side with other important investigations concerning the influence of various types of fungal invasion on the metabolic processes of the apple. It is clear that results of vital importance have already been obtained by such investigation, and we may confidently look forward to a time in the near future when our supplies of food will be improved in regard both to quality and variety, and one may well hope, lowered in price, as the result of the activities of the Food Investigation Board.

THE NOBEL PRIZEMEN.

EVERYONE will be glad that a Nobel prize—at any rate, half of one—has been awarded to Prof. Sir **FREDERICK GOWLAND HOPKINS**, if only because it gives us an opportunity of expressing our affectionate admiration of what he has done, and what he has been, and is, in English biochemistry. His laboratory career has been spattered with the results of his peculiar flair for seeing where the explanations of things lie; the pigments of white butterflies and a method of estimating uric acid are in the early years, the efficacy of milk as a food and glutathione (very frankly qualified the other day) are more mature products. And in between he has been the activating inspiration of a great number of young people. Their experience we envy, and it is not surprising that they flock so abundantly to the "Museum Hoppianum" in Tennis Court-road in Cambridge. **HOPKINS** did not, of course, "discover" vitamins; it is very doubtful, indeed, whether anyone really "discovers" anything in the ordinary sense; they put links into a chain. But the link which **HOPKINS** put into the process of finding out about the fat-soluble vitamins was important, and it came just at the right time, and it is, we suppose, with this particular activity of his in mind that the Nobel electors have joined with him Prof. **CHRISTIAAN EIJKMAN** of Utrecht who, a quarter of a century ago, made quite clear the connexion of beri-beri with diet through his convincing experiments with whole and decorticated rice in relation to the polyneuritis of birds. **EIJKMAN**, too, has not been a man of one idea. He has had a long career of fruitful activity in bacteriology, has devised good practical methods of growing the colon bacillus, and has involved himself in the philosophy of the theory of disinfection. Though "vitamins" is the obvious word which occurs to one's mind on reading the announcement in the papers, it is well to reflect how the many-sidedness of both men has given substance and comprehensiveness to their specialised investigations. And perhaps some of those who work at vitamins now would make better progress if they were not so exclusive in their interests.

Annotations.

"Ne quid nimis."

PARTNERSHIP IN INDUSTRIAL HEALTH.

A BRIEF account appears in another column of a social meeting in connexion with the Industrial Health Education Society. At the luncheon given by Lord Melchett to a representative group of persons directly or indirectly interested in the objects of the Society the need for explaining in detail what had been done and what was being done did not arise because so many in the room were familiar with what might have been said. But it is probable that such knowledge is not at all general or shared by many of the medical profession, who may not know what is the actual work of the Industrial Health Education Society. This Society, first, is the only voluntary society concerned with occupational disease, and its work is directed towards securing one great object—namely, the information of industrial workers as to the diseases and disabilities to which they in their particular trade are liable, so that, at any rate during working hours, certain perils may be avoided. The instruction is given in the form of health talks by medical men and dental surgeons, and on the invitation of the workers themselves—that is to say, the subjects of the health talks are chosen by the workers and the occasions for them are determined by the workers, the meetings being organised in their own clubs and canteens. In this way the presence is secured of workers who certainly would not usually assist at lectures on health where general questions of hygiene, environment, nutrition, and welfare were to be discussed. Yet these are the men who are deeply interested in a practical way in the incidence of occupational disease and accidents, and through the medium of the Society they are asking for instruction along definite lines, and they obtain it as much from the results of the cross-examination to which they are urged to submit the lecturer as from any set delivery of his. The fact that the initiative comes from the workers is of great importance, for the knowledge that the employers are not at the back of the lecturer removes a suspicion which has had malign influence in the United States, where the scientific management associated with the name of Frederick W. Taylor came to be regarded as a new form of oppression under the eponym of "Taylorism." The statistics which have appeared in the United States from many quarters, illustrating the increased efficiency of operatives who are maintained during their work in good health, have been collated with equally interesting figures as to the increased output from factories where sanitary environment is provided. The result has been that the cynical feeling has often been expressed across the Atlantic that the interest shown by employers in the hygienic conditions of the workshop may have its in a commercial intent to get more work out of the men. This is an avenue of distrust which the words used at Lord Melchett's luncheon by the host, by Sir William Milligan, and by Mr. Ben Tillett should close. While the physical suffering is borne by the workers, they share also in the evils associated with trade depressions. The education in the factors of physical amelioration will enable the workers to demand from the employers conditions valuable to both parties, while the employers will have to obtain the knowledge which is being placed at the disposal of the employed, so that they may deal fairly with such demands. Put briefly, the health of the industrial workers is not a matter for parties at all, but for partners.

CEREBRAL INFECTION FROM THE NASAL CAVITIES.

In 1926 the Minister of Health appointed a committee to inquire into the improvements possible in the process of vaccination. The committee, having examined the evidence, reported that in their opinion some light might be thrown on the nature and origin of the nervous complications by a knowledge of the channels by which infection might pass from the nasal cavities to the brain. Prof. le Gros Clark was therefore asked to investigate this problem, and the results of his work have now been published[1] in a pamphlet. Reviewing previous experiments, he points out that the injection of coloured dyes into dead subjects may easily lead to fallacious results, but a connexion between the subarachnoid space and the nasal cavity along the perineural spaces of the olfactory nerve has been repeatedly established. After experimenting with carbon suspension and trypan-blue, he came to the conclusion that the best material was a solution of potassium ferrocyanide and iron ammonium citrate in equal parts, made up to a strength of 1 per cent. This solution is practically isotonic with the body fluids. It was dropped, by Dr. Mervyn Gordon's technique, into the nasal cavity of rabbits and after the death of the animal the tissues were placed in 10 per cent. formalin, with 5 per cent. hydrochloric acid to precipitate granules of Prussian blue. These granules are not diffusible in the preserved tissues after death. When the mucous membrane of the nasal septum was dehydrated, cleared in xylol-phenol or oil of wintergreen and mounted in balsam, the olfactory nerve bundles were found to be strikingly outlined by a deposit of granules along the nerve-sheaths, strewn around in the intercellular spaces of the perineural sheath. Occasionally a few granules were seen in the substance of the bundles among the nerve-fibres, and often the individual sheaths were linked up by intercommunicating strands of blue granules running in among the follicles of the serous glands and forming a sort of plexus. The granules seemed to lie in the connective tissue spaces rather than in endothelial tubes, while the plexus connected up here and there with larger vessels in which the endothelial lining was distinctly visible. Few granules were found in the submucosa of the respiratory part of the mucous membrane, although a deposit of blue might be found on the surface. The sections provided abundant evidence that the solution had been absorbed into the submucous tissues through the olfactory mucous membrane and that absorption could occur within one hour of dropping the solution up the nose.

The granules showed a marked tendency to infiltrate the periosteum and perichondrium covering the turbinate system, and in the region of the cribriform plate there was convincing proof that they entered the cranial cavity. The subarachnoid space becomes continuous through the cribriform openings with the delicate trabecular sheaths of the olfactory nerves, and it was principally along this path—though also partly along the small blood-vessels and by extension along the periosteum—that granules made their way into the skull. The great absorptive property of the olfactory mucous membrane (contrasted with the poor permeability of the respiratory portion which absorbed very small amounts) is probably connected with the sense of smell. From the disposition of the granules it was reasonable to postulate a continuous stream of absorbed fluid passing centripetally along the nerve-fibres from the epithelium to the brain; a current must normally run in this direction. The absorbed solution is partly drained away by the ordinary lymphatic channels, but no evidence was obtained of a communication between the perineural sheath spaces and the lymphatics, or between the subarachnoid space and the nasal lymphatics. There was abundant evidence that the solution was absorbed into the blood capillaries and in a few cases conveyed by minute vessels through the cribriform plate; these vessels theoretically provide a route for pyogenic and thrombotic infections but cannot otherwise play a very important part in disease. Material can also pass to a certain extent into the cranial cavity, though not, of course, into the subarachnoid space, by penetrating the periosteum or perichondrium or passing through the bone of the ethmoid. Infection might thus spread to the extradural spaces. Goodpasture has suggested that the herpetic virus may reach the central nervous system via the axis cylinders of the olfactory nerves. This would depend probably on a peculiar affinity between a specific virus and the physico-chemical nature of the neurone, and was not considered susceptible to anatomical investigation.

While these experiments relate to rabbits, there is one case on record which suggests their applicability to human beings. A man suffering from epistaxis had his nose plugged with a tampon soaked in perchloride of iron. He died a few days later from meningitis, and at autopsy his olfactory bulbs were found to contain iron. The investigations provide an unimpeachable anatomical basis for the theory that certain droplet infections reaching the body through the nasal cavities can obtain direct and rapid access to the subarachnoid space. The brain has usually been regarded as a closed system, marvellously protected from the outer world. The news that fine granules can reach it, by a direct route, within an hour of their impact on the outside of the body offers a wide field for speculation.

HEALTH OF THE R.A.F.

In his latest report[1] on the Health of the Royal Air Force, Air Vice-Marshal David Munro, the Director of Medical Services, is able to give a satisfactory account of the year 1928, and says that 88 per cent. of the officers called upon to fly were found fit for all flying duties. The average strength of the Force was 30,470 men and the admissions to hospital or sick quarters fell to 430·1 per 1000 (467·8 last year) with a considerable reduction in those for "sandfly, malaria, and influenza." Flying units have relatively fewer cases of disease, but of course, far more injuries than the others. Deaths from disease numbered 40 including 5 each from tubercle and enteric. As a result of injury there were 97, of which 65 (an increase of 13) were by flying casualties on duty. The relation of such casualties to the total hours flown is not mentioned this year. The chief causes of invaliding were psychoneurosis (28) and tubercle (22). A joint committee of the three Services has studied the incidence of tubercle, and a new table appears, showing that in the R.A.F. there was a relatively high incidence of tubercle before 25 and after 45 years of age, and between five and nine years' service. The prevalence of venereal disease slightly increased at home. Diphtheria cases were fewer; it is not stated whether this has any relation to the testing and immunisation of last year. Two kinds of influenza vaccine were tried among a total of 960 men; in both groups a third were later attacked by influenza, while in a control group of 1041 men the incidence was much the same. Dysentery on all stations abroad is mostly bacillary. Malaria has been reduced by a half during the year and for this reduction mosquito-proofing of barracks is given most thanks though Paris green is also mentioned. An interesting account is given of the difficulties of a force on active service in Iraq. In peace-time the great trouble in that country is to find amusement for the men in the evening to protect them from malaria and other diseases. Great attention is paid to hygiene in the training of the Force, and the orderlies, being themselves craftsmen, like all in the R.A.F., spend much of their spare time in making instructional models. Wounded and sick are now carried by air in service types of aircraft, not in flying ambulances, and this is found to be both comfortable and economical.

This report appears 11 months after the one for 1927.

BLOOD-GROUPS IN PUERPERAL AND NEONATAL DISORDERS.

THE blood of mother and fœtus may differ from one another in group constitution, and from time to time it has been suggested that an incompatibility in respect of iso-agglutinins and agglutinogens has some bearing upon disorders of the puerperium and of the first few days of life. In a series of 152 observations on mothers and their newly-born children, E. Bansillon,[1] of Lyons, found 30 cases in which the red cells of the child were agglutinated by the serum of the mother. In 20 (about 55 per cent.) of these the pregnancy had been characterised by severe vomiting beyond the third month, albuminuria, headache, and other so-called eclamptic symptoms. In a parallel series of 121 cases in which the maternal serum was incapable of agglutinating the fœtal red cells these symptoms only appeared in 16 (about 13 per cent.), though in one of them the symptoms were "graves avec eclampsisme." The converse case of agglutination of the maternal red cells by the fœtal serum was investigated with special reference to its possible relation to icterus neonatorum. In a series of 155 observations, 22 cases were found in which the fœtal serum was capable of agglutinating the maternal red cells. In 15 (or nearly 69 per cent.) of these the child showed marked jaundice during the first three days of life. Among 133 children whose serum was incapable of agglutinating the maternal red cells, icterus showed itself in only 10 (about 7 per cent.). Despite his suggestive findings, Bansillon remains sceptical about the possibility of a relationship between "eclampsisme" and incompatibility of maternal and fœtal blood. But at any rate he seems to have made out a case for further inquiry into the possible relationship between icterus neonatorum and agglutinability of the maternal red cells by the fœtal serum.

RECONSTRUCTION OF THE ROYAL VETERINARY COLLEGE.

THE importance to the State in an agricultural country of an efficient veterinary service is so obvious that it is not surprising that the Royal Veterinary College, four years after its foundation in 1791, became the recipient of a grant from Parliament of £1500 yearly. What is far more remarkable is the fact that after the year 1815 the grant was withdrawn, and that since then the College has been maintained only by donations and the relatively small sums represented by the fees of the students. The Development Fund gave a sum a few years ago for the erection of a Research Institute, and annual grants have been received from the Ministry of Agriculture and Fisheries for the maintenance of this department; but the school itself has meanwhile fallen into so serious a state of dilapidation that it is in danger of closure from lack of funds. It is scarcely a reasonable policy to encourage research while so vigorously discouraging the coming generation of research workers. Some of the educational buildings have already been condemned as unsafe, while the annual expenditure on repairs is a formidable drain on the straitened resources of the College. In the appeal for funds made three years ago by the Royal Veterinary College it was noted that in France and Germany the maintenance grants for the veterinary colleges in a single year before the war exceeded the total amount given by successive governments for veterinary education in England and Wales during the last 100 years.

In a recent report[1] on the Reconstruction of the Royal Veterinary College the Departmental Committee of the Ministry of Agriculture and Fisheries comment on the unselfish work, under deplorable conditions, of the members of the teaching staff and advises complete reconstruction and reorganisation as the only means of ensuring the continued existence of the College. The report deals comprehensively with the factors to be considered in the construction of the proposed new college, with special attention to site, accommodation, curriculum, staff, and government. The present buildings at Camden Town suffer from constriction and noise of traffic, but have the advantages of a central position and proximity to Islington Cattle Market, University College, and the London School of Tropical Hygiene. A town site, the committee consider, is preferable to a site in the country, since larger numbers of cases pass through the College for treatment, and though these are mainly cats and dogs and horses the experience of students in the treatment of farm animals can be supplemented by residence with practising veterinary surgeons and farmers during the vacation. It is doubtful whether a country site would command a greater number of farm animals than may be brought to a town clinic by motor ambulance, while a decrease in the numbers of small domestic animals would be inevitable. Familiarity with large numbers of sick animals is essential to the student, and can clearly be best obtained in towns. Another advantage of the present site lies in the fact that the College will probably become affiliated to the University of London, when the opportunities for recreation and social intercourse among the students would be much increased. It is proposed to provide for an annual entry of 75 students, including women, who were only admitted to the College in 1927—with total accommodation for 250; and to offer a four-year course, as at present, in preparation for the Diploma of the Royal College of Veterinary Surgeons. The report emphasises the desirability of a close connexion between the educational and the research departments of the institute, and the architectural construction of the new buildings would be designed to encourage this. A considerable increase in the staff is strongly advised with corresponding additions to equipment and maintenance; the new buildings are intended to provide ample laboratory and class-room accommodation with space for wards, operating theatres, and X ray apparatus. The estimated approximate cost of the new building, including equipment, is £280,000—or £300,000 if the freehold of the present site and certain neighbouring land can be obtained. The cost of maintaining the new College is estimated at £21,000 per annum, and an increase in the grant to the Research Institute from £5000 to £25,000 per annum is advised, with a view to providing a field station near London for experimental work on larger animals.

The response to the appeal for funds made by the governing body during the last three years has been disappointing, only £30,000 having been collected, and though the Treasury have sanctioned a grant of a sum not exceeding £35,000 for erecting new buildings, this grant is subject to the condition that the governors must provide an equal sum for every £1 received.

[1] Jour. de Méd. de Lyon, Oct. 5th, 1929, p. 637.

[1] London: H.M. Stationery Office. 1929. Pp. 26. 1s. 3d.

Even so the funds at present fall lamentably short of the advised outlay. Those who have had the opportunity of inspecting the magnificent veterinary institutes subsidised by the State in other parts of the Empire—for example, that organised at Onderstepoort, Pretoria, by Sir Arnold Theiler—will support the demand for an adequately equipped and staffed College in this country, where the lack of proper facilities for training reacts on the status of the veterinary surgeon.

AN ENGINEER ON INDIAN SANITATION.

In tropical countries especially medicine has frequently to call in the aid of the engineer, and the views of an Indian sanitary engineer of outstanding experience are, therefore, of considerable interest to all medical men who practise in warm climates. Mr. G. Bransby Williams, formerly chief engineer of the Public Health Department of Bengal, has on two occasions addressed the Rotary Club of Calcutta on the subject of public health in India, and his last address, delivered in June of this year, contains a great deal to provoke thought. It is not difficult, in most parts of India, to produce vital statistics, which, from a European standpoint, are appalling, and Calcutta maintains an unenviable lead in this respect. The advantages of improved hygienic conditions may be worked out in terms of rupees, as well as of physical and moral advancement; this has been frequently done, and we need not elaborate that side of Mr. Williams's address, but other aspects are worthy of study. He begins by referring to the stupid as well as rather brutal attitude of a certain type of pseudo-philosopher, who turns down attempts at social and hygienic betterment, with the argument that to interfere in these matters is to disturb the balance of nature, and that as India is over-populated, it is unwise to take steps to lower the death-rate. It may be true, as David Harum held, that a moderate amount of fleas are good for a dog, inasmuch as they keep him from brooding over being a dog, but a laissez-faire attitude should not prevent us from trying to envisage an India which is not only more healthy, but better fed, better housed, better educated, and more generally prosperous than at present.

Mr. Williams tilts against official inertia in sanitary matters. He points out that the expenditure on water-supply, antimalarial measures, and public health generally in India is ridiculously small, and he adduces instances of gross neglect by responsible official bodies. The drainage outfall of Calcutta, it appears, is being allowed gradually to silt up, without any serious effort being made to keep it open. The neighbouring town of Howrah, with 200,000 inhabitants, has been permitted to develop on village lines, with no proper sanitation at all. Calcutta itself is growing increasingly unhealthy, as shown by the mortality figures, and it is to be feared that the same is true of some other large centres. On these and similar grounds Mr. Williams comes to his main thesis, which is that, as regards any serious improvement in the health of the inhabitants, the results of the British administration have been to a great extent a failure, no advance having been made comparable to that in Great Britain and other western countries. The fault, he admits, lies largely with local authorities, and unless a new atmosphere can be created, he believes that conditions are likely to get worse than better, with a further broadening of popular control. As a start he advocates the institution of large-scale experiments by public health and engineering authorities in specially insanitary areas, with a view to prophylaxis of disease.

There is, of course, another side to the picture which Mr. Williams draws. Small-pox has been definitely controlled, cholera has been checked in many of its worst manifestations, and the resources of modern science have been made available for anyone who has the initiative to use them in regard to malaria, tuberculosis, kala-azar, diphtheria, and other diseases. The path to general sanitary improvement has been indicated, and the influence of the British administration has always been exerted in favour of medical and public health reforms. More advanced communities, such as the Parsis of Bombay, have availed themselves largely of the opportunities provided, with immense profit to their section of the population. Large scale demonstrations of modern sanitation do exist in cantonments and the larger urban centres, and in some rural districts in the form of tea and rubber plantations, many of which are models of sanitary, as well as industrial, organisation. Such examples might with advantage be multiplied many times over, but the root of the whole question is, of course, education, not merely school and university education, but simple instruction in the homes of the people, and more particularly in the quarters of the women. In Gurgaon Mr. Brayne has shown what can be done by appropriate propaganda. "When you lose your way in Gurgaon district you find your way by your nose. The greater the stink the nearer the village. Even the animals clean their young, and do not foul their nests by insanitary habits. Why are Gurgaon villagers worse than animals?" By means of such simple home-truths has the deputy commissioner of Gurgaon appealed to his flock, who have shown themselves not devoid of humorous appreciation, and have responded in practical fashion.

A LABORATORY TEST FOR SMALL-POX.

Diagnosis of the mild small-pox prevalent in this country is sometimes difficult, especially at the beginning of an epidemic when there have been no previous cases to make the practitioner suspicious. A laboratory test of proved diagnostic worth would be very useful in the diagnosis of atypical cases and therefore of great help in the control of epidemics.

In 1925 M. H. Gordon demonstrated that the virus of small-pox gave both specific complement fixation and flocculation with an antivariola serum. His evidence was convincing and its practical application is now forthcoming in a report[1] by Dr. W. L. Burgess, Dr. James Craigie, and Prof. W. J. Tulloch on the application of the flocculation test to the diagnosis of small-pox. The reaction is carried out with a suspension of the crusts from a suspected case and a specific flocculating serum prepared in the rabbit. The material was obtained from 93 cases coming from three different localities, Dundee, Arbroath, and South Shields. Fifty-three of these were cases of small-pox, which with one exception were of the mild type, and many of them presented considerable difficulty in clinical diagnosis. The remaining 40 constituted the control material and consisted of 11 cases of vaccinia (bovine 4, rabbit 5, human 2), 27 cases of chicken-pox, 1 case of impetigo, and 1 of septic rash. The results of the flocculation test were correlated with the clinical and epidemiological evidence, and the authors of the report conclude that the reaction is specific and of diagnostic value. In this they seem to be entirely justified and they are to be congratulated on an eminently satisfactory piece of work. But the importance of this investigation is not only a practical one, for it throws light on the mechanism of the immunity reactions of filtrable viruses. From his work with the viruses of vaccinia and variola Gordon claims that the immune reactions of bacteria and filtrable viruses are fundamentally the same and in this he does not stand alone. His position has been assailed, however, by certain investigators—notably Schultz and his co-workers in the United States and C. H. Andrewes in this country. Schultz and his colleagues fail to find any specificity in the complement-fixation and agglutination reactions obtained with viruses and their antisera, and they think that these reactions are attributable to contaminating bacteria present in the virus suspensions. Burgess, Craigie, and Tulloch have done control experiments with sera prepared against the bacteria found as contaminants in their virus material and their results do not support Schultz's contention.

---

[1] Diagnostic Value of the "Vaccinia Variola" Flocculation Test. Medical Research Council Special Report Series, No. 143

This report is a valuable contribution to the literature of filtrable viruses and, as the Medical Research Council points out in the preface, it demonstrates the value of investigations carried out in the field by a medical officer of health in close coöperation with laboratory workers.

THE PREPARATION OF CATGUT.

CATGUT, to the preparation of which for surgical use the Medical Research Council have devoted a special report,[1] was certainly used by Galen for sutures, and, during the Middle Ages, by a number of surgeons; but it was not until the 'sixties of last century, when antiseptic surgery was devised by Lister, that it became an important material in surgical practice. It was then recognised that the elastic layer of the small intestine of sheep (for cat denotes not the source of the gut but the use to which it was first put, if it derives from an old word for fiddle) possessed many of the qualities which are desired for ligatures and sutures. First of these is a tensile strength commensurate with its gauge, a measure of elasticity, and the retention of these qualities for a long time. Its absorbability has a value which varies with the purpose to which it is put. Its great drawback is the difficulty of rendering it sterile, many of the methods which have been invented for the purpose having proved ineffective. From its place of origin catgut is obviously apt to be contaminated with many germs, some of which may be harmless while others may lead to serious infection. It is clear from the report that the large majority of the methods hitherto employed do not produce an absolutely aseptic gut, whether the test is made for germs naturally present in the gut or for specially virulent organisms introduced by intention. Nevertheless, it is a fact that surgeons have been able nearly always to obtain perfect results without any wound infection by the use of these methods, the tissues being capable of dealing effectively with a slight degree of infection, just as in pre-antiseptic days suppuration did not necessarily follow operation, even when unsterilised ligatures and sutures were buried. But at the present time no surgeon should be satisfied with suture material which can possibly contain living germs. The earliest attempt to destroy the organisms completely was made by Lister, who steeped catgut for some hours in a solution of carbolic acid, with perfect results from the surgical point of view; later he employed a mixture of dilute carbolic acid and olive oil; mercuric salts were soon substituted, and it will be news to many to learn that of these the biniodide is decidedly less powerful than the perchloride. Chromic acid was next tried, then various compounds of silver, turpentine, sundry essential oils, and other substances. Finally came iodine, which in one form or another has received the greatest measure of support. With nearly all these substances the test of efficiency was clinical; one and all produced a catgut which, in the great majority of operations, allowed the wound to heal without suppuration or any other sign of infection. The bacteriologist can, however, find infective germs in the gut every time. An essential difficulty in examining the claims of a particular antiseptic resides in the fact that, before the test can be applied, every trace of the chemical must be removed from the gut, for otherwise it may inhibit the growth of some germ which is actually present. No amount of washing with water will effect this, a point in which many investigators have failed. After an exhaustive survey the authors of the report give their adherence to iodine as a sterilising agent, combined with meticulous care at every stage of the process, from the earliest. If immersed for nine days in a solution of iodine of suitable strength at an early stage of preparation, catgut will absorb 12 per cent. of its own weight of oidine. If the iodine is in excess the gut becomes brittle, and it is necessary to remove some of it from the ligature after it has been sterilised. Flexibility is enhanced by adding glycerin to the iodine solution. All who prepare catgut ligatures and all who use them will need to pay attention to the conclusions reached in the report.

THE ADMINISTRATION OF NATIONAL RADIUM.

THE Radium Commission has decided, for the present, to recognise as national radium centres only such places as possess medical schools with complete clinical courses and the necessary facilities for instructing students and post-graduates in the principles and practice of radium therapy. In the view of the Commission, the need for more trained and qualified workers in the use of radium is even more urgent than the supply of radium itself. The Commission has further decided to initiate all negotiations for the constitution and equipment of national radium centres through the medical faculties of the local Universities concerned, and this procedure is now being followed. When the claims and requirements of these centres have been considered and assessed by the Commission, the allocation of national radium will be commenced. About 8 g. should be available for distribution, on loan, by the end of this year, and another 7 g. before the autumn of 1930. It is estimated by the Commission that practically all the radium which can be purchased by the Trust with the funds already subscribed will be required for the equipment of the national radium centres, and it is regarded as unlikely that any of this national radium will be available for allocation to other hospitals or institutions.

The radium for the "4-g. bomb" has been received from Belgium, measured and tested by the National Physical Laboratory, and handed over to the authorities of Westminster Hospital, where it has been installed. If, after three months, the radium is purchased, it will be entrusted for a further period of three years (at a rental of £410 per annum) to this hospital, which will maintain a continuous day and night service with the bomb, in the pursuit of certain clinical objectives prescribed by the Commission. A radon plant is to be installed at the National Physical Laboratory for the purpose of supplying radium emanation to institutions which otherwise could receive no direct assistance from the Commission in connexion with radium therapy. Questionaires relating to this service are being framed.

TUFFIER.

THE death in Paris last week of Sir Théodore Tuffier at the age of 72 years has removed from us one who upheld a great surgical tradition and who has been described in the *Siècle Médical* as worthy of the title "A Prince of Science." Tuffier had been for more than 40 years surgeon to Paris hospitals, but his name and fame were attached especially to the Hôpital Beaujon and the Hôpital de la Cité du Midi. There was hardly a province of surgery in which he did not do pioneer work; the development of spinal anæsthesia was perhaps the major interest of his life, with the surgery of the lung coming scarcely second. His published works on renal tuberculosis, on uterine fibroids, and on the treatment of inoperable cancer commanded general attention. He was a great traveller and was familiar at first hand with surgical practice all over the world. Conversely his own surgical clinic at the Cité became a centre of attraction for surgeons of all nationalities. Early in the Great War Tuffier was brought into intimate relations with the surgeons of the British Expeditionary Force, of which we have personal testimony from Sir George Makins, who was senior consulting surgeon to the Force. When at the suggestion of Mr. Lloyd George the Conférence Interalliée was instituted to discuss the methods of surgical treatment in favour amongst surgeons of the allied armies, it was arranged that the meetings should take place in Paris, and Tuffier was elected president. Into the organisation of these meetings he entered with great enthusiasm and he made an effort to keep the work alive between the official meetings by monthly gatherings at his own house. There can be no doubt, Sir George Makins, writes, that these discussions had an important influence not only on the diffusion of experience gained in the different armies, but also on methods of treatment, hospital organisation, and the transport of patients. Tuffier himself was so impressed by the value of these international meetings that he made efforts to continue similar conferences after the war, and in fact the fifth of such meetings was held in London this year. Tuffier was an early and ardent adherent of the method of treatment of wounds devised by Carrel and Dakin, and speedily introduced it into the French hospitals. Always eager to adopt new ideas, he was the first surgeon to transport a patient by aeroplane, and thus brought a man wounded in the chest over the lines of the enemy to a base hospital in North Africa. A man of great personal charm, of high culture, a good linguist and conversationalist, Tuffier was also most hospitable. Many British surgeons in Paris during 1914–18 remember with pleasure visits to his home, where he had accumulated a wonderful collection of pictures and objects of vertu of all kinds. For over 25 years Tuffier was associated with the work of the Hertford British Hospital in Paris, first as surgeon and later as chairman of committee. The British Government recognised his services uring the war by creating him a Knight of the British Empire and a Companion of the Bath. His eminence as a surgeon had already been recognised by his colleagues by his election in 1913 as an honorary Fellow of the Royal College of Surgeons of England.

MEDICAL TREATMENT OF EXOPHTHALMIC GOITRE.

OF late years a mass of reports on the successful use of surgery in long series of cases of exophthalmic goitre has overshadowed other methods of dealing with this disease. But operative treatment, although it produces a certain benefit in a certain time, is admitted to be unsound at bottom, and we turn with interest to an account of the end-results of medical measures in 2000 cases studied during a period of 19 years, and now described by Israel Bram.[1] In this series care was taken to differentiate between, on the one hand, toxic adenoma with secondary Graves's disease, which was treated surgically, and, on the other, true Graves's disease, which was treated medically. The medical treatment was on the following lines. Rest was deemed important, but unless there were serious cardiac lesions the patient was allowed to get up for three hours in the morning and also in the afternoon. Special attention was paid to home environment, and when harmony was lacking sanatorium treatment was given. A properly equipped sanatorium, at a moderate altitude, where dietetic, sociological, psychological, and medical supervision can be suited to individual needs is next best, says Bram, to a congenial home. The diet was ample—about twice as much as for normal people—but low in animal protein. Drug treatment was mainly symptomatic; quinine salts, ovarian products, suprarenal cortex, and mild sedatives were found useful, whilst care was taken to avoid the use of thyroid extract, the opiates, iodides, and digitalis. Psychotherapy was regarded as a vital part of the treatment, and every effort was made to clear up conflicts of internal or external origin. The patients were discharged from active treatment in from 2 to 18 months, the average for all cases being 8 months. Those who were able to relax properly made much more rapid recovery than those who were weighed down with household or other duties. In 20 per cent. of the series surgical treatment had been resorted to months or years previously. Some of these had derived temporary benefit from partial thyroidectomy and others had not improved. It was found (contrary to general opinion) that post-operative cases with myxœdema tolerated thyroid extract almost as badly as those without any such signs of insufficiency, the only effect of the thyroid extract being to cause a flare-up of the still persisting symptoms of Graves's disease. The cases were followed for from three to ten years, and in recording the results the verdict of complete recovery was accorded to patients whose pulse-rate, basal metabolic rate, and weight were normal, who had no tremor, no exophthalmos, and no enlargement of the thyroid, and who had a feeling of perfect well-being and a normal endurance for social and economic purposes. It is stated that according to these criteria recovery took place in 91 per cent. of the 2000 cases, whilst 3 per cent. were completely cured but for slight persistence of the exophthalmos, 3 per cent. had residual enlargement of the heart without subjective symptoms, and 3 per cent. had signs of myxœdema with or without cardiac enlargement. The latter were cases in which thyroidectomy had been done months or years before regular medical treatment was started. Recurrence of the disease months or years after the patient was considered cured was unknown in the series, and Bram thinks that with treatment on these lines a patient "instructed in the art of relative simplicity of mental and physical existence" is unlikely to develop the disease again in later life. He holds that the main cause of failure in medical treatment is insufficient study of the individual as a whole, and the spirit of haste in which medical treatment is only too often carried out.

OUR MEDICAL LAUREATE.

Dr. Bridges, having appealed, in the words of Virgil, for the support of his adored Muses, testifies in this earnest difficult poem[1] to a life-long love of beauty, seeing that with the world's attainment of accumulated knowledge new orders of beauty arise; but a devotion to Greek culture compels him to regret that man's faculties have not developed in a comparable manner, so that there is "now no higher intellect to brighten the world than little Hellas own'd." The poet's deep religious feeling, however, and, wittingly or unwittingly, the humanism pertaining to his profession, lead him to point out the limitations to the Greek ideals. From this introduction the poet, in a second book, goes on to review the war history of the world, finding it an expression of the "Autarchy of Selfhood . . . by Reason denounced"; while in a third book he considers Breed, the second and "younger of the two arch-instincts of man's nature." Here medical knowledge is freely used in thought and word, and a similar ability to employ correctly the vocabulary and reasoning of the physiologist and the psychologist will be found in Ethick, the closing book.

We have here a religious appeal written in austere and beautiful language, with an effective disregard for the rules which used to govern the making of Alexandrines. Perhaps prosody as much as poetry lies without our proper sphere of criticism, but upon orthography we may express opinion. The approach to a simplified spelling employed by the poet in his text does not follow a logical pattern.

THE next session of the General Medical Council will begin at 2 P.M. on Tuesday, Nov. 26th, when Sir Donald MacAlister, the President, will take the chair and give an address.

THE Lloyd Roberts memorial lecture will be delivered at the Royal College of Physicians of London at 5 P.M. on Thursday next, Nov. 14th, by Mr. H. A. L. Fisher. The subject is An Oxford Movement.

LI.

THE INTERPRETATION OF TESTS OF STERILITY AND FERTILITY IN THE MALE.

UNTIL recently the only test to which the male has been subjected in cases of childlessness in marriage has been the examination of the semen for the presence of living spermatozoa. If these were found in what appeared to be reasonable numbers the result was considered satisfactory, and on the female partner in the marriage was placed the responsibility for the absence of children. But of recent years this method of dividing males into two classes of sterile and fertile has been found to be insufficient. It has been realised that a failure to conceive may be the result of a relative as opposed to an absolute sterility on the part of one or both of the partners in marriage. Even a minor degree of impairment of fertility in the male may, if he be united with an unfertile partner, become of supreme importance. Childlessness is, in fact, the result of the sum of the impaired fertility of husband and wife. This being so, a report on the husband should, if possible, furnish information as to his relative fertility, as well as the mere statement whether the semen contains active spermatozoa or not.

Examination of a Condom Specimen of Semen.

The quantity of semen emitted at a single coitus varies in different individuals, and at different times, and oligospermia is only of importance if of marked degree, and if it is known that a week's abstinence has been observed prior to the taking of the specimen. Oligospermia is physiological in old age. In a younger man it suggests suppression of prostatic secretion, and indicates the necessity for a careful examination of that organ. If in addition to oligospermia pus cells are found in the semen, an old-standing chronic prostatitis is a possible explanation. Finally, it should be borne in mind that the wearing of a rubber sheath may interfere with coitus in a nervous male and be responsible for the scanty emission. For this reason two or three specimens should be examined before oligospermia is reported.

Hæmospermia.

Hæmospermia suggests the presence of a chronic inflammation or congestion somewhere in the seminal tract, and more especially in the vesicles. It has also been found in cases of prostatic enlargement and in association with certain blood diseases, such as scurvy. If the blood is uniformly mixed with the semen, the vesicles are more likely to be implicated; if less completely mixed, the posterior urethra. In many cases of hæmospermia no lesion of the genital tract can be found, even after a searching examination.

Pyospermia.

The presence of pus points to an infection of the seminal tract. The same deductions may be made from the mixing of the pus in the semen as in the case of blood. In the presence of pus spermatozoa commonly lose their mobility and die. But the action of pus on the spermatozoa is very variable, and sometimes pus is found in the semen of fertile men. It is indeed probable that it is not the pus itself which is harmful, but that the pus is evidence of an inflammation which renders the secretions unfavourable to the life of the spermatozoa.

Necrozoöspermia.

The length of time that spermatozoa remain active and living after emission is affected by numerous factors. Some of these depend on the nature of the secretions surrounding the spermatozoa and some on the care taken to maintain the specimen at a uniform body temperature. The duration of life after emission may, however, be taken as a measure of the vitality of the spermatozoa. It can be studied by putting a drop on a slide under the microscope without any attempt being made to keep it warm, or else by placing the whole specimen in an incubator at body temperature and examining a drop from time to time. The presence of various types of deformed spermatozoa in a specimen is usually indicative of a hostile prostatic or vesicular fluid. If only dead spermatozoa are found at the first examination a fresher specimen should be obtained in order to discover whether the spermatozoa are dead at the time of ejaculation or whether they have died rapidly on account of unfavourable surroundings. The presence of blood, pus, and especially of micro-organisms in the semen, often explains a poor viability, especially if its reaction is found to be acid. In any case, necrozoöspermia is an indication for the need of a careful overhauling of the seminal tract for signs of inflammation.

Oligozoöspermia.

It is in richness in spermatozoa that the greatest number of variations are found when different specimens of semen are examined. Up till recently only large deviations from what was roughly considered the normal have been considered. Recently, however, Drs. Donald Comber and Morris Sanders have devised a method of spermatozoa counts, which expresses numerically the relative fertility of the male. These observers found that the average count in a healthy male is 100,000,000 spermatozoa per cubic centimetre. This figure remains fairly constant for the same individual at different emissions. It is diminished after sexual excesses or as the result of severe illness. It is lower in elderly men than in those still in their physical prime. As a general rule it is higher in those with large, well-developed testes than in those with small testes.

Anything that interferes with the formation of spermatozoa, or with their passage into the urethra, may produce an oligozoöspermia. The discovery of a low count in a young man should lead to a very careful examination, not only of the genital tract, but of the body as a whole. The testis is extraordinarily sensitive to changes elsewhere in the body, and treatment of any abnormality, be it a glandular defect or a septic focus, may have as a result an improvement in the spermatozoa count. The importance of oligozoöspermia as a factor in childlessness may be gauged by the fact that in only four of the 294 cases examined by the above quoted investigators did conception occur when the count was under 60,000,000.

Azoöspermia, or the complete absence of spermatozoa in the semen, may be explained either by a complete aspermatogenesis or else by a failure on the part of the spermatozoa to reach the urethra. The crucial test by means of which these two conditions may be distinguished is puncture of the testes and examination of the aspirated testicular fluid. This may be done under local anæsthesia. If no spermatozoa are found in the testicular fluid a search should be made for some constitutional defect, special attention being paid to the endocrine glands. If spermatozoa are found, the obstacle to their egress must be located by posterior urethroscopy and tests of patency of the ejaculatory ducts. This may be conveniently done by injecting a dye such as methylene-blue into the vasa at the neck of the scrotum and noting whether it appears in the urethra.

Statistics show that gonorrhœa is generally responsible for these cases of azoöspermia due to obstruction. Especially is this likely to follow bilateral epididymitis, as is shown by H. Benzer's observations on the after-history of German soldiers who had suffered from gonorrhœa and had been married for three or more years. He found that of those who had previously had unilateral epididymitis

23·4 per cent. were childless, and of those who had had bilateral trouble 41·7 per cent. In view of this risk of sterility it would be wise for all men who have suffered from bilateral epididymitis to submit a specimen of semen for examination before marriage. An azoöspermia of this nature is more likely than not to be incurable and a woman who marries a man in the hope that she may have children and discovers later that she can never be a mother may well have grounds for complaint if her husband, knowing the risk of sterility, has never submitted himself to examination. The same precautions should be advised where there is a history of epididymitis from other causes than gonorrhœa, or of orchitis following mumps.

General Consideration.

It must be remembered that in the case of the childless marriage multiple causes are the rule rather than the exception. The examination of the semen, therefore, although it is of great assistance in assessing the fertility of the male, is not the sole test to which he should be subjected. Constitutional factors that depress his fertility must be sought for. According to S. R. Meaken, the incidence of these constitutional faults is even greater in the male than than it is in the case of the female. Any examination, therefore, which helps us to assess the general physical health of a husband, for example a Wassermann, may be regarded as a test of fertility, although in this article only the examination of the semen has been considered.

KENNETH WALKER, F.R.C.S.,
Genito-urinary Surgeon to the Royal Northern Hospital and St. Paul's Hospital.

Special Articles.

REPORT ON AN OUTBREAK OF SICKNESS DUE TO CONTAMINATED MILK.

BY ARTHUR MASSEY, M.D., D.P.H. LEEDS,
DEPUTY MEDICAL OFFICER OF HEALTH, CITY OF LEEDS; HON. DEMONSTRATOR IN PUBLIC HEALTH, UNIVERSITY OF LEEDS.

THE outbreak occurred in the Roundhay and Moortown districts of Leeds on Sept. 30th last. There were involved 83 children, all of whom were under ten years of age. Of those affected, 78 were pupils at two elementary schools, A and B, in the city. The remaining 5 cases were children under school age of private families in receipt of milk from the same source as the two schools in question. The schools concerned, in common with the other Leeds elementary schools, receive a daily supply of milk in accordance with the scheme recently adopted by the Leeds Education Committee, which scheme commenced to operate on Sept. 9th last. Under the scheme, milk is provided to the schools by various purveyors according to district, and at the present time some 7000 gallons per diem are supplied in this way. One of the affected schools (A) receives 3 gallons, and the other (B) 1½ gallons per day. The milk is delivered to the schools each morning in capped bottles of one-third of a pint capacity, and straws are provided. The modus operandi is that the straw is thrust through a central thin portion of the cap and the milk is drunk through the straw. The milk supplied is non-graded and unpasteurised. The bulk quantity required under the scheme is such that much of the milk has perforce to be brought from without the city.

Source of Production.

At the time of the outbreak the affected schools were supplied with milk by a duly registered retail purveyor X, whose premises are situate within the city. The source of production was a farm outside the Leeds boundary occupied by Y. The milk was brought in churns from farm to dairy, bottled at the latter place, and finally delivered at the schools between 9 A.M. and 10 A.M. X had supplied the two schools in question (no others) since Sept. 16th, but it is to be noted that the day of the outbreak, the 30th, was the first on which milk from Y's farm was delivered at the schools. Prior to Sept. 29th, X had obtained his milk elsewhere, and there had been no untoward incident. On the 29th X obtained his first supply from Y. The day being Sunday, and the schools closed, the milk was delivered loose to private customers only. On Monday morning, before the school outbreak occurred, X learned that three young children on his round had the previous day suffered sickness which their parents attributed to the milk. The same day X delivered milk in bottles to the schools and loose to his private customers. There followed the school outbreak, and at least two cases of sickness in children on his private round.

On Sept. 30th at (A) school, 77 children partook of the milk; of these, as far as could be ascertained, 71 were affected, of whom it is certain 55 suffered severe vomiting. Six only of those who had taken milk were quite unaffected. None of the children who had not taken the milk was affected. At (B) school 39 children drank milk, 7 of whom suffered subsequent vomiting. At this school it was not possible to ascertain the number of children who drank milk and suffered consequent indisposition other than vomiting. Again there was no sickness among those who had not partaken of milk.

Characters of the Illness.

In both schools the milk was consumed at 11 A.M., and in the large majority of cases the sickness commenced about 1.30 P.M. Persistent vomiting was the most prominent feature, while mild diarrhœa and abdominal pain occurred in a few cases. Prostration was marked in isolated instances, necessitating the removal of the children from school to their homes by motor-car. The symptomatology indicated a condition of severe irritation in the upper alimentary tract.

On Oct. 1st the houses of 50 of the cases were visited by officers of the Leeds Public Health Department. It was elicited that, of these 50 children, 14 had stated that the milk tasted "funny" or "a bit sour," while all others had said that they had noticed nothing amiss. All concurred as to the normal appearance of the milk. Of the 50 cases, 6 commenced to be ill 2¼ hours after taking the milk, 30 2½ hours after, and 5 three hours after. According to the histories given by parents or children concerned, in 5 cases the illness lasted two hours, in 6 cases three hours, in 26 cases four hours, in 4 cases six hours, and in 9 cases seven hours. Howbeit all were fully recovered by the next morning. The comparatively short lapse of time between the ingestion of the milk and the appearance of symptoms suggested the action of a chemical poison, or of bacterial toxins already present in the milk at the time of consumption. The limited duration of the resultant illness was probably due largely to the rapid onset of severe vomiting which allowed of more or less prompt evacuation of the offending material.

Of the milk delivered to the affected schools on Sept. 30th all was consumed with the exception of the contents of one bottle. The available sample was divided into two parts, one of which was submitted for investigation to the Leeds city bacteriologist, and the other to the city analyst for chemical examination. The results of these inquiries are given below.

Conditions of Dairy and Farm.

The dairy through which the offending milk was supplied is a well-constructed brick building of 18 by 12 by 10 feet internal dimensions. The walls are of plaster and limewashed, the floor is of concrete, lighting and ventilation are adequate. Town's water is laid on. The sink is trapped and cut off, the waste-pipe discharging on to an outside gully. The dairy is fitted with a gas-heated hot water boiler for treatment of bottles and utensils. The bottles for school milk are brought from the school about noon each day (there is no duplicate set). They are thereupon rinsed and placed in cold water to soak. They are subsequently washed and brushed out with hot water, rinsed in cold water, and finally placed neck downwards in suitable racks to drain and dry. There has been no actual sterilisation by boiling or by steam. No chemical is employed in the cleansing process. The dairy fittings and utensils were found in a satisfactorily clean condition, which is in accord with previous findings.

The farm, which constituted the source of supply of the milk in question, had been occupied by Y for some few months only. The farmer had but commenced to produce and sell milk on Sept. 20th, having purchased the necessary herd of cows within the previous week. He was not at the time registered with the appropriate local authority as a milk producer. The cowsheds at the farm are two in number, and both were found extremely dirty. The larger shed has recently been reconstructed, and in that respect is satisfactory. The smaller requires improvement in paving and lighting. The farmyard was dirty and muddy, but no manure was present. The water-supply is derived by pumping from a deep well, and the supply is described as abundant, and has since been found to be of good quality. There is no milk room and no cooler. The farmer stated that his practice was to stand the filled churns in a trough of water. The milk produced on the evening of Sept. 29th (that which was supplied, through X, to the schools on the following morning) was cooled in this primitive way. As far as could be ascertained, the churns, while so standing in the water trough, had had their lids properly in position. The churns seen at the farm were of the approved pattern. The churns and utensils are cleansed in the yard near the house by water from the well. It was ascertained that the cows were being fed on certain proprietary "dairy cakes." The farmer stated that all the cows had behaved normally with the exception of one which had arrived at the farm on Sept. 27th, and which had had slight diarrhœa which was promptly checked by modification of diet. The cows are milked by the farmer himself, with the assistance of one cowman. Both milkers were found to be in a healthy condition. It was apparent, however, that no precautions were taken by the milkers in regard to cleansing of hands and udders. The cows at the farm are 15 in number. They were duly examined on the morning of Oct. 1st, and the following are the chief points from the report of Mr. J. A. Dixon, the chief veterinary officer to the Leeds Corporation, viz. :—

Fifteen cows were examined, all of which were rather dirty about their udders and teats. The farmer stated that four of these cows had calved during the past week, whilst a further five had calved during the week before. The majority of the cows bear on their teats small scars, the sequelæ of variola. One red cow which calved about a fortnight ago still retains her fœtal membranes, and is discharging a purulent fluid per vulva. She is also affected with chronic suppurative mastitis in the right forequarter, and acute suppurative mastitis in the left forequarter, but her hind quarters are apparently healthy and the cow has a normal temperature. The farmer stated that the milk of this cow has not been put in the churns, but has been fed to the pigs since she calved. With these exceptions all the cows appear healthy.

In view of the conditions found at the farm, steps were taken to ensure an immediate cessation of the milk-supply therefrom into Leeds, until such time as an assurance was forthcoming from the appropriate county authority that the provisions of the Milk and Dairies Order with regard to the methods of production and handling had been complied with.

Bacteriological and Chemical Reports.

On Oct. 2nd Prof. J. W. McLeod, the Leeds city bacteriologist, reported on the sample of milk as follows :—

"Milk contained 23 million bacteria per c.cm. There are colon bacilli present in 1/100 c.cm., but there are masked by another bacterium which probably belongs to the coliform group, but has very slight fermentative activities. This last bacterium is the predominant micro-organism in the milk. It does not correspond to any of the known pathogenic types."

The result of the city analyst's (Mr. C. H. Manley) investigation, which came to hand on Oct. 3rd, reads as follows :—

Composition.

Non-fatty solids ..	9·12 per cent.		Ash	0·74 per cent.
Fat	4·10	,,		
Total solids..	13·22	,,		

"The sample was uncurdled when received, and had not been heated. My examination has proved the absence of preservatives, metallic poisons and alkaloids. Tests were also made for tyrotoxicon (diazobenzol) with negative results. This substance, which may cause sickness and diarrhœa, is liable to be formed in milk and milk products in the summer time. The normal figure for the ash supports my findings as regards the absence of the non-volatile poisons. The chemical composition of the milk is distinctly above the average. With the observation of the proper precautions governing its production, this milk should compare extremely favourably with others on sale in the district."

Summary and Conclusions.

The outbreak of sickness, although of alarming extent, was short-lived, and complete recovery within 24 hours occurred in all the 83 cases.

Milk was the only common factor in the ætiology, and there can be no doubt that it was causative. The milk was found to contain no metallic poison, no alkaloids, no tyrotoxicon, and no preservative. It was rich in fat, due largely to the fact that it came from a herd of cows, nine of which had calved within the previous fortnight. There is no reason to believe, however, that the chemical composition of the milk was in any way responsible for the outbreak. The bacteriological investigation showed the milk to be grossly contaminated. The bacterial content proved remarkably high, which, per se, would render the milk injurious to young children. The predominating organism did not admit of classification according to known types. The evidence points to bacterial toxins in the milk as the cause of the sickness.

A survey of the evidence, in the attempt to decide between dairy and farm as the source of contamination, would appear to indicate the farm. The conditions there were quite unsatisfactory, and it is evident that the farmer in question took on a contract to supply milk before he was prepared as regards premises and equipment to produce under proper conditions. It is significant that the outbreak occurred on the very first day on which X supplied Y's milk to the schools. X had previously supplied the schools with bottled milk from another source without untoward result. The fact that five cases of sickness occurred in children of X's private customers, to whom the milk was delivered loose, would appear to exonerate the bottles and the process of bottling.

Briefly the outbreak appears to have owed its origin to the fortuitous circumstances of a farmer who supplied milk into the city before he was registered with his local authority, and consequently before the inspectorate concerned had had the opportunity of inspecting his premises and methods of production. Such a contingency is very unlikely to recur.

I tender my thanks to Prof. J. Johnstone Jervis, medical officer of health for Leeds, for permission to publish the above extracts from my official report.

PAYING PATIENTS AT READING.—A nursing home for paying patients has been opened in connexion with the Royal Berkshire Hospital at Reading. A large private house adjoining the hospital has been purchased and so adapted that the rooms occupied by patients look out upon timbered lawns. The home will accommodate 15 patients, eight in double-bedded rooms and seven in separate rooms. The stables have been converted into a massage department.

too long, or appeared before they were due, were the old seven deadly sins, to which must be added fear. People should be taught the dangers inherent in indulgence in certain basic emotions. The same principle of unity applied to thinking: one thought at a time, and that a pure thought, uncoloured by desires or fears. Clear feeling and clear thinking must depend on good habit-formation in early life. This needed concentration and interest, regularity and persistence on the part of the mother, as well as constant watch against relapse. The will would be effectively exercised only through the stimulus of interest, which in the infant was largely vicarious and exercised on its behalf by the mother. Factors endangering the child's growing active interest were fear, lack of love, physical ill-health, fatigue, over-stimulation, and irregularity in household routine. These would distract from habit-formation, and give an appearance of irritability, indecision, and lack of purpose. Later in childhood arose the danger of excessive or too prolonged preoccupation with a habit once formed, so that the child was unwilling to pass on to the next. Preoccupation might occur in the unconscious mind as well as in the conscious if a feeling impinged on a mind unprepared to deal with it. The cure of unconscious preoccupation was the province of the psychiatrist, but its prevention lay in good habit-formation; the feeling had originally been put aside instead of faced, because of laziness or cowardice of mind. To avert the catastrophe, the individual must have an alert courage; its absence was a pointer suggesting dangerous weakness in the mental make-up. Preoccupation, conscious or unconscious, caused a poor response, with insensitiveness of feeling, flabbiness of thought and bodily tone, apathy, lack of decision, and lack of interest in the external world, save in matters related to the points producing the preoccupation; to these the individual yielded too strong and uncontrolled a response. This was an adverse factor in the mental health of those around him, as well as in his own. The key-words of mental health were interest, effort, regularity, concentration, and a capacity to terminate concentration, and intellectual and emotional honesty.

Miss **Hester Viney** spoke from the point of view of the public health nurse, than whom, she said, there was no more zealous, devoted, and effective champion of the cause of mental health. She was in a position to deal effectively with the educational side of this question. Miss Viney regarded the constant calling forth of fear as one of the most important causes of mental troubles, and suggested as constructive measures gardens and play enclosures free from noise and traffic, nursery schools, and safe balconies to all tenement rooms. The principles of mental health should be taught in season and out of season, as those of physical health had been taught.

A paper by Miss E. M. **Lawrence** (Chief Social Worker at the Child Guidance Clinic) was read in her absence. She dealt with the place of the social worker in mental hygiene, and remarked that to many people behaviour was causeless, and had to be taken as it came, and fought against blindly until their difficulties became so serious that some help must be sought. The kind of help they got was critical; the ill-advised went to all kinds of quacks and necromancers; the well-advised went to doctors, but did they always get what they ought to get, even there? The worst-served class were the borderline cases who remained in the community, competing with better people, and bound to be defeated.

The Child and the Parent.

The chair at this meeting was taken by Dr. **Cyril Norwood** (Headmaster of Harrow), who observed that to become a parent was easy, but to get out of it without disgrace was difficult. The relationship between parent and child was largely one of give and take, and a great deal depended on the kind of parent and the kind of child; modern psychology tended always to blame the parent. He mentioned the great importance of the education of the child by other children.

The Rev. L. W. **Grensted** pleaded for greater leisure and quiet, without which the right parental relationship was impossible. We must simplify home life, and limitation of families might in many cases be the only way of securing full and adequate family life. The medical aspects of conception control had been well thought out; the theological aspects had been only too prominent, but the psychological—the most important aspect which would eventually turn the scale—had not received nearly enough attention. He pleaded also for the improvement of children's literature, although it was already much better than specimens like the "Fairchild Family." He referred to the desire of parents to keep their children for ever children, like the dreadful and ominous figure of Peter Pan, the most sinister form the mind of man had created.

Dr. **Helen Boyle** emphasised the value of training a child in adaptability, and the lack of necessity for perfection in parents. Many people, she said, wore themselves to fiddle-strings by trying to be resigned, when a little kicking would do a world of good. The enormous number of suicides suggested that we were not giving our children that faith that can move mountains. Training in adaptability could begin very early, and a healthy baby ought to be taught to sleep under any conditions of noise or light. Children were largely preoccupied by feeling their personal contacts with life and experimenting with happiness, and it was possible to safeguard them too much from the discoveries they ought to make. It did a healthy child no harm to over-eat itself and be sick, and the child thereby learned valuable lessons. A perfectly organised childhood did not produce an adaptable adult. "Of nothing too much" was a safe motto for the upbringing of children. Parents should strive for a large peace of mind; the child also made mistakes—often by trusting too much, becoming disillusioned, and then doubting too much—and most people thought much too badly of themselves, and then compensated by swelled head.

In the course of the subsequent discussion Sir **Maurice Craig** maintained that the ability to sleep under disturbing conditions was an idiosyncrasy, and not merely a matter of training. He congratulated the Middlesex Hospital on its advance in ceasing to wake the patients at 5 A.M., and spoke of the appalling results of mixing big and small boys in dormitories, so that the youngsters were awakened when their elders went to bed. To those who advised "leaving it to Nature," he recommended a study of the garden left to Nature for six months. Dr. **Margaret Lowenfeld** pleaded for more directed attention to play.

The Problem Child.

At this session the chair was taken by Dr. R. H. **Crowley** (Senior Medical Officer, Board of Education), who said that the child's life must be integrated in some way, and that a policy of coöperation between the home and the school was needed.

Miss E. M. **Nevill** (Psychologist to the Children's House, Bow), distinguished three outstanding groups of problem children: disturbers of the peace, reality shirkers—the apathetic, timid, nervous and dreamy—and moral offenders. Adler had suggested three causes: that the child felt himself unloved, or inferior, or that he was spoilt. If with "unloved" one included "misunderstood," and with "inferior," "superior," this would cover most cases, but there was a difficult temperament to begin with, and certain illnesses might play a part. She gave examples of real children, showing how serious trouble might arise from very simple things which could have been easily settled by a little common sense. Much psychology was commonsense. She made a plea for the outstandingly clever child, for whom so little had been done; brilliant children were misfits, even more than dull children. The trouble should be discussed openly and frankly, without emotion, in order to find the cause. The part of the father in the child's life must not be forgotten.

Dr. E. A. HAMILTON-PEARSON said that whether or not a child would become a problem child depended largely, if not wholly, upon its attitude to life, the product of its whole practical experience at any given moment. Attitude, moreover, determined almost exactly the experience of the immediately ensuing period; it caused the results of future experience to be similar to those of the past. Character was the outcome of recurring experience; therefore, if a child was to be able to form a strong character, it must start with a right attitude to life, and for this it must be able to learn right values for its thoughts and actions. An important environmental factor in the causation of wrong attitude was the lack of right, understanding discipline. Parents were too apt to allow children to make decisions for the making of which they had neither the data nor the mental apparatus for fear of repressing their personality. This was a chase after a false ideal; real freedom could only be a psychological state. Stable discipline implied complete freedom between known limits imposed for the good of the majority. The child produced by complete freedom of expression overvalued the importance of its own desires, and the restriction of school life bewildered it, so that often the seeds of neurosis were sown. The educational system created problem children by confining the eager, urgent, and turbulent interest of the young within a rigid and monotonous system, so that work came to be regarded as something unpleasing and to be avoided as much as possible. A rigid contrasting distinction between work and pleasure was a bad attitude for life. The educational system also created problem children by its adherence to a purely intellectual ideal in education. There were several types of mind, and each group of types required a different educational approach. Under the uniform system many children were committed to a dull routine, which daily emphasised their inferiority; they lost resolution, initiative, and confidence, and became the drifters in life. Adequately stimulated interests were the vitamins of the mind: if mental scurvy were to be prevented, the whole educational system must be recast. The refusal of the budding adolescent to grow up was becoming more and more common. Before the war there had been a sharp line between childhood, with its occasional treats and strict obedience, and adulthood with its relatively boundless freedom of action and conduct. It had been worth while to grow up. The average child of to-day had the same amusements as the average adult, and relatively greater freedom. Personally or vicariously—through the cinema—it experienced practically all that would be possible for it, and adulthood had few additional pleasures to offer in compensation for its greater responsibility. There was little in the conditions of modern industry to capture the imagination of a boy. Children who at this period became problem children nearly all suffered from atrophy of the sense of adventure, a sense which could be kept alive only if the child's lines of interest were kept clear.

INDUSTRIAL HEALTH EDUCATION SOCIETY.

A LUNCHEON was given by Lord Melchett at the Carlton Hotel on Thursday, Oct. 31st, to afford an opportunity to those interested in the objects of this Society to meet and to hear an exposition of the aims and position of the movement. Lord Melchett, who was supported by Sir Humphry Rolleston (hon. president of the Society), Lord Dawson of Penn, Sir John Rose Bradford, and Sir Arbuthnot Lane, in a brief speech welcomed a representative group of industrial employers and medical men. He pointed out that splendid work had already been done among industrial populations by the medical profession, but that much remained to be done owing to the fundamental ignorance of the bulk of the operatives and of no inconsiderable number of their employers. In regard to pit-head baths, he said, England, Wales, and Scotland were far behind the Continent and the United States, in which latter country the workman, after hours, was never seen in his work-soiled clothes, having had opportunity for washing and changing.

Sir William Milligan then described the great services rendered to public health by the Industrial Health Society, under whose auspices a number of indefatigable lecturers had submitted to varied and interested audiences the methods for the prevention and remedy of accidents incidental to their employment. The Society was formed in 1925, during which year 118 health-talks were delivered; in the following year the number increased to nearly 200, in 1927 to nearly 300, in 1928 to practically 400, while in the first three-quarters of the current year more than that number had already been given. He concluded by pointing out that the pecuniary resources of the Society had been strained to the utmost by the work which they had already undertaken and this at the time when openings for the development of that work were obvious. All the organisations of operatives in England, Wales, and Scotland had shown willingness to coöperate, recognising the obvious importance of the movement. He quoted figures to show that in 1928 the work of over half a million weeks was lost in England and Wales through sickness and invalidity, while the approved societies during that period paid out £15,000,000 in sickness and disablement benefits. While the Society, he said, had as yet made no appeal to the employers of labour for assistance, the time had come when it must be pointed out that more funds were required if the work was to go on, and he hoped that the whole movement would receive sympathetic consideration from those around him who directed important industrial businesses, and also from insurance companies.

Mr. Ben Tillett, M.P., proposed Lord Melchett's health in eloquent terms from personal knowledge of the chairman's qualities of leadership and generosity. He went on to point out that education on health matters in connexion with particular industries should be directed as much to the employers as to the employed, as the last thing the average employer thought about was the sanitary convenience and the necessities of human workers. He spoke as a non-party man, and with a real desire to see among the British an appreciation of the factor of efficiency in the matter of health. He held that the employing class had not considered with proper care the working of the finest machine they possessed—namely, that made by God Almighty.

Lord Melchett briefly replied.

GENERAL MEDICAL COUNCIL.

ELECTION OF TWO DIRECT REPRESENTATIVES FOR ENGLAND AND WALES.

Two names were selected last July by English and Welsh deputies at the annual meeting of the British Medical Association for nomination on behalf of the Association as Direct Representatives of the registered medical practitioners of England and Wales on the General Medical Council. These were Dr. H. B. Brackenbury, who has already served on the Council, and Mr. N. Bishop Harman. On their behalf the following election address has been circulated:—

> We offer ourselves as candidates for election to the General Medical Council as direct representatives of the registered medical practitioners of England and Wales. One of us has been such a representative for the past five years and, as a member of the Education and Public Health Committees of the Council, has taken an intimate part in that review of medical education and of the needs of the public health service in which the Council has recently been engaged and which is not yet concluded.

We regard it as of great importance that advantage should be taken of the method of direct representation to secure the presence on the *Council of additional* members who have considerable experience of private practice (including special as well as general and insurance practice) in order that the conditions of such practice may be fully weighed in connexion with any disciplinary proceedings. In this regard, one of us has been in active general practice and insurance practice for many years, while the other, in addition to a long experience in private practice and as a member of a hospital staff, has held for a considerable period an important office in the School Medical Service of the London County Council. Both of us have been members of the Hospitals Committee of the British Medical Association and of the Insurance Acts Committee for a number of years, and so are familiar with those hospital problems which are so important at the present time and with the special conditions attached to insurance practice. Each of us has been, and is, in a position which brings him into contact with all varieties of medical practice and enables him to familiarise himself with general professional opinion; and we may claim in this way to be able to appreciate and to voice that opinion to an altogether exceptional degree.

In connexion with medical education it is important, we think, that the point of view of those who are the taught and the examined should be prominently considered along with the point of view of the teacher and examiner. The conditions of actual practice, general or special, are not always as prominent in the mind of the teacher as they well might be. The position of special branches of practice should not be lost sight of in prescribing the medical curriculum or in regulating training and examination—whether such special practice be followed exclusively or cultivated in association with a more general practice, especially perhaps in relation to extended or additional insurance benefits and to the clinical services of local authorities. In the administrative and legislative aspects of these matters as well as in their educational aspects, the position of the General Medical Council is one of increasing influence and importance. In our opinion such influence should be exercised in the direction of maintaining the best traditions and methods of private practice, and we claim that our familiarity with such administration and its problems will be a valuable qualification for such service as we may be able to render should our candidature be successful.

If opportunity should arise we should strongly advocate and support an increase in the number of direct representatives on the Council.

H. B. BRACKENBURY, LL.D., M.R.C.S., L.R.C.P.
N. BISHOP HARMAN, M.A., M.B., F.R.C.S.

As an independent candidate for one of the two vacant places, Dr. Arthur Haydon offers himself for election. His address is as follows:—

I offer myself as a candidate for election to the General Medical Council as a direct representative of the registered medical practitioners of England and Wales.

In 1911 I was a candidate for election to the General Medical Council, while in practice at Henrietta-street, W., and was fortunate in receiving 1000 votes, though I was not elected on that occasion. As a proof of my interest in education, I may say that I have been president and secretary of the Brussels University Medical Graduates Association for 21 years, during which time, I was in constant communication with candidates for the scientific degree all over the world. I have travelled, both professionally and otherwise, more than 65,000 miles in many parts of the world, and have studied medical practice in all climates and under all conditions. If within the province of the General Medical Council, taking the excellent example from the Dominions, I would recommend that a Bill might be promoted before Parliament to secure the complete abolition of unqualified practice, which is undermining legitimate medical practice, and making it nearly impossible for newcomers into the profession to make a living. If my candidature should be successful, it will be my endeavour to adopt a progressive policy, and to urge revision of the formula whereby medical practitioners are penalised for so-called infamous conduct in a professional sense, and perhaps to be able to modify any undue severity on the part of the General Medical Council in a disciplinary sentence on medical practitioners for trivial offences. I am not in favour of the nationalisation of hospitals. I should also be strongly in favour of an increase in the number of direct representatives on the Council, as I consider the number at present to be quite inadequate.

ARTHUR HAYDON, M.D., M.R.C.S., F.R.G.S.

CLATTERBRIDGE ISOLATION HOSPITAL.—A new wing of this hospital, erected under the auspices of the Wirral (Cheshire) Joint Hospital Board, has recently been opened. It contains a large ward for women and children, a smaller one for men, and two private wards, with a total of 22 beds.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1928 statistics of four cathedral cities, three boroughs, and one urban district:—

Name of district and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and neonatal mortality.	Young child (1–5 yr.) mortality.	Maternal mortality from childbirth.
Ealing, B. .. (98,660)	14·9	10·5	0·77	1·49	1·3	1·9	41/22	—	5·5
York, C. .. (85,410)	18·1	11·7	0·99	1·27	1·7	2·2	59/28	23	4·4
Lincoln, C. .. (65,550)	14·8	12·3	1·11	1·50	1·9	2·3	58/33	23	3·1
Carlisle, C. .. (56,380)	19·6	13·0	1·08	1·48	1·6	2·0	73/46	22	0·0
Chester, C. .. (40,830)	17·0	11·2	0·95	1·44	2·0	1·9	50/24	34	7·1
Shrewsbury, B. (31,870)	16·9	12·3	0·78	1·50	1·5	3·0	56/32	22	3·6
Eccles, B. .. (45,200)	16·4	11·0	0·68	1·42	1·8	1·6	66/28	24	5·4
Billingham, U.D. (11,690)	24·1	10·7	0·68	0·86	2·8	1·2	89/—	25	10·6

The proportions of stillbirths notified per 100 live births, were: York, 2·6; Lincoln, 5·5; Carlisle, 4·8; Chester, 5·0; and Shrewsbury, 2·9.

Ealing.

Dr. Thomas Orr gives the population as 100,250 at the end of the year, after the inclusion of Northolt, when the area of the borough became 9135 acres and the density 11 persons per acre. The extension has brought many problems. The Greenford and Northolt wards get their water from the Rickmansworth and Uxbridge Company, and many new mains are needed. The rest of the area is supplied by the Metropolitan Water Board. The stream through Greenford, which caused a nuisance, is now reasonably pure. Many cesspools in the added area need abolition, involving the laying of new sewers. Of the five sewage works, two are efficient. A sludge-pressing plant is being installed at Hanwell, and chlorine treatment has kept in abeyance the nuisance from the Greenford works. Greenford and Northolt are scavenged by private contract, and are to be brought into the general scheme. New maternity and child welfare centres are being provided for the added area, and the latest school is to be of the Derbyshire type, a true open-air school, in which the class-rooms can be kept open in winter and summer; yet sheltered from the wind and adequately warmed.

Ealing applied to the Middlesex County Council for delegated powers for the supervision of maternity and nursing homes, but was refused, and the application is to be reconsidered by the Ministry under the Local Government Act, 1929. Successful proceedings were taken against a retail milk purveyor for trading without being registered, against a milk man for filling bottles not in registered premises, and against a retail milk purveyor for selling designated milk without a licence. Many dairy premises have been improved, and an incentive to this result has been provided by the greater interest taken by the public in the source of their milk-supply. Of 12 samples of ordinary milk, three were found to be tuberculous, and in two of the three cases the Middlesex County Council was successful in finding and condemning the offending cow. There were 68 notifications of diphtheria, with a 10 per cent. case fatality, and Dr. Orr comments on the delay in using antitoxin. There were 12 cases of typhoid fever, with four deaths, and 14 cases of puerperal fever and pyrexia, with two deaths. Dr. Edna Langston has been appointed to investigate maternal deaths from childbirth as desired by the Ministry. The percentage of school "leavers" with sound teeth has increased from about 30 in 1915–16 to 67 in 1927–28. By routine and special inspections, 27 children with organic, and 87 with functional heart disease were discovered, and will be specially supervised.

York.

Dr. P. R. McNaught says York is not described as an industrial town, but that in addition to being an ecclesiastical and military centre, it is an important railway centre, employs about 10 per cent. of those engaged in the cocoa, chocolate, and confectionery industry, and has beet-sugar works. None of the industries is thought to be harmful to health. There are many voluntary health societies. The diocesan home for unmarried mothers admitted 28 expectant mothers, and 27 mothers with infants, and receives a grant of £100 from the corporation. In the case of the seven maternal deaths, investigation revealed that delivery was spontaneous in four cases and by Cæsarean section in one, and that in two cases delivery did not take place, one dying from cardiac failure and the other from hæmorrhage and placenta prævia. Of 45 neonatal deaths investigated 32 were attributed to prematurity, 2 to syphilis, and 3 were "born before arrival." There appears to be no orthopædic scheme, but arrangements have been made for the admission of crippled children to the Yorkshire hospital at Kirbymoorside. There is a shortage of houses, and 1600 applicants are on the waiting-list for houses on the Tang Hall estate, where the corporation have built 1272 houses, and had 210 more in course of erection at the end of the year. One unhealthy area with a population of 805 is being dealt with, and about 750 houses are waiting for demolition or renovation when the shortage is relieved. The York House Improvement Society has been formed for the purpose of purchasing houses in need of repair, renovating them, and letting them at weekly rentals of from 3*s.* 6*d.* to 6*s.* 6*d.*, with collection and management on Octavia Hill lines. Another voluntary committee, "Tuberculosis Crusade," in its 1928 report (included), considers the housing problem the greatest barrier to their progress, and that for the great mass of slum-dwellers post-war Housing Acts have accomplished nothing. They favour the "children's rental allowance system" recommended by Mr. E. D. Simon. Out of 57 samples of milk examined, five were found to contain tubercle bacilli.

Lincoln.

Dr. D. C. Lamont, who took over the duties on June 18th, states that the small-pox epidemic, which began in November, 1927, and accounted for 71 cases in that year continued until June, 1928, causing 107 additional cases. There were no deaths. The notifications of diphtheria, 183, were higher than in any of the previous 10 years. There were seven deaths, and Dr. Lamont, in recommending an immunisation scheme, mentions that the Paris Education Authority has taken this up energetically, with the result that 47,000 children were inoculated there in the second half of 1928. The new isolation block of 10 beds, built on the cubicle system, has proved a success, and at one time housed seven different diseases. The orthopædic scheme of the Education Committee began in June, 1928, and was extended at the end of the year to include children under five years and tuberculous cripples of any age. The total births numbered 980. The antenatal clinic was attended by 402 expectant mothers, of whom 227 had booked for the maternity home and 175 had engaged a municipal district midwife. A fourth municipal midwife is to be appointed. There are only two midwives in private practice in Lincoln, one of whom is a "bona fide," and the other only acts as a maternity nurse. Systematic antenatal supervision by the municipal midwives has, to a large extent, abolished the unwillingness of mothers to undergo examination during pregnancy. A nuisance has arisen owing to the discharge of excreta from house-boats into the rivers and dykes, the current being very sluggish, and endeavours are being made to combat it. A voluntary slum clearance committee has been formed with the object of providing low-rented houses for necessitous tenants. The immediate aim is to subsidise 100 houses with £70 each, and to let them at 6*s.* 6*d.* per week, inclusive of rates. The inclusive rental of municipal houses is 15*s.* 4½*d.* for the parlour, and 13*s.* 2*d.* for the non-parlour type.

Carlisle.

Dr. Joseph Beard reports that 29 samples of fresh cow's milk were examined for tubercle, that two were found positive, and that as a result the veterinary inspector of the Cumberland County Council eliminated two milch cows from herds in his area. The corporation maintains a well-equipped slaughter-house. Meat stalls are only permitted in the covered public market, and all butchers' shops are fitted with windows. Dr. Beard complains that, in too many instances, patients are not notified as suffering from tuberculosis of the lungs until, frequently as the result of repeated bacteriological examinations, tubercle bacilli are found in the sputum. The births numbered 1100, and 174 confinements took place in the municipal maternity home. This home has now trained 24 pupil midwives, and all of them passed the C.M.B. examination at the first attempt. The antenatal clinic was attended by 201 expectant mothers. Of the 122 infant deaths, 51 occurred before the age of one month, 42 before the age of one week, and 29 before the end of one day. Dr. Beard expresses his disappointment at this result, seeing that in 1927 Carlisle won third prize among the towns with populations from 50,000 to 100,000 in a competition as to the greatest reduction achieved in neonatal mortality. Thus, in 1927 6 children died in the first day, 14 in the first week, and 25 in the first month, whilst the figures for 1928 were 29, 42, and 51 respectively. For a long time statistics have been kept as to the aid to survival of breast-feeding as compared with bottle-feeding. A table shows that in 1928 the mortality-rate per 1000 of 754 breast-fed infants was 25, and of 195 bottle-fed infants was 50, but also gives the curious result that the mortality-rate of 123 infants, partly breast- and partly bottle-fed, was 81. The lessening mortality among bottle-fed infants yearly indicates increased skill on the part of the mothers. Forty-two debilitated infants, who were practically unable to be fed (presumably those who died in the first week), were not put in any of the classes mentioned. The clearing of one slum area and the rehousing of the tenants is in progress. Forty-one of the evicted tenants were induced to take new corporation houses, while 13 others secured better houses by conceding their claim to a new house to other householders.

Chester.

Dr. D. Rennet reports that the maternity hospital
is a voluntary institution, and that the [illegible]
paid for 10 of the 120 city patients admitted to [illegible]
during the year. The hospital also admits pati[illegible]
from outside the [illegible] an extensive ext[illegible]
department [illegible] clinic, which
attended in 1[illegible] [illegible]ant mothers.

the un[illegible] and

improvement is claimed in debility and early rickets, considerable benefit in some forms of non-pulmonary tuberculosis, but only qualified improvement in lupus.

The new municipal houses numbered 141 and private enterprise completed 35. Closing orders were made for 28 houses, so that the net gain of new houses was 148. The dairy herds are inspected by the veterinary officer but only twice a year. As the result of 17 biological examinations, one tuberculous cow was found and another was discovered by microscopical examination of the milk. The public analyst reports that the milk fat in eight samples of ice-cream examined varied from 1 per cent. to 14 per cent., and suggests a standard of 12 per cent. as reasonable.

Shrewsbury.

Dr. A. D. Symons expresses his emphatic approval of the new health department premises. He gives an interesting quotation from the report of 1878, in which the medical officer expresses the opinion that with its advantages Shrewsbury might attain a rate of 16 per thousand, but thought an average a little over 17 more within the bounds of probability. In 1878 there were 250 cases of typhoid fever with 20 deaths, and the then medical officer was right in believing this "to be absolutely and completely removable." Dr. Symons thinks his predecessor would be surprised to learn that in 1928 the birth-rate was 16·9, the death-rate 12·3, and the infant mortality-rate 56, as compared with a birth-rate of 32·2, a death-rate of 22·2, and an infant mortality-rate of 140, in the year of which he wrote. The infant mortality-rate of 1928 was increased in comparison with the previous year (43) largely owing to an unusual number of twin births. There were 13 sets of twins amongst the 552 births. In the five preceding years the sets of twins numbered 4, 6, 7, 2, and 4, respectively, and of the 31 infant deaths in 1928, 8 were those of twin babies. Dr. Symons, after investigation, divides the 31 infant deaths into 8 unpreventable, 13 possibly preventable, and 10 preventable, and sees no reason why the rate of Shrewsbury should not be between 20 and 30, even with our present knowledge. The dual system of water-supply, consisting of drinking water supplied by means of self-closing water pillars in the streets and treated river water laid on in the houses for domestic purposes, has given no anxiety as regards quantity or quality during the year. Hitherto, in the housing schemes preference has been given to tenants (*a*) who had children, or (*b*) who could afford the rent. The majority of those selected respond to the uplift, but there are many who fail to carry out their agreement, and who show that they are incapable of, or indifferent to, cleanliness and better habits. Dr. Symons thinks it is unfair to rehouse bad tenants next door to good ones, and his remedy is a separate colony, managed on Octavia Hill lines, from which families who showed a desire to rise could be ultimately transferred to a different housing estate.

Eccles.

Dr. J. E. Spence reports that measles and whooping-cough were both epidemic during the year. During the past 15 years the mortality from these two diseases has been more than three times as great as that from scarlet fever and diphtheria combined. Measles has been notifiable in Eccles since 1920 and whooping-cough since 1924, so that it is now possible to give figures for the case fatality of these diseases. During the first year of life 1 patient out of every 21 dies from whooping-cough and 1 out of every 31 from measles. During the second year 1 out of 36 dies from whooping-cough and 1 out of 35 from measles. During the third year 1 out of 43 dies from whooping-cough and 1 out of 38 from measles. After three years old the fatality of these diseases becomes almost negligible, as at all ages over three 1 out of 880 patients dies from whooping-cough and 1 out of 396 from measles. If these facts could be brought home to parents, says Dr. Spence, the fatalistic attitude might be abandoned, and a greater effort made to protect the younger children from infection. Out of 12 samples of milk examined two were found to be tuberculous. The first came from a borough farm. All the cows were examined by the veterinary surgeon. A sample of milk was taken from a suspicious cow, and the remainder were divided into four groups of five for sampling purposes. The separate sample proved negative. One of the four groups gave a positive result, but a cow from this group was sold shortly after the original sample was taken, and the milk from the remaining four proved negative. Doubtless the cow sold was the offender. The first sample was taken on August 14th, and on Oct. 24th six pigs from this dairy farm which had been fed on skimmed milk were found at one of the slaughter-houses to have tuberculosis of the mesenteric glands and liver. Dr. Spence cites this as an effective demonstration of the risk which young children run. After a demonstration of the use of a solid smokeless fuel in the public health offices, the trader, who held the local agency, found that the demand exceeded the supply. This fuel is also being tested for the heating of the public central library.

Billingham.

Dr. T. J. Kirk submits the report for this rapidly growing industrial town, which is being tacked on to the Durham village of Billingham and the older district of Port Clarence. The new houses in 1928 numbered 502. The staff of district nurses has been increased and the two child welfare clinics are well attended. Other problems are being energetically tackled. For example, the privies at Port Clarence are being converted to w.c.'s, the collection of refuse and tipping methods are being reorganised, and the "Bendy," a large sheet of filthy stagnant water, has been abolished by drainage and filling in with clean earth. The three butchers have adopted the Cash captive bolt pistol. The main problem of the district, however, is atmospheric pollution, rather than smoke abatement, owing to the emission of dust and grit by three of the most important works in the area. Synthetic Ammonia and Nitrates, Ltd., cause a serious nuisance by the emission of fine grit and dust from their method of steam raising by pulverised coal. It is hoped that the fitting of water sprays into the chimney stacks may be an effective remedy. Casebourne's Cement Co., Ltd., give off a fine yellowish-grey powder, which, under certain weather conditions, covers the whole of the property within a considerable area. An experimental dust arrester proved a failure, but further experiments are in progress. The nuisance caused by the North Tees Power Co. is a much smaller evil and more local, and affects fewer dwelling-houses. In this case steam is raised on the chain grate system, and grit is only emitted at intervals, when soot-blowing is in operation. One dust arrester has been fixed by this company, and it is expected that a similar apparatus will be fixed to each chimney stack. Finally, it can be said that all the firms mentioned are making every effort to find a complete solution to their respective problems.

MENTAL HOSPITAL REPORTS.

THERE were 900 patients in the *Dorset Mental Hospital* on Dec. 31st, 1928, an increase of 20 during the year, and there is still danger of overcrowding. A scheme is under consideration to hand over the north male block to the female side, and to build a new dormitory on to the old recreation hall to provide additional accommodation for the men. The recovery-rate was 39·56 per cent. and the death-rate 5·68 per cent. Apart from six patients suffering from phthisis, and six women known to be carriers of typhoid, the patients had extremely good health and suffered from no epidemics. A dentist visited fortnightly and saw 372 patients. A dormitory is to be enlarged in order to free a room for handicrafts, and an instructress from the Occupation Therapy Association has initiated the work by giving a course to patients and staff. Two male wards are administered on the open-door system, and 84 men and three women are allowed on parole beyond the estate. The laboratory is well equipped, and research is carried on as well as extensive routine investigations. The number of examinations at the bedside and in the laboratory reached 2425 during the year. The discovery of a hydatid cyst of the liver infected with the typhoid bacillus led to a routine search for typhoid carriers by the method of Wilson and Clair. The Meinicke micro-reaction has been carried out on all new admissions, but has not been found to parallel the Wassermann reaction closely enough for it to be relied upon. A leucocyte study is being continued, and the importance of frequent systematic leucocyte examination in mental disease is emphasised in the report. Buscaino's black reaction is done as a routine, and its relationship to Scheiner's reaction is to be worked out. The colloidal reaction of Takata-Ara is being investigated. Patients with general paralysis are treated with tryparsamide; three out of nine developed a negative or weakly positive Wassermann reaction. The out-patient clinic is held weekly at the Dorset County Hospital. Five nurses and two attendants passed the final R.M.P.A. examination, so that about one-third of the nursing staff are now certificated or registered.

The *City of Leicester Mental Hospital* at *West Humberstone* had 955 patients on its books on March 31st last. The recovery-rate was 53·64 per cent. and the death-rate 5·88 per cent. Cause of death was verified by autopsy in 92 per cent. of cases. A systematic investigation revealed two typhoid carriers, one of which has cleared up under treatment, while the other remains a source of infection. General paralytics are being received from a neighbouring mental hospital for malarial treatment, and ten cases have had pyrexial attacks induced during the year. There was one death unassociated with malaria, three patients were slightly improved, and three were discharged. Leave of absence was granted 2448 times to men, and 1250 times to women during the year, and the number of week-ends allowed has increased. Of the male patients 53 per cent., and of the female 37 per cent. are on full or limited parole; 14 men on parole escaped during the year. Useful employment was found for 77 per cent. of the patients. Cinematograph entertainments are given regularly in the hospital, and small parties of women go regularly to local cinemas and for motor drives. The routine work of the laboratory continues to increase. A small outbreak and a couple of isolated cases of Sonne's dysentery occurred during the year, but responded readily to treatment. The visiting dentist inspected all new cases and 91 old inmates, and performed 339 operations. A new nurses' home is proposed, and the old superintendent's house has been adapted as a unit for 332 women patients. A Vermes photometer has been installed. Two nurses obtained the qualifications of the General Nursing Council.

The *Stafford Mental Hospital* had 1022 patients in residence on Dec. 31st, 1928, an increase of 19, despite the removal of 30 men to the East Riding Mental Hospital. There was a deficiency of 78 beds, although the isolation hospital, with 20 beds, is still occupied by male convalescents. The new reception hospital, now being built, will relieve but will not cure the situation. The recovery-rate was 25·60 per cent. and the death-rate 6·80 per cent. Autopsies were held in every case where permission was given. Sixty-three patients were allowed out on trial before discharge, but only one was given money allowance. Two men have parole beyond the estate, and 83 men and two women are free within the grounds. One ward on each side and the male convalescent block are administered on the open-door principle. There are 11 male and eight female patients suffering from tuberculosis, but there has been no epidemic disease. Forty-eight attendants and eight nurses are certificated or registered. At *Burntwood*, the second of the three Staffordshire mental hospitals, there were 924 patients on Dec. 31st, 1928, a decrease of 19, which is almost entirely due to transfers of men under contract. On the female side the hospital is overcrowded, and the vacant male beds are rapidly being filled. The isolation block is still occupied by male patients, and isolation has to be provided in the main building. The recovery-rate was 28·2 per cent., the rather low figure being the result of a serious outbreak of Flexner dysentery which accounted for 22 deaths. At the time the sewers of the sanitary spurs at the back of the female ward were being excavated for replacement, and infection was probably carried on the boots of men engaged on the work and women coming from the laundry. There was also an outbreak of typhoid fever on the female side, and six patients died. The South Staffordshire Company's water was being supplied to all parts of the hospital except the female division, which was served by private well-water. This water was found to have a high *Bacillus coli* count. The connexion of the female wards with the company's water-supply was carried out as rapidly as possible, and the well was reconditioned. Vaccine was given to as many contacts as possible, and there was no recurrence of either infection. There were 81 cases of influenza with one death. Four cases of general paralysis were treated with malaria; two improved, and two—both older cases—died. Of the patients discharged during the year, 49, or 65 per cent., were given preliminary periods of trial, 20 of them with money allowances. A thermal bath has been provided in both male and female divisions, and electric light has been extended in the male wards. Since the appointment of a cowman the milk-supply from the farm has increased by 3727 gallons during the last year. Condensed milk is not now used, but butter is only given to undernourished patients. An ultra-violet ray apparatus has been installed, and two female solaria have been fitted with "Vita-glass." Four attendants and one nurse passed their final examination. The third Staffordshire hospital at *Cheddleton* had 1107 patients in residence on Dec. 31st, 1928, a reduction of 27, due to boarding out under contract. There are 20 more women than the statutory number, but 21 male vacancies. Patients boarded out included many of the best workers, so that Cheddleton work has suffered. The medical superintendent points out that the provision of colonies for chronic cases, and the early discharge of convalescents, will materially increase the cost of running a mental hospital. General paralysis was treated by malaria, and four cases were discharged during the year. Five patients were known to be suffering from tuberculosis on admission. There were 38 cases of dysentery, three more than last year, but fewer of them were unexplained. Only three cases of encephalitis lethargica were admitted during 1928, bringing the total in residence to 26. Ten cases were treated, without benefit, with malarial blood, and ten were given tincture of stramonium, which gave temporary improvement in all cases. A ward has been arranged for training lads who have got beyond the control of nurses. They are taught tailoring, cobbling, gardening, drilling, handicrafts, and games, and the experiment seems likely to be very successful. The orthopædic department has been very successful in improving the deformities and habits of low-grade congenital cases. The usual statistics are not supplied in this report. In March, 1928, the visiting commissioners found 56 men and 36 women on parole beyond the estate, 30 men and four women on more limited parole, and three wards administered on the open-door system. They note that 20 per cent. of the female and 60 per cent. of the male nurses are certificated or registered; an orthopædic sister attends twice a week, an electrotherapeutic sister attends regularly, and a schoolmistress teaches the children for four hours daily.

At *Winson Green* there were 812 patients on Dec. 31st, 1928. The recovery-rate was 45·2 per cent., and 44 of the 83 patients discharged had a month's preliminary trial, 33 of them with financial assistance. The death-rate was 7·7 per cent., and post-mortem examinations were made in 95 per cent. The general health was good; there was no infectious disease, except two cases of erysipelas and three of tuberculosis. The treatment of focal sepsis gave most encouraging results. Protein therapy was found beneficial, especially after operation had converted a closed sepsis into an open one. Eight male and two female general paralytics were treated by induced malaria. One man and one woman were discharged apparently in normal health, and one man died. Six dementia præcox patients were inoculated without benefit. Weekly entertainments are given, and every ward has a gramophone, and is being fitted with a loud speaker. Both male and female reception wards have been fitted with verandahs. The R.M.P.A certificate is now held by 78·1 per cent. of the attendants and 41 per cent. of the nurses.

At *Rubery Hill and Hollymoor* there were 1800 patients on Dec. 31st, 1928. The recovery-rate was 42·2 per cent. and the death-rate 6·44 per cent. Autopsies were carried out in 59·2 per cent. of the cases. General paralysis was treated by induced malaria, typhoid-paratyphoid vaccine, and chemotherapy, including tryparsamide, and three cases have been discharged recovered. Nasal sinusitis was suspected in 151 cases, and proved in 116—i.e., 33 per cent. of the total admissions. A very large number of other causes of toxæmia were suspected, and the principal aim of treatment here is to combat this toxæmia, generally without any coöperation from the patient. Only three cases of tuberculosis were recorded at the end of the year, and there was no other infectious disease. Cinematograph entertainments were given regularly and much appreciated. The dairy herd was twice tested for tuberculosis. During the year 18 attendants and 17 nurses obtained their R.M.P.A. certificate, bringing the totals to 93 and 61 respectively, while 14 attendants and 26 nurses were registered by the General Nursing Council.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 26TH, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 131 (last week 154); scarlet fever, 3504; diphtheria, 1709; enteric fever, 141 (last week 140); pneumonia, 1008; puerperal fever, 58; puerperal pyrexia, 94; cerebro-spinal fever, 11; acute poliomyelitis, 30; acute polio-encephalitis, 2; encephalitis lethargica, 11; dysentery, 17; ophthalmia neonatorum, 104. No case of cholera, plague, or typhus fever was notified during the week.

Of the notifications of enteric fever, 41 were received from the County of London—namely, one each from Camberwell, Hammersmith, Islington, St. Marylebone, St. Pancras and Wandsworth, and 35 from Lewisham. Of the 14 notifications from Kent, 8 came from Beckenham and 2 from Penge.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Oct. 29th–30th was as follows:—Small-pox, 172 under treatment, 12 under observation (last week 163 and 9 respectively); scarlet fever, 2657; diphtheria, 2364; enteric fever, 90 (last week 60); measles, 231; whooping-cough, 125; puerperal fever, 22 (plus 12 babies); encephalitis lethargica, 125; poliomyelitis, 9; "other diseases," 19. At St. Margaret's Hospital there were 16 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 6 (3) from enteric fever, 14 (4) from measles, 11 (0) from scarlet fever, 12 (2) from whooping-cough, 51 (11) from diphtheria, 102 (19) from diarrhœa and enteritis under two years, and 56 (15) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London were reported from Liverpool, Darlington, and Merthyr Tydfil. In spite of the decline of diarrhœa generally Liverpool reported 22 fatal cases, Birmingham 8, and West Ham 5.

The number of stillbirths notified during the week was 264 (corresponding to a rate of 41 per 1000 births) including 45 in London.

THE HANDLING AND STORING OF CELLULOID X RAY FILMS.

THE British X Ray and Radium Protection Committee have now amplified their preliminary suggestions for the handling and storing of celluloid X ray films, which were made in our correspondence columns after the Cleveland disaster.[1] They point out that the X ray films of cellulose nitrate in common use burn with rapidity and violence when ignited. The burning of cellulose nitrate in bulk is well-nigh explosive in character. In addition, large quantities of carbon monoxide and brown fumes of oxide of nitrogen may be generated, both of which are highly toxic, and indeed led to a heavy death-roll in the Cleveland clinic fire. Carbon monoxide is itself inflammable and when mixed with air may give rise to an explosion; celluloid will burn in the absence of air.

Recommendations.

Regulations on the handling and storing of celluloid have been issued by the Home Office, local authorities, and others. The Protection Committee make the following recommendations.

X Ray Rooms.

In all rooms where X ray films are handled *and stored naked lights and open fires* should be prohibited. Smoking should be prohibited in or near film cabinets or film stores. Films should not be placed near steam pipes, radiators or the like. A ready supply of fire extinguishers together with buckets of water and sand should be available. The best means of extinguishing burning celluloid appears to be by the application of water.

Electric light installations should be of a permanent character. Electric light bulbs in or near film stores or cabinets should be enclosed in strong glass globes.

Generous ventilation should be provided in X ray rooms. As recommended in paragraph 5 of the International Protection Recommendations, the plan of an independent exhaust fan in each room is to be preferred to a duct system common to a number of rooms. Doors should be arranged to open outwards, particularly from film-drying rooms and dark rooms.

The *stock of X ray films*, whether unexposed or developed, should be kept down to the minimum. The stock of film records should be subjected to periodical drastic weeding out. Discarded films should be at once deposited in strong fire-proof metal containers with self-closing lids and destroyed at frequent intervals. They should not be placed in general refuse bins, or burnt in a closed vessel.

Stocks of unexposed films for immediate use or current files of developed films should be stored in cool and dry lock-up thermally insulated metal or hard wood cabinets. Such a stock should not exceed a total of about 50 lb.—i.e., about 1000 12 in. by 10 in. films—distributed among several cabinets. Cabinets for unexposed films should be lead lined. *Developed films*, which are temporarily taken into hospital wards or theatres for the convenience of the medical staff, should not be left lying about in table drawers or cupboards, but should be kept in suitable metal containers. Such films should be returned to the X ray department as soon as possible.

Film Stores.

Stocks of film exceeding about 50 lb. should not be stored in the X ray department, but in a special dry, cool, and well-ventilated room reserved exclusively for the purpose. The main requirements of such a room are as follows:

(*a*) The situation of the film store should not be such as to endanger the means of escape from any part of a building. The store should not be in the proximity of a lift-shaft or staircase-well, or near an intake or outlet of a general duct-ventilating system. In no circumstances should the store communicate with a general duct-ventilating system. The store should preferably be an isolated single-storey building with independent access. Failing that, it may be placed on the roof of a building or, if that is not feasible, in one of the higher storeys in as isolated a position as possible.

(*b*) The walls, floor and ceiling of the store room should be fireproof and of robust construction. The door should be fireproof and of a self-closing, closely fitting type. If the store room forms part of a main building, a useful further precaution is a fireproof vestibule with a second fireproof door.

---

[1] THE LANCET, 1929, i., 1223.

(*e*) The store should be provided with a direct vent to the outer air, preferably on the side remote from the most adjacent building. Such a vent should not normally be less than a square foot in effective area, a figure which may require to be exceeded for large stores. The vent may be protected against weather, &c., by thin unwired glass or other equally frail device.

(*d*) A film store may well be equipped with steel cabinets. If the store is designed to carry unusually large stocks of films (exceeding, say, 1 ton), it should be divided into completely isolated fireproof compartments each with its own vent and fireproof door.

(*e*) The temperature of the store should be maintained at a moderate figure. If the roof is exposed to the sun, suitable thermal lagging may be necessary in hot climates. It seems certain that good quality celluloid does not ignite spontaneously at any temperature attained under ordinary room conditions.

(*f*) The store should be equipped with an automatic water sprinkler device.

(*g*) If windows are provided in a film store, they are best situated in a north wall, though other considerations may be more important. Any windows immediately above the windows or vent of the store room should be provided with wired glass.

The committee, of whom Sir Humphry Rolleston is president, record their view that the production and use in this country of satisfactory "safety" X ray films should be encouraged.

AUSTRALIA.

(From our own Correspondent.)

Australasian Medical Congress.

The third session of the Australasian Medical Congress (British Medical Association) was held in Sydney at the beginning of September under the presidency of Dr. G. H. Abbott. Over 900 people attended, including about 350 visitors from other States and from overseas, including Sir Ewen Maclean, Sir Louis Barnett, Dame Janet Campbell, and Prof. Hugh MacLean. The inaugural meeting was held at the Town Hall, Sydney, when Lord Stonehaven, Governor-General of the Commonwealth, opened the proceedings. At the first session in the Great Hall of the University speakers from each of the States and from New Zealand gave an account of

What is Being Done in Australasia Towards Cancer Research.

In the course of the discussion Dr. F. P. Sandes, Director of Treatment in the Cancer Research Department of Sydney University, said that the University had just completed a radium emanation station for the assistance of practitioners in outlying places. He urged that the treatment of cancer by X rays and radium should be vigorously encouraged, and pointed out that the greatest difficulty lay not in getting money but in finding men with sufficient originality of mind and method to take up cancer research. Under present conditions, the students who were prepared to devote their talents and their life to research were offered less than a tradesman's income. Dr. Peter MacCallum, professor of pathology in Melbourne University, said that the statistical and experimental research on the relationship between tuberculosis and cancer in mice, which was begun by Dr. Thomas Cherry some three years ago at the Walter and Eliza Hall Institute, had already given remarkable results. He described the work now being done at this institute and at Melbourne Hospital, the Baker Institute, and the Alfred Hospital. At the Commonwealth laboratories, said Prof. MacCallum, Dr. Hirst and Miss Doery were carrying on research on the nature of metabolism of cancerous growths and had so far confirmed the work of Warburg. Dr. E. Sandford Jackson reported that lead treatment in various forms had been given a considerable trial in a number of cases in Queensland, but had now fallen into disuse. Treatment by radium was making progress, and since the Commonwealth radium had become available in Queensland hospitals radium therapy had overshadowed every other kind of treatment. The present tendency, he said, seemed to be to put the radium under the control of small coteries of medical men, and this system was to be deplored. It was important that a whole-time paid director should be appointed to each State and that there should be an attempt in research into the causation of cancer under Australian conditions. Dr. A. A. Lendon stated that a deep X ray therapy plant would shortly be installed at the Adelaide Hospital. At present this form of treatment was being carried out privately on hospital cases with encouraging results. The organisation of the radium clinic at Adelaide was not yet complete. Dr. Bronhall in a communication described the position in Western Australia. As there was at present no medical school in Perth very little experimental work was being carried out except privately, but the treatment by radium was now being freely used. The Federal Government had recently offered the sum of £5000 to establish a cancer fund, and £18,000 had already been raised. It was intended to build a department at the Perth Hospital which would include X ray rooms and deep ray treatment rooms. Sir Louis Barnett said that in New Zealand investigations of cancer, through the hospitals, had been commenced 15 years ago. For very many years the cause of cancer had been unsuccessfully sought, and he suggested that investigation of ætiology was not the only line of research that should be followed. It was necessary to explain to the public that, while the cause of cancer was being sought, attempts were also being made to secure better and more effective treatment. Dr. Burrows, of the Commonwealth Department of Public Health, told how for several years the Commonwealth Government had been endeavouring to foster cancer research and treatment in Australia. Subsidies amounting to £13,200 had been paid since 1924. The two most important problems were to find means of securing early diagnosis of cancer and of affording every member of the community an opportunity to obtain the latest and most up-to-date forms of treatment. The purchase of radium by the Commonwealth Government had tended to focus interest in treatment and research which had been steadily growing in Australia. The object of the Government was to provide a national system by which every member of the community could obtain cancer treatment of the highest class. Skilled surgical treatment was already available. What was necessary was the provision of other services. Dr. L. M. McKillop, of Brisbane, speaking on the prevention of cancer, said that medical men, as a profession, were not doing what they should towards prevention. Dr. J. L. Jona, of Melbourne, made an urgent plea for the creation of a central medical research council for the coördination of the work now proceeding all over the Commonwealth. He pointed out that under the present condition men who were making investigations in one State might not know what was being done elsewhere.

Radiation and Living Cells.

Prof. H. G. Chapman, Director of Cancer Research in Sydney, said that during the last five years a team of investigators had gathered in Sydney to learn more about the action of radiation on living matter. The study had mainly been confined to the action of X rays. The experiments of Dr. W. Moppett had shown that a beam of rays of so few adjacent wavelengths as to be termed homogeneous, might be as active as a mixed beam several thousand times as powerful physically. He had noted that some wavelengths caused atrophy of the cells of the chorio-allantoic membrane of the chick embryo, whilst others produced hypertrophy; other wave-lengths of the same intensity appeared to be without any biological activity. Further, the simultaneous application of beams of radiation with antagonistic action on tissues led to no biological effect on the membrane. It had been shown that several homogeneous beams of rays were potent biologically. The physicists in the

Sydney team had observed these wave-lengths to be the discontinuities in the adsorption of rays by lead, uranium, and molybdenum. Chemical analyses had shown lead and uranium to be present in the eggs used in these researches. It thus appeared that there was evidence that the heavy metals produced an exceptional adsorption of radiations of certain wave-lengths. Whether this adsorption was connected with the biological results remained to be seen. A study had been begun to ascertain whether the properties of lead as a catalytic agent were altered by the adsorption of X rays. Attention had been directed in Sydney to the way in which radium brought about the disappearance of new growths, and it seemed that immunological processes were concerned. Research had been undertaken to ascertain whether immunisation could be produced in the human subject by injection of proteins of tumours. Evidence was accumulating that antibodies might be produced against the proteins of the multiple melanotic sarcomata of man.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Royal Society of Edinburgh.

Sir Edward Sharpey-Schafer, the physiologist, has succeeded Sir Alfred Ewing, the physicist, as President of the Royal Society. In his retiring address Sir Alfred gave a masterly sketch of the progress of science in the 57 years of his experience, and emphasised the strong drift now manifest from physics to biology. He almost seemed to suggest that, for the time being, physics may be regarded as a series of extinct volcanoes, while biology shows an immense continent for exploration. But it is to be remembered that Einstein and Eddington are still young, while J. J. Thomson, Rutherford, and their many distinguished pupils are still with us. The quantum theory as well as general relativity have yet to be made intelligible and brought into coherence with one another, and with the ordinary experiences of life. The urgent problem for the physicist is to project an atom that will be identically the same for living matter as it is for dead matter, and on that problem some mathematical physicists are actively engaged. But unquestionably the interest in biology is growing every year. Sir Edward Sharpey-Schafer is not only a distinguished physiologist, but the symbol of a great biological movement.

Animal Breeding Department.

The work of this department, under Prof. F. A. E. Crew, is at last persuading practical breeders and farmers that research yields results of outstanding importance, and that science is a genuine guide to stock-rearing and stock selection. Recognition of this is seen in a gift to the department of £30,000 by Mr. T. B. Macaulay, president and managing director of the Sun Life Assurance Company of Canada. The wealthy corporation over which he presides has before now shown itself mindful of pioneer scientific effort. Mr. Macaulay, whose father was a Lewis man, recently presented a new wing, fully endowed, to the Lewis Hospital. The department has also received a similar gift of £30,000 from the Rockefeller International Board, and £10,000 from Lord Woolavington.

A Children's Ward for Nose and Throat Cases.

A special ward of 12 beds for the treatment of ear, throat and nose cases has been added to the Royal Edinburgh Hospital for Sick Children. This brings the total beds to 132. The new ward unit includes a properly fitted doctor's room, where minor operations and dressings can be done. About 1000 operations annually are performed in the hospital for adenoids and tonsils, and in 1927 50 mastoids were treated. The number of new patients attending this department rose from 767 in 1927 to 1200 in 1928, and the ward will make it possible to take in for short periods a much larger number than hitherto. Many adenoid and tonsil cases require indoor care after operation, and to send them home direct from the out-patient department is often very undesirable. In accepting the care of the ward Dr. Douglas Guthrie, who has been aural surgeon to the hospital since 1919, described the ward as a notable addition which would certainly prove a real boon to the patients.

The Medico-Chirurgical Society.

At a meeting of the Medico-Chirurgical Society of Edinburgh on Oct. 30th new officers were elected to fill the vacancies caused by the annual retirements. The office-bearers for the coming year are as follows:—

President: Prof. G. Lovell Gulland. Vice-Presidents: Dr. R. A. Fleming, Mr. J. W. Dowden, and Dr. E. F. Armour. Councillors: Dr. Charles McNeil, Dr. Andrew Ritchie, Dr. Murray Wood, Mr. J. W. Struthers, Dr. C. W. Somerville, Dr. W. Fordyce, Dr. H. G. Langwill, and Dr. Alex. Goodall. Treasurer: Dr. Macrae Taylor. *Secretaries*: Mr. A. Pirie Watson and Dr. H. L. Watson Wemyss. Editor of Transactions: Dr. Fergus Hewat.

PUBLIC MENTAL HOSPITALS.

SCIENTIFIC AND RESEARCH WORK.

THE first part of the Fifteenth Annual Report of the Board of Control, which we reviewed in a leading article [1] some weeks ago, deals with the administrative work of the public mental hospitals. The second part of the Board's report [2] contains, in addition to the entries of the Commissioners at the various hospitals and some statistical tables, the reports of the research carried out at the institutions throughout the country.

At *Birmingham*, as in previous years, work has centred round chronic infections, especially of the nasal sinuses and intestinal tract, and an attempt is being made to correlate the findings with disturbance of the pituitary gland, endocrine imbalance, and local damage to brain tissue. A chronic infective process has been found in a large proportion of cases, and in some it has been possible to trace it back to an acute infection such as measles, influenza, or scarlet fever. The areas of unresolved residual infection start a long chain of physical, and ultimately of mental symptoms. The relationship of actinotherapy to focal sepsis has been investigated; it appears that ultra-violet light causes an exacerbation reaction in "closed sepsis," and a healing reaction with diminution of symptoms in "open" or opened sepsis. An inquiry into the relation of mental symptoms to phases of the reproductive cycle has revealed a "menstrual reaction," or intensification of conduct disturbance during the premenstrual and menstrual phases, and a "moliminal reaction" or similar periodic intensification during the amenorrhœa of mentally disordered patients. The appearance of these reactions indicates that an ovary is still functioning, although it may be a diseased one. Bacteria have been found to pass from a diseased sphenoidal sinus to the pituitary gland, and it is believed that signs of pituitary disorder may be set up by a closed sepsis of this kind. An investigation into the Wassermann and Widal reactions of 176 mentally defective children at the Monyhull Colony has suggested an ætiological relationship between mental defect and gastro-intestinal infection in early life. Only 3 per cent. gave a positive Wassermann reaction.

At the *Cardiff City Mental Hospital* an inquiry is being made into the possible ætiological significance of a filtrable virus in dementia præcox. Work on blood-cholesterol has been published in THE LANCET (Feb. 23rd, 1929) and tends to show that the blood-cholesterol is a little lower in the pre-paroxysmal than in the paroxysmal phase of epilepsy, but shows only slight changes with the menstrual cycle. Work on the hydrogen-ion concentration of the blood and urine is being continued.

---

[1] THE LANCET, Oct. 5th, p. 719.

[2] H.M. Stationery Office. Pp. 360. 9s.

The *West Riding Mental Hospital* at *Wakefield* investigated a number of cases of dysentery; at *Wadsley*, Sheffield, malarial treatment was tried for three cases of dementia præcox, one of which showed steady improvement. Eight others were treated with hormone extracts, and two of them improved enough for discharge. There are a number of post-encephalitic cases in the hospital, and these are being investigated. Some benefit has been obtained in parkinsonism from a daily morning injection of hyoscin followed by two oral doses of stramonium in the afternoon and evening. At the *Storthes Hall Hospital*, *Kirkburton*, the Meinicke turbidity reaction was tried and found to be a valuable auxiliary to the Wassermann reaction, rapidly and easily carried out.

Of the *Lancashire Mental Hospitals*, that at *Lancaster* was occupied with an intensive antityphoid campaign, as sporadic outbreaks had occurred in the two previous years. Eight carriers were identified and no further cases have occurred. Malaria treatment is followed up by tryparsamide in general paralysis, and the relationship between the malaria infection and the cytological formulæ of the blood have been studied. The effects of ultra-violet light have been noted; the best results are obtained in debilitated patients who refuse food, and in stuporose melancholics. Schnee baths have been found useful for rheumatoid arthritis, sprains, and synovitis, as well as in the after-treatment of fractures, and as a general tonic in muscular affections. At *Prestwich* the malarial treatment has been studied. At *Rainhill* a number of cases of encephalitis have been examined bacteriologically and treated with autogenous vaccines. Cases of general paralysis have been followed up, and the conclusions arrived at are that malarial treatment alone is as effective as malaria followed by tryparsamide, but that tryparsamide acts as a general physical tonic and allays motor restlessness so that the pyrexial attack is less dangerous. It is, however, apt to cause serious complications, especially visual and hepatic disturbance, and must be given cautiously and controlled by the lævulose test and van den Bergh reaction. No case has been completely cured, if cure be taken to mean complete remission of mental symptoms, serological changes, and physical signs. Dr. C. M. Bamford calls attention to a special acute type of dementia præcox, characterised by restlessness, confusion and impulsiveness, lasting for a few months, with very intense physical deterioration, no tendency to remission, and early death. In all the cases examined post mortem he has found a large macrocephalic brain with a complex convolutional pattern, a marked fibrosis of all the solid viscera, especially the liver, kidneys, and ductless glands, and an infantile cardiovascular system. At *Whittingham* the Kafka paraffin reaction of the cerebro-spinal fluid has been found to agree in almost every case of general paralysis with the Lange gold and colloidal gamboge tests, but not to show meningitic curves. Tubercle bacilli have been demonstrated in the fæces in unexpected cases by the Ligroin and Zeihl-Neillson methods. It has been assumed that puerperal insanity is of two types: melancholia produced by pressure of the uterus on the splanchnic nerves, causing increased blood pressure, and mania due to a toxic factor producing cerebral irritation. Corresponding treatment has given good results; in mania a binder over several layers of towelling is applied, with the aim of increasing arterial pressure by increasing abdominal pressure. The Boltz test has been tried on 346 cases; it is only positive in general paralysis and does not always agree with the globulin test, nor is its absence a reliable indication of the absence of general paralysis. It tends to change after malarial treatment, but not as often or as rapidly as the globulin test.

The *London County Mental Hospital* at *Banstead* submits a report on the treatment of general paralysis with relapsing fever, saprovitan and milk injections. None of them was quite as good as malaria, and saprovitan was distinctly disappointing. It seems probable that the milk reaction is due to incomplete sterilisation and not to a genuine protein reaction. Malarial treatment is also being investigated at *Bexley*. At *Claybury* the Meinicke micro-reaction in the serum and the hydrogen-ion concentration in the urine have been investigated. Malaria has been tried in idiopathic epilepsy, but apparently only causes temporary benefit. At *Horton* ultra-violet light was found most useful in toxic cases and melancholias associated with the menopause. Malarial treatment here is made the subject of intensive research and not given as a routine only; a quartan strain is being tested. At *West Park* the oculogyric crises of encephalitis have been studied; suggestion seems the most potent factor in shortening or preventing attacks. Interference with normal cortical control accounts for the increased suggestibility of these patients, as well as for the release phenomena of different subcortical centres, causing tonic fits, ocular spasms, respiratory crises, myoclonias, emotional facility, and paradoxical reactions. A large proportion of the encephalitics who suffer from oculogyric crises subsequently require certification. The ætiology of alcoholism has been investigated at the *Maudsley Hospital* and attention drawn to the fact that we know almost nothing of the anatomical and biochemical basis of the euphoric and narcotic effects of alcohol, of addiction and distaste, and of susceptibility and immunity. Tryparsamide has been found valuable for general paralysis, but its action was enhanced by combination with malaria. The sedimentation velocity of erythrocytes in the psychoses has been studied but found of no diagnostic value except in recognising pulmonary tuberculosis in cases where the patient cannot give intelligent coöperation. The *Central Laboratory* of the London Mental Hospitals has continued its work on the pathology of schizophrenia and the histology of general paralysis. It has been found that the primary disturbance in the former lies in the inexcitability of the respiratory centre, a condition closely resembling that of normal sleep. The acid-base equilibrium was found in every way similar to that of a normal sleeping man. The absence of spirochætes in the brains of general paralytics after malarial treatment has been confirmed by numerous examinations. The stretch reflexes have been studied and work has been done on the relation of muscle tension to mental effort.

Research into the relation of mental disorders and the menstrual cycle is being continued at the *Cheshire County Mental Hospital* at *Chester*. Amenorrhœa has been found in one case in seven and dysmenorrhœa in one case in five of established psychosis, while a high percentage of epileptics show pre-menstrual or menstrual grouping of the fits. At *Macclesfield* light therapy has been investigated and also the liability to suicide in various psychoses. Suicide seems to depend on a faulty physical inheritance, in which endocrine malformation is a prominent factor.

At the *East Sussex County Mental Hospital* the Kahn test has been found less reliable than the Wassermann and the urochromogen test for tuberculosis was found very unreliable. Minchin's technique for identifying tuberculous yeasts is being tried and the acidophilus and streptococcal contents of the intestine have been investigated; acidophilus protection seems to be markedly deficient in mental patients.

At the *Dorset County Mental Hospital* a search for typhoid carriers and a leucocyte study has been carried out. The Meinicke micro-reaction, the Takata-Ara colloidal reaction, Buscaino's black reaction, and Scheiner's reaction are being investigated.

At the *Croydon Borough Mental Hospital* Kahn's test has been found simpler and more reliable

Wassermann reaction. In a few cases of epilepsy ephedrine has been found more efficacious than luminal or bromides, and glucose has been found an invaluable adjunct to the treatment of asthenic cases. The sedimentation-rate of the erythrocytes has been studied; it is markedly increased in pulmonary tuberculosis, carcinoma, salpingitis, and diabetes mellitus. Ultra-violet light, although useful for skin disease, has not caused any improvement in mental cases.

The Vernes tests are being investigated at the *Leicester City Mental Hospital.* A number of cases of dysentery were studied during the year and general paralytics were treated with malaria.

St. Andrew's Hospital, Northampton, puts all its patients through a routine scheme of research and various forms of hydrotherapy have been studied. A detailed examination is being made of the bacteriology of the stomach and intestine. At *Wonford House, Exeter.* the hæmatopoietic tissues have been found to be functionally impaired in general paralysis; they are unaffected in non-paretic syphilis. Consequently an infection calling for polymorphonuclear leucocytosis will flood the blood of a paretic with immature leucocytes. The depression of leucopoietic activity is thought to account for the ease with which bedsores are developed and the liability to intercurrent infection. It is suggested that it is futile to over-stimulate an exhausted system, and that pyrexial treatment should only be used when stimulation of the leucogenic functions is likely to be successful—i.e., at the earliest stage or as a preventive routine measure in the secondary or tertiary stages of syphilis. Pyrexial treatment given to a patient with a poor leucocytic response only hastened the paresis.

This brief summary by no means covers all the scientific work undertaken at the mental hospitals. It takes no account of the articles sent to medical journals and papers read at meetings of the Royal Medico-Psychological Association. When it is realised that most of this work is done in remote country places, often far removed from the encouragement of contact with other workers and without the stimulus of team enthusiasm, the record is highly encouraging. It is true that there are more than a hundred mental hospitals and many of them are silent on research, but the printed reports are enough to show that the scientific spirit is alive in the mental hospital service, and we are happy to call attention to it.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. N. A. H. Barlow to be Surg. Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj. H. F. Joynt retires on retd. pay.

ARMY DENTAL CORPS.

Lt. E. C. Browne, temp. Dental Surg., Gen. List, to be Lt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. A. R. C. Parsons having attained the age-limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL FORCE.

Capt. E. R. Lovell to be Maj.

ROYAL AIR FORCE.

J. G. Skeet is granted a temporary commission as a Flight Lt.

Flying Officer J. J. MacAndrews resigns his short service commission.

Flying Officer H. D. Humphreys is promoted to the rank of Flight Lt. (Dental) on promotion to the rank of Captain in the Army Dental Corps.

INDIAN MEDICAL SERVICE.

Lt.-Col. (Bt. Col.) W. H. Leonard to be Col.

Temp. Lt. Sat Chit Anand relinquishes his temp. commn.

"Audi alteram partem."

JAMES BLACK'S DESCRIPTION OF CONTRACTILITY OF CAPILLARIES (1825).

To the Editor of THE LANCET.

SIR,—In the second edition of Krogh's monograph on the capillaries, which you reviewed last week, attention is drawn to a group of investigations on the contractility of the capillaries carried out early in the nineteenth century. Mention is made of Wilson Philip's studies, and also of those of Johannes Müller, who sought evidence for or against the existence of peripheral propulsive agents which might assist the heart in overcoming the peripheral resistance. Krogh, however, and also Lewis, fail to mention the interesting study of James Black (1788?–1867), who, in 1825, published in London a book of 176 pages, entitled "A Short Inquiry into the Capillary Circulation of the Blood; with a Comparative View of the More Intimate Nature of Inflammation." Black described *in no uncertain terms the phenomenon now* referred to as the "red reaction," and he observed beyond any possibility of doubt the independent contractility of the capillaries. The following protocols of two of his experiments, which occur on pp. 54 and 55 of his book, will serve to indicate the nature of his observations.

"*Exp. 4. On a frog.*—The natural circulation of the arteries in the web almost invisible, and without any red colour; but as soon as it was discovered, it was observed to circulate with considerable velocity, and the globules were not easily to be traced. Extension and gentle fastening of the foot even by the fingers increased the flow of blood, and soon filled many of the colourless vessels with red globules. The application of Aq. Ammon., and more particularly of the salt solution, soon rendered the whole capillaries visible and of double their former diameters; the circulation becoming slower, and congestion following in the veins, and lastly in the arteries. The brain was crushed, and the circulation observed in the foot previously unexperimented upon. The vessels sooner than before became more visible, the circulation also became retarded, and congestion took place in the order of vessels as before remarked; but the circulation continued 20 minutes after the injury of the brain, and, lastly, the blood slowly retired from the smaller vessels of all descriptions, and left the web pale and flaccid."

"*Exp. 5. The web of a young duck's foot was made the subject of this experiment.*—The veins, in beautiful branches, were easily seen by a common magnifying glass, but the arteries were only visible after some stimulation. The web could not be rendered transparent enough to see the red globules by the microscope. Aq. Ammon. was applied to both sides of one of the divisions of the foot; in two to four minutes great contraction took place in the large vessels; so much so, that many branches were rendered invisible, and others appeared like the finest hairs, which, before in their natural state, seemed three times the diameter. It was not a mere recession of the blood, for the line of the larger vessels was very distinctly contracted and well defined. After the space of about four minutes, all the vessels acquired their former natural diameters, and still further enlarged to complete phlogosis of the part, or to what may be termed inflammation. A fresh application of Aq. Ammon. produced a fresh contraction, but it was not near so complete as the former. The other foot was treated with a saturated solution of Mur. Sodæ, which application was soon followed by great enlargement of the vessels, especially of the larger veins in the web, which seemed much congested, until bathed on both sides with Aq. Ammon. when after five minutes general contraction was produced, and many of the small vessels were rendered invisible. During the above experiment the animal scarcely struggled."

On the basis of these and other observations Black draws 12 carefully worded conclusions, several of which may be given in his own words.

"*Third.*—The healthy and natural circulation in the capillaries depends, directly, on a tonic or *tensive* state of their delicate tubes; and immediately, on some power inherent in the part, a degree of which power seems to reside in the blood equally with the vessels, and its energy depends more on the integrity or vitality of the part or parts of this system than upon any impulse derived from the heart."

"*Fifth.*—A strong stimulus suddenly applied, in a short time, produces a contraction of all the fibres of the part and a *diminution of the diameters of the whole classes of* vessels, but more particularly of the arteries, which is followed, at a greater or less distance of time, by a corresponding dilatation—according to the extent of which, the phenomena of inflammation will be more or less observable; and more so, if the *vis a tergo* be powerful or stimulated."

"*Sixth.*—A gentle or lesser stimulus produces an evanescent contraction, followed by relaxation, increased redness, and a slight acceleration of blood in the *leading* capillary arteries and veins; owing, it seems, to the increased capacity of the distended reticular vessels, while the former are yet relatively contracted."

"*Seventh.*—The circulation in the capillary system is independent of the controul [sic] of the heart, except so far as this organ affords a constant pressure and a ready supply of blood, upon which the capillary vessels may act; and it is still more independent of the brain."

"*Tenth.*—The condition of a part, in what is termed inflammation, is essentially seated in the capillary vessels, and primarily and chiefly in those of the veins."

Black then points out that his observations are in sharp contradiction to the conclusions of Haller (1760) that the capillaries were passive agents, whose diameter depended only upon the pressure of blood passing in them. The author considered the possibility that the capillaries may act as peripheral hearts, but draws no definite conclusion. In discussing the structure of the capillaries, he says, "the muscular or elastic tunic of the larger arteries, about which there has been so much controversy, is either lost in the capillary tissue or is so *entirely attenuated* that it is incapable of demonstration, even by the aid of a strong microscope."

Black records (p. 50), that his observations "were instituted in the summer of 1823. They would have been prosecuted to a much greater extent if an amaurotic affection of one eye of the experimenter had not made its appearance during these and some other optical pursuits." He was born in Scotland, and was admitted a Licentiate of the Edinburgh Royal College of Surgeons in 1808 and M.D. of Glasgow in 1820. From 1810 to 1839 he practised at Bolton, and then moved for ten years to Manchester. In addition to his medical writings, which were numerous, he *contributed several papers on* geology and Roman archæology to the Manchester Philosophical Society.

I am, Sir, yours faithfully,
J. F. FULTON.

Magdalen College, Oxford, Oct. 15th, 1929.

PS.—Since writing this letter I have come upon a work of Marshall Hall entitled "A Critical and Experimental Essay on the Circulation of the Blood, especially as observed in the Minute and Capillary Vessels of the Batrachia and of Fishes" (London: 1831, 187 pp., 10 plates). The anatomical distinction between arterioles and capillaries is here clearly set forth, but the writer was unable to detect independent contraction of capillary vessels, and he concludes that "every fact relative to the capillary circulation leads us to ascribe its various phenomena to forces impressed upon it from without," and "there is nothing of satisfactory evidence or argument for an automatic power in them" (p. 90). Marshall Hall exerted a powerful influence upon contemporary physiological thought and his conclusions were undoubtedly responsible for the scant attention which the observations of Black and Wilson Philip received.—J. F. F.

TANNIC ACID FOR BURNS.

To the Editor of THE LANCET.

SIR,—The results of a questionaire sent out to various hospitals and authorities have been considered by the medical advisory committee of the Industrial Welfare Society. The consensus of opinion shows that, although it has been proved to be of considerable value, especially in hospitals, it should be used only under medical supervision and not as a first-aid application for burns by the general public or ambulance attendants. Nor in the nursery, owing to the complicated character of the treatment, and the extremely poisonous nature of the corrosive sublimate suggested to be used with the tannic acid.

I am, Sir, yours faithfully,
D. A. COLES,
Chairman, Medical Advisory Committee of the Industrial Welfare Society.

51, Palace-street, Westminster, S.W. 1, Nov. 1st, 1929.

THE DIAGNOSIS OF LARYNGEAL CANCER.

To the Editor of THE LANCET.

SIR,—Sir James Dundas-Grant has mentioned my name. May I reply? The battle of the biopsies will be fought by laryngologists as long as that of white and brown bread by dietitians, but the recent discussion and a subsequent correspondence with Sir James has suggested to me a classification that may prevent our talking at cross-purposes.

Class A.—The removal of a piece of the primary lesion by an endolaryngeal method: (1) when any subsequent operative treatment will be a laryngectomy or pharyngectomy; (2) when any subsequent operative treatment will be a laryngo-fissure or the making of a window in the thyroid cartilage for the insertion of radium.

Class B.—The removal of a lymph gland for evidence of secondary involvement.

In *Class A* (1) I will agree that a biopsy may be made before submitting the patient to an operation of such a magnitude. In such cases the growth is extrinsic or if primarily intrinsic is becoming secondarily extrinsic. Further, it is large. For these two reasons it is probable that the piece removed will be large enough and central enough to produce a section from which a certain diagnosis may be made.

It is in *Class A* (2) that the difference of opinion prevails. I belong to the school that would make the diagnosis by clinical observation, by waiting and watching, and the exclusion of other diseases by general medical and by bacteriological and serological investigations. In my opinion it is wrong to attempt a biopsy in these cases. The growth is intrinsic and limited to the cord, and it is small. Therefore there is a chance that the piece removed will be small and from the periphery with the result that the section may not enable a definite decision to be made. The diagnostician is then in a worse position than before; he must fall back upon the policy of waiting and watching, but under great difficulties. The wound must first heal, and when it has healed the observer cannot be sure what part of the change from the original picture is due to the trauma, and what part is due to an extension of the disease.

Further, in both cancer and tuberculosis the removal of a piece may do harm. In cancer it may result in a rapid extension of the growth so that it passes from the stage where the relatively minor operation of laryngo-fissure must be replaced by the major one of laryngectomy. In tuberculosis it is equally harmful. To call the operation of laryngo-fissure "life-endangering" in tuberculosis may be correct; but one cannot deny the science epithet to the removal of a piece for microscopical section.

A study of the cases recorded at the last meeting of our section bears out this view. Sir James showed microscopical sections of two cases. In each they confirmed that which he had made. In his second case the patient was referred to him as one of tuberculosis, and I infer that he took a piece for microscopical section because he disagreed with this. In the third case the patient was sent to him with the diagnosis of growth and he thought it tubercle. Again, the section proved him to be right. In neither case therefore did the sections help him in his diagnosis; they merely gave him pathological support in his difference of opinion with others. He produced no section in which his clinical diagnosis was proven wrong and by which he was saved from calamity. Against biopsy we have Dr. Andrew Wyllie's case (*Proceedings*, 1929, p. 72) where the microscopist was wrong, and Dr. Jobson Horne's case (*Proc.*, p. 68) even after operation the opinions of varied. To these we may add the classical case of the Emperor Frederick and similar cases where the microscopical evidence from the part removed has been inconclusive and has led to delay and a terrible suspense. The only evidence produced in favour of biopsy at this meeting was negative. Dr. Jobson Horne instanced (*Proceedings*, pp. 66, 67) four cases where the larynx was opened for a tuberculous lesion which had been thought to be cancer. Apparently these were gleaned from the history of laryngology over a period of 50 years.

Class B does not afford many opportunities for performing a biopsy and none from the cases that come within Class A (2). In cases coming under Class A (1) section of a gland may clinch the diagnosis as in the following patient. A man came up to the clinic with a cauliflower mass in the larynx which looked like a carcinoma. He had such dyspnœa that it was necessary to do a tracheotomy on the next day before the complete medical examination could be made. While doing this operation the crico-thyroid gland was found to be enlarged: the section proved to be tuberculous. This was subsequently confirmed by examination of the lungs.

I am, Sir, yours faithfully,

Welbeck-street, W., Nov. 4th, 1929. T. B. LAYTON.

THE MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LIMITED.

To the Editor of THE LANCET.

SIR,—In reply to Mr. Bowdler Henry's attack on the board of this Society, I should like to say—

(1) that I was present at the general meeting and heard the discussion on Dr. Harvey Hilliard's resolutions and was perfectly satisfied with the board's treatment of them which was at once sympathetic and firm; and

(2) that as the unanimous recommendations of the directors, as set out in the annual report, were directly attacked it was only to be expected that the board would send out for proxies.

I am, Sir, yours faithfully,

Chelsea, S.W., Nov. 1st, 1929. E. F. THOMAS.

THE BROWN v. WHITE BREAD CONTROVERSY.

To the Editor of THE LANCET.

SIR,—The letter by Dr. S. H. Belfrage in THE LANCET of Nov. 2nd, asking those who hold opposing views to those of Prof. V. H. Mottram and Miss Gladys A. Hartwell to express their views on these experiments, induces us to make the following comment. Mottram and Hartwell have now definitely abandoned their former contention that white bread contains a considerable amount of vitamin B, and is not markedly inferior in that respect to wholemeal bread or germ bread. They now admit that the two last-named types of bread are richer in vitamin B, although they still conceal the fact that white bread is exceedingly poor in vitamin B. Incidentally they make an error in suggesting that the controversy has been complicated by the advent of germ breads. If they had consulted some such standard text-books on nutrition as Hutchison's "Food and Principles of Dietetics," they would have found that germ breads had been manufactured and consumed long before the vitamins were discovered. It is therefore now agreed that white bread is inferior to wholemeal bread and germ bread in so far as its vitamin-B content is concerned. Whether this is a matter of importance to the general public or not may be left to the judgment of your readers.

Mottram and Hartwell now shift the discussion to a new ground. They say that "an ordinary diet" contains so much vitamin B amongst other things that "the deficiencies of white bread" are amply compensated. In saying this they beg the whole question at issue. We may quote here the following sentences from our previous paper[1]:—

> "On a varied diet which includes milk, butter, eggs, porridge, potatoes, and other vegetables, the absence of vitamin B from bread may not be a serious defect. But the people who can afford such a diet do not eat much bread anyhow. It is among the poorer classes, and especially the children of the poorer classes, where bread represents the bulk of the daily diet, and where butter is replaced by margarine, that the absence of vitamin B from white bread has to be considered as a serious dietetic defect. Reports of medical officers of health show that many of these children live on a diet composed of white bread, margarine, jam, and fish, with perhaps some potatoes. Such a diet is certainly deficient in both vitamin A and B, and could be made adequate as regards the latter vitamin by the consumption of bread rich in vitamin B."

It will be seen that there is here again agreement between our views and those of Mottram and Hartwell, but it will also be seen that these authors evade the issue that according to the reports of medical officers of health many children live on a diet composed chiefly of fish, potatoes, white bread, margarine, and jam. This is not "an ordinary mixed diet," and from what we know of the vitamin-B content of the articles of food composing this diet, it is poor in vitamin B_1. It would not require long and costly experiments to prove whether on such a diet the partial substitution of wholemeal bread or germ bread for white bread as suggested by us would or would not have a beneficial effect.

The diet chosen by Mottram and Hartwell in their experiments, and called the "diet of the Essex agricultural labourer," is a very different one. Their experiments, incomplete as they admittedly are, prove that the diet is defective, and since the defects are not remedied by the substitution of bread rich in vitamin B for bread poor in it, all that one can conclude is that the defects of this diet cannot be remedied by the addition of vitamin B_1 alone. But when in the last sentence of their paper the authors make the bold assumption of implying that the diet called "the diet of the Essex agricultural labourer" represents the diet of the working classes of this country we cannot agree with them. There is no justification for this assumption. Nobody can lay down a definite diet as representing that of the working or any other class. Diet varies from household to household. The letter from Sir Bruce Bruce-Porter and the experience of medical officers of health referred to in the quotation from our paper paint a very different picture from that given by Mottram and Hartwell.—We are, Sir, yours faithfully,

J. C. MOTTRAM.
W. CRAMER.

Radium Institute, Imperial Cancer Research Fund,
Nov. 4th, 1929.

CURES AND PREVENTION.

To the Editor of THE LANCET.

SIR,—Dr. Ainley Walker makes a fine point. The fact cannot be denied that the injection of the antitoxin causes destruction of the diphtheria bacilli in the patient, whatever the exact method of that destruction is, and is therefore an intravital germicide. I will take him on the theoretical point he has made. Assuming, an assumption with which, perhaps, he will not agree, that the toxin is the ferment by which the microbe hydrolyses, therefore kills, the living tissues, in order to live, surely if the combining power of that ferment were neutralised, and the ferment, therefore, not capable of bringing about the digestion of the material, the microbe must die of inanition; the antitoxin can therefore quite properly be considered a germicide. If antiferments to X.Y.'s digestive ferments were injected into X.Y., causing his death by inanition, it would be a very efficient homicide.—I am, Sir, yours faithfully,

Harley-street, W., Nov. 1st, 1929. W. M. CROFTON.

---

[1] THE LANCET, 1927, ii., 1090.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Highlands and Islands (Medical Service) Fund.

The Scottish Office have issued the following explanatory memorandum in connexion with the legislation which the Government are introducing this session to authorise the removal of the existing limitation of the Government grant to the Highlands and Islands (Medical Service) Fund: "Subsection (1) of Section 1 of the Highlands and Islands (Medical Service) Grant Act, 1913, authorises the payment to the Highlands and Islands (Medical Service) Fund established under that Act of an annual grant of £12,000 out of moneys provided by Parliament to be applied for improving the medical service in the Highlands and Islands of Scotland. The Fund is administered by the Department of Health for Scotland in accordance with schemes made by the Department with the consent of the Treasury. Any unexpended balance of grant is not liable to surrender at the close of the financial year. Since 1920 the expenditure out of the Fund has been greater than the annual income, the excess having been met from unexpended balances of grant which accumulated during the war years, when it was impossible to give full effect to the approved schemes in the conditions then obtaining. These accumulated balances will be exhausted this year, and it is necessary to make further provision for financing the Fund. It is proposed to introduce legislation to remove the limitation of the grant to £12,000 by authorising such additional sum as may be annually voted by Parliament for the purpose. The additional sum proposed in any year will be included in the Estimates of the Department of Health for Scotland. It is estimated that the additional sum required to be so included will be £10,650 for the current financial year and from £20,000 to £30,000 in future years."

The Widows' Pensions Bill.

In the House of Commons on Wednesday, Oct. 30th, Mr. A. Greenwood, Minister of Health, moved the second reading of the Widows', Orphans' and Old Age Contributory Pensions Bill, and said that it was in accordance with their election pledges and the statement contained in the King's Speech that the Government had brought forward the Bill, and had undertaken a comprehensive inquiry into the complex system of social insurance that now existed. The Bill was a small instalment of a larger policy. The health insurance scheme, on the one hand, and contributory pensions on the other, were closely interlocked as regarded range of insurance and collection of insurance; but on the fundamental matters of finance and general organisation there were quite distinct principles at work. In consequence of the system having grown up piecemeal—and he was not complaining about that—different principles entered into the conception of services that were provided for closely related needs, and there had been distinct forms of administrative machinery set up for services which were broadly similar in purpose. Because of that, and the other problems which were now in the forefront of public opinion, it was the view of the Government that the time had arrived when they should take stock of the existing system of social insurance, and a Committee of the Cabinet was engaged on a survey of the various schemes, an analysis of the various and complex problems which schemes developed on independent lines inevitably brought into existence, and consideration of the very large and important questions of the relations between insurance, on the one hand, and the various forms of social problems which were met outside of insurance on the other. The Bill before the House only professed to deal with the more important problems affecting the insured people arising out of the Act of 1925; the other and larger issues were precisely those questions which were now being examined by the Cabinet. It was the desire of the Government to build up by stages towards a comprehensive, adequate, harmonious system of social insurance which would enable all citizens effectively to meet the misfortunes and risks of life. To that task they had laid their hands; they would not consider that they had completed it until they had fulfilled their obligations. But there were certain amendments of the Contributory Pensions Act that could and should be made at once. The object of this Bill was to make those amendments. The main principle of the measure was to bring within the scope of the pensions scheme persons of the same class as those for whom the original Act was intended, and who by pure accident were at present excluded from its provisions. Under this proposal would be brought within the scheme as a whole all those women whose husbands could not participate because they were over 70 when the Act came into operation, or because they died before the appointed date of the Act of 1925. At the same time opportunity had been taken to relax certain restrictions which experience of the working of the Act had shown to be necessary, and to enlarge some of the provisions which experience had shown to be desirable. By July 1st, 1930, something like 210,000 pre-Act widows would be brought within the scope of the Bill for pensions. These would be the elderly widows who were over 60. On Jan. 1st, 1931, there would be brought within the scope of the Bill the class of widows between 55 and 60 amounting to 85,000. That meant that about 290,000 widows would begin to benefit as soon as they reached the age of 65. Provision was being made for round about 500,000 pre-Act widows in the present Bill. He emphasised that number, because to-day there were about 200,000 post-Act widows receiving pensions. The Bill also proposed to do something for the pre-Act widows with dependent children. By prolonging the right to pension until the youngest child reached the age of 16, about 18,000 widows would receive this benefit. Finally, old age pensions would be given at 65 to 24,000 wives of men who happened to be over 70 before pensions began to be paid.

For the period up to 1936 the additional expenditure would cost on an average about £8,000,000 a year. The Chancellor of the Exchequer proposed to increase the Treasury contribution from £4,000,000 to £9,000,000 a year; but in 1936—with the flat £4,000,000 contribution—a very substantial increase in the State contribution would be required. In order to reach the day of larger contributions by easy stages the Chancellor of the Exchequer proposed each year to increase the State contribution by £1,000,000 until it reached, under the proposals before the House and the present Act, a maximum of £21,000,000 a year.

The Bill was read a second time.

New Bills Introduced.

On Friday, Nov. 1st, Mr. G. Hirst presented a Bill to amend Subsection (4) of Section 9 of the Workmen's Compensation Act, 1925.—Mr. Alpass presented a Bill to consolidate and amend enactments relating to midwifery, &c. Both Bills were read a first time.

Unemployment Schemes and Public Health.

On Monday, Nov. 4th, Mr. J. H. Thomas, Lord Privy Seal, made a statement in which he described the progress of his plans for dealing with unemployment. Referring to the severe drought experienced during the past summer, the right hon. gentleman said that every water authority in the country ought to be alive to the dangers of such a situation, and there would be no excuse if there was a repetition next year of the dangers and hardships which the nation had passed through. He had circularised all the authorities and those responsible for water supplies, both large and small, and he was able to announce that included in the £11,000,000 which was to be spent on schemes already approved was a considerable number of large water schemes. No water authority would be held blameless next year if they had failed to take advantage of the opportunities now afforded to them.

During the debate which followed Mr. Thomas's statement—

Sir R. Aske suggested that something might be done to deal with the unemployment in the building and allied trades, which represented 12 per cent. of the whole problem. There was a large amount of frightful overcrowding in all the great industrial centres. This had a very bad effect on the health of the people. The Government should take their courage in both hands and deal with this overcrowding.

Mr. Thomas said that one of the first measures of the Government this session would be a Slum Clearance Bill to deal with one side of the housing problem. He had urged the municipalities to take advantage of the Government's facilities to help them to undertake work which ought to have been done long ago. That offer was still open.

Sir R. Aske, while expressing satisfaction at Mr. Thomas's statement, said that slum clearance would not meet the difficulty. There was an actual shortage of houses, and they must build more houses before they destroyed the slums. The health of the people was suffering, and if the Government did not build the houses now they would have to build hospitals in future. The Government should find out how many houses were necessary, and provide one house for one family, if possible. If they did that, they would greatly benefit public health and would save a vast sum which otherwise would have to be spent in future on public health services.

Protection of Dogs Bill.

On Nov. 4th Sir R. Gower presented a Bill to prohibit the vivisection of dogs. The Bill was read a first time.

HOUSE OF COMMONS.

THURSDAY, OCT. 31ST.

Washington Eight Hours Convention.

Sir **NICHOLAS GRATTAN-DOYLE** asked the Minister of Labour when it was proposed to introduce the measure to give effect to the Washington Hours Convention.—Miss **BONDFIELD** replied: I hope to introduce the Bill at an early date.

Various Industries (Silicosis) Order.

Mr. **HOLLINS** asked the Home Secretary when he proposed to make an order to extend the present Various Industries (Silicosis) Order, so as to make provision for the payment of compensation in the case of partial incapacity due to silicosis.—Mr. **CLYNES** replied: I am anxious to provide for the partial disablement cases as soon as practicable, but adequate medical arrangements must first be made. As my hon. friend is aware, this difficult question has been under investigation by a Departmental Committee. The Committee has now reported, and a copy of the Report has been laid before Parliament. I concur generally in the arrangements recommended, but I am advised that they cannot be given effect to without further legislation. I am accordingly considering an amending Bill, which I hope may be introduced and passed into law during the present session.

Mr. **HOLLINS** asked the Home Secretary if he was aware of the abnormal number of cases of silicosis in the pottery industry for which compensation had been paid since Feb. 1st last, when the Various Industries (Silicosis) Order came into operation; and whether, in view of the serious nature of the incidence of silicosis amongst pottery workers, he would appoint a committee of inquiry to consider and report as to amendments to the present lead and dust regulations required to give adequate protection to the health of the workers engaged in the pottery industry.—Mr. **CLYNES** replied: A certain number of cases have come to the notice of the Department but I have no complete figures. As my hon. friend knows, the question of further preventive measures was very carefully investigated in 1927 to 1928 by a Departmental Committee (of which he was a member), which recommended various additional precautions, including periodic medical examinations in some of the most dangerous processes. It is intended to give effect generally to the proposals of the Committee, but I am not sure how far it may be practicable or desirable to attempt to deal with the subject pending the establishment of the new medical arrangements to which I referred in my reply to the last question. So far as I am aware, there is no need for the appointment of any further Committee.

Tannic Acid Treatment for Burns.

Dr. **VERNON DAVIES** asked the Home Secretary if he proposed to issue any instructions to factories and workhops in reference to the tannic acid treatment for burns.—Mr. **CLYNES** replied: The value of this method in the treatment of cases in hospital is demonstrated by the recent Report of the Medical Research Council, but its application o the first-aid treatment of minor cases of burns, which orm a great majority of the cases at factories and workshops, would not appear to have been explored. The Senior Medical Inspector of Factories has been asked to go into this, and the matter will be further considered on his report. Meanwhile I am hardly in a position to issue any instructions.

Experiments on Living Animals.

Mr. **FREEMAN** asked the Home Secretary whether his attention had been called to the further increase in the number of experiments on living animals, especially without anæsthetics, being 300,915 during 1928 and 44,078 more than in 1927; and whether he would consider the desirability of setting up a full inquiry into the matter with a view to preventing this practice, paid for in many cases by public funds.—Mr. **CLYNES** replied: The answer to the first part of the question is in the affirmative. The increase of experiments under Certificate A (i.e., without anæsthetics) is largely, if not entirely, due to an increased use of animals for the purposes of standardising drugs for use in medical practice, of diagnosing the diseases of patients under treatment, and of testing the purity of milk and other foods in the interests of public health. The whole question of experiments on animals was very carefully and thoroughly investigated by the Royal Commission on Vivisection which reported in 1912; and I do not consider that a further inquiry is called for.

Nursery Schools.

Mr. **KELLY** asked the President of the Board of Education the number of nursery schools in operation; and whether proposals were made for the opening of nursery schools in other areas.—Sir **CHARLES TREVELYAN** replied: The number of nursery schools in operation under the Board's regulations in England and Wales is at present 29. There are, in addition, 15 proposals before the Board for the establishment of nursery schools, and the provision of such schools is under consideration in a number of other areas.

Pollution of the River Lee.

Captain **AUSTIN HUDSON** asked the Minister of Health whether he had yet concluded his inquiries into the pollution of the River Lee; and, if so, what action he proposed to take.—Mr. **GREENWOOD** replied: I have had an investigation made. The nature of the stream makes the pollution problem difficult in this case. There has been an improvement, but the conditions are still not satisfactory. I propose to confer with the authorities concerned.

Birth Control Information.

Mr. **THURTLE** asked the Minister of Health is he had received a resolution passed by a recent conference of the National Council of Women's Societies, asking that local authorities should be permitted to give information on birth control to married women who desire it; if he was aware that this resolution was passed by a large majority; and if he was proposing to take any action to carry out the wishes of this representative body of organised women.—Mr. A. **GREENWOOD** replied: I have received this resolution, though I have not been informed by what majority it was passed. The question has been considered by the Government, and they do not propose to depart from the policy hitherto followed in this matter.

Ministry of Health Staff.

Brigadier-General **CLIFTON BROWN** asked the Minister of Health what was the number of the personnel employed by the Ministry of Health on June 1st, 1929; what are the numbers at present employed; and what was the increase or decrease in the cost.—Mr. **GREENWOOD** replied: The number of personnel employed by my Department on June 1st was 5883; the present number employed is 6006. The approximate annual increase in cost is £35,500.

Medical Officers on Local Authorities.

Dr. **VERNON DAVIES** asked the Minister of Health if his attention had been drawn to the fact that under the Local Government Act, 1929, many district medical officers and public vaccinators who had been members of county councils and county borough councils were ineligible for future membership unless they forfeited their appointments; and, as the experience of such members in health matters was of much value, would he consider some means by which the services of these practitioners could, when desired, be utilised on such county and county borough councils.—Mr. **GREENWOOD** replied: This matter has been before the Royal Commission on Local Government. Their report will be issued shortly, and any recommendation made will be duly considered.

Medical Research in India.

Major **GRAHAM POLE** asked the Secretary of State for India whether any steps had been taken in regard to the scheme, sanctioned by the finance committee of the legislative assembly in January, to remove the central medical research institute to Dehra Dun; and whether, especially in view of the objection raised by the All-India Medical Association to the removal of the institute to Dehra Dun, where there would be an absence of clinical facilities and of the scientific coöperation available in larger urban centres, the Government will examine the possibility of reconsidering the scheme.—Mr. **WEDGWOOD BENN** replied: The latest information I have is that work had not been started at Dehra Dun on Sept. 2nd. I will bring my hon. friend's suggestion to the notice of the Government of India, but I understand that they have already received representations on the same lines from one or more medical associations in India.

Manufacture of Dangerous Drugs.

Mr. **MANDER** asked the Home Secretary what was the number of factories in this country engaged in the manufacture of opium, heroin, cocaine, and other noxious drugs; the amount of capital involved; and the number of employees.—Mr. **CLYNES** replied: Eight firms are at present licensed to manufacture medicinal opium, heroin, cocaine or morphine (i.e., pure drugs under the Acts): five to manufacture medicinal opium; one to manufacture medicinal opium, morphine, and heroin: one to manufacture morphine, heroin, and cocaine; one to manufacture cocaine. I have no information as to the amount of capital involved or the number of persons employed, but the number is certainly under 50. I am sending the hon. Member a copy of the Annual Report of the British Government to the League of Nations.

Hospital Treatment for Orthopædic Patients.

Brigadier-General WRIGHT asked the Minister of Health whether representations had been made by county councils to have the legal right, which they did not now possess, to assist all needy orthopædic patients without regard to technical group distinctions; and, if so, whether he was prepared to introduce legislation to confer this right on them.—Mr. GREENWOOD replied: Representations on this subject have been received from one county council. I am advised that under Section 14 of the Local Government Act, 1929, county councils will, as from April 1st next, be empowered to provide all necessary hospital treatment for orthopædic patients.

Typhoid in London Area.

Mr. DAY asked the Minister of Health the number of cases reported of typhoid, and the number of deaths that had occurred in the London area for the three months ended to the last convenient date; and whether his officers had been able to trace the origin of these outbreaks.—Mr GREENWOOD replied: As regards the first part of the question the particulars required are as follows:—

Enteric Fever (Typhoid and Paratyphoid).—Deaths of London residents occurring in London or in metropolitan institutions.

Week ending	Notifications.	Outside London.	Week ending	Notifications.	Outside London.
July 6	2	1	Sept. 7	9	2
" 13	5	—	" 14	17	3
" 20	7	1	" 21	6	1
" 27	4	—	" 28	6	—
Aug. 3	6	2	Oct. 5	5	—
" 10	5	1	" 12	23	1
" 17	6	—	" 19	30	3
" 24	11	—	" 26	41	3
" 31	4	—		—	—
	Total ..	..	.. ..	187	18

(In addition there were two deaths occurring in London of non-residents of the County of London. The notifications in these cases are not included above.)

As regards the recent outbreak in South-East London, which is responsible for the large increase in notifications this month, my officers have coöperated with the medical officers of health of the districts affected. I understand that the source of this outbreak has not yet been definitely traced, but there is reason to believe that the infection is no longer operative.

FRIDAY, NOV. 1ST.

Medical Examinations of Pensioners.

Mr. RAMSBOTHAM asked the Minister of Pensions (1) the frequency with which ex-Service pensioners had to be re-examined before medical boards; and whether, to avoid the constant anxiety to the men and the cost of the inspection, he could accelerate the rate at which pensions were being stabilised; and (2) what classes of great war pensioners had their pensions stabilised and which had not; and to which class belonged the men suffering with eye trouble.—Mr. F. O. ROBERTS replied: Pensioners are medically examined at such intervals only as is essential to determine the rate of compensation due to them. I have full sympathy with the hon. Member's desire that final awards should be made as soon as possible in all suitable cases. This is, in fact, the practice of the Department, and already more than four-fifths of the men on the pension list, suffering from disabilities of all kinds, are in receipt of final awards. This proportion applies also to cases of affections of the eye.

MONDAY, NOV. 4TH.

Opium Consumption in India.

Major GRAHAM POLE asked the Secretary of State for India whether the six inquiries instituted by the local governments concerned to inquire into the high consumption of opium in certain areas had been completed.—Mr. WEDGWOOD BENN replied: All but one of the inquiries have been completed.

Artificial Limb Fitting Centre.

Viscount ELMLEY asked the Minister of Pensions whether the artificial limb fitting centre now situated at Norwich would be transferred to Cambridge.—Mr. F. O. ROBERTS replied: Transfer of the centre referred to in due course is contemplated; Cambridge being the most central and convenient point in the area supplied by this centre.

Final Pension Awards.

Sir GEORGE BOWYER asked the Minister of Pensions in how many cases during the last five months pensions had been re-awarded on the ground that final awards should never have been made.—Mr. F. O. ROBERTS replied: Precise statistics are not available for broken periods, but I understand that the number of cases in which further awards have been made during the five months referred to is about 500.

River Pollution.

Rear-Admiral BEAMISH asked the Minister of Agriculture if the draft Report on river pollution had now been considered by the Standing Committee; and when the issue of the Report might be expected.—Mr. BUXTON replied: A draft report will be circulated this week to the members of the committee for their consideration. The Report will be published as soon as possible after it has been approved by the committee.

National Radium Trust.

Sir KINGSLEY WOOD asked the Minister of Health the amount of money expended to date by the National Radium Trust for augmenting the supply of radium for use in the treatment of the sick.—Miss LAWRENCE, Parliamentary Secretary to the Ministry of Health, replied: No disbursements have yet been made, but arrangements are being completed which will result in a considerable augmentation of the supply of radium during the present month.

Artificial Silk Manufacture and Public Health.

Mr. KELLY asked the Minister of Health whether reports had been received from areas in the neighbourhood of artificial silk factories as to the effect on health of the manufacture.—Miss LAWRENCE replied: Reports have been received from districts in which there are artificial silk works. These are substantially in accord with the views expressed in the Report of the Chief Alkali Inspector, to which reference is made in my reply of July 25th last to a question.

TUESDAY, NOV. 5TH.

Care of Mental Defectives in Kent.

Mr. ALBERY asked the Minister of Health what accommodation existed in Kent for the care of mental defectives and the number in such institutions on the last available date.—Mr. GREENWOOD replied: The following accommodation in the County of Kent, excluding the County Borough of Canterbury, is certified or approved for the reception of mental defectives at the instance of the Kent County Council:—

—	Defectives over age 16.	
	Male.	Female.
Cranbrook P.L.I. ..	10	20
Dover P.L.I.	—	6
Eastry P.L.I.	20	24
Malling P.L.I.	—	14
Sevenoaks P.L.I. ..	10	20
Tenterden P.L.I.	—	118*
Tonbridge P.L.I.	40 males under 16.	
Totals..	Over 16: 40 males, 136 females. Under 16: 40 males, 66 females.	

* 66 under and 52 over age 16.

There are two further institutions for defectives within the county: (1) Princess Christian's Farm Colony at Hildenborough, Kent, for 71 male and 68 female defectives; but it is conducted by a voluntary body, and the Kent County Council receives no preference in the allocation of vacancies. (2) Darenth Training Colony, Dartford, an institution of the Metropolitan Asylums Board, but all future vacancies will be filled by cases arising in the London County Council area. The Kent County Council have purchased an estate known as Leybourne Grange, on which they propose to develop a colony for mental defectives. At present the mansion is being adapted for the accommodation of about 90 female patients. On Jan. 1st last the Kent County Council was responsible for 580 mental defectives in institutions or on licence therefrom. The return then furnished did not differentiate between cases detained in institutions in Kent and elsewhere, but I am informed that many Kent cases are sent on contract to voluntary institutions outside the county, and that 261 of the 580 patients were detained in institutions of the Metropolitan Asylums Board.

Shipbreaking Workers and Lead Poisoning.

Mr. WATSON asked the Home Secretary what precautions, if any, were taken by the Alloa Shipbreaking Company at Rosyth to safeguard the health of the workers engaged on burning against the dangers of lead poisoning.—Mr. CLYNES replied: It appears from a report by one of the medical inspectors of factories who recently visited these works that this company devote great care to the prevention of lead poisoning. A doctor has been appointed to give medical supervision, and arrangements are made to transfer to other work burners who show signs of contracting, or being specially liable to, the disease. Steps are also taken to see that so far as possible men do not work in such a position as to be exposed to fumes from another burner. I am advised that there must necessarily be some risk of lead poisoning in this process, but the firm appear to be doing their best to reduce it to a minimum; and I am glad to say that the incidence of lead poisoning at the works has considerably decreased.

The Government and High Milk Prices.

Mr. WISE asked the President of the Board of Trade what action he proposed to take in view of the high cost of distribution of milk and of the disregard shown by the traders of the views expressed by himself and by the Food Council.—Mr. W. GRAHAM replied: The Government have considered the position of the Food Council with particular reference to the recent refusal of London milk distributors to conform to the Council's recommendations as to the retail price of milk in August last. I should like at the outset to state that the Government fully recognise the value of the work done by the Food Council, notwithstanding that since its inception in 1925 it has had no statutory basis and has been without power to require the production of information when it was not forthcoming voluntarily. I may add that neither the Food Council nor any other body has power to compel the observance of the Food Council's recommendations. In the opinion of the Government this position is highly unsatisfactory, and we intend to submit proposals to alter it early next year. The Government are of opinion that the interests of the consumer demand that investigation should take place not only in regard to foodstuffs, but also in regard to other necessaries of life. With this object in view, we propose to ask Parliament to set up a Consumers' Council which shall have power to obtain compulsorily any information that it may require for the purposes of its inquiries. The Government intend also to submit proposals enabling them to deal with trading interests which refuse to accept the views which the Government may reach after considering the recommendations of the Consumers' Council. As I have already indicated, it must be some months before the Consumers' Council can be set up. I am therefore asking the Food Council to remain in being for the purpose of carrying out investigations into such food questions as may arise meantime.

Obituary.

NINIAN McINTYRE FALKINER, M.D. DUB., F.R.C.P. IREL.

THE death of Dr. Ninian Falkiner occurred, after a short illness, on Oct. 30th, at the age of 74. Though his health had been unsatisfactory for some months past he was going about until ten days before his death.

Ninian Falkiner was educated at Trinity College, Dublin, and the Carmichael School of Medicine, and graduated as M.B. in 1884. He became a Fellow of the Royal College of Physicians of Ireland in 1891, and took his M.D. degree in 1900. He spent several years as a poor-law medical officer in the city of Dublin, until in 1900 he was appointed as medical superintendent of statistics in the General Register Office. He held this post for some 20 years, until he was retired on reaching the age-limit. He was for a term Vice-President of the Royal College of Physicians of Ireland, and served as examiner both in that College and in Trinity College. He was also lecturer in Vital Statistics in Trinity College.

A colleague writes of him that he was one of the most modest and self-effacing of men. "He never sought prominence, but he carried out any duties confided to him with a punctilious care. Seeking nothing for himself he was unwearied in finding opportunities for kindness to others. He never was known to utter an unkind word of others, and one cannot believe that he ever conceived an unkind thought. His memory will long be pleasant to all who knew him."

ANTONIUS JOSEPH MANASSEH, B.SC. LEEDS, M.R.C.S. ENG.

DR. A. J. Manasseh, who died on Oct. 31st, had been superintendent since 1898 of the Friends' Missionary Hospital at Brummana, on the slopes of Mount Lebanon. Born at Beirut in 1866, he was of Syrian parentage, and was brought up in the Orthodox Greek Church. He was educated at the High School of the Society of Friends at Brummana, under Theophilus Waldmeier, founder of the Lebanon Hospital for the Insane. He studied at the Syrian Protestant College, Beirut (now known as the American University), and later came to England for his medical training. He took the degree of B.Sc. at the University of Leeds, and after studying at the London Hospital qualified in 1897, later proceeding to the M.D. degree of Constantinople. He was accepted as a missionary of the Friends' Foreign Mission Association in 1897, and after a year's work in Syrian villages he became superintendent of the Quaker medical work at Brummana. In Syria he built up a wide reputation as physician and surgeon, and patients came to him from all over the country. In 1915 he was taken into the Turkish Army as a medical officer, and after being stationed at Damascus, in charge of the typhus hospital there, he was moved to the military hospital at Baalbek, and then advanced to a field hospital at Toul Kerum. There he was taken prisoner by Allenby's army, in September, 1918. He was given medical work in charge of a prison hospital by the British, but was soon released and joined the relief unit of the Syria and Palestine Relief Fund. Although suffering bad health from his experiences, he refused to take any furlough until he had been able to meet the heaviest demands of the relief work. He has since worked at Brummana, where, at the time of his death, he was superintending the building of a new hospital.

"Last spring," writes Dr. Fortescue Fox, "I had the privilege of spending some hours with Dr. Manasseh at Brummana where he had so long been the leading spirit. We discussed the site on the plan of the new hospital by which he hoped to extend the influence of this medical and educational post in the Lebanon. We went together afterwards to Beirut, and everywhere he was welcomed as much for his presence as his advice. He was a fine example of his countrymen at their best."

In 1899 Dr. Manasseh married Henrietta, daughter of George Benington of Enfield. His widow is left with a son and a daughter.

DONATIONS AND BEQUESTS.—Mr. James Fleming Fyfe Jamieson, of Ruthven, Meigle, Forfar, left £1500 for the endowment of a bed in the View Park Nursing Home, and £5000 for various charitable pruposes.—Mr. William Gilman, of Hazelcroft, Alderley Edge, Cheshire, who left over £141,000, besides personal bequests, directed that failing certain trusts, the residue of the property to be divided as to one-half equally between the Royal Infirmary, Manchester, and the Ancoats Hospital, Manchester, and one-half for such other Manchester charities, hospitals, and institutions, and in such proportions and in such manner as his trustees may think fit.—Mr. Peter Bond Burgoyne, of Broadlands, Ascot, left £1000 to the National Hospital for Consumption, Ventnor.—Mr. Thomas Albert Turner, of Lynwood, Newtown, Montgomery, left £1000 to Montgomery County Infirmary, Newtown, for the endowment fund.—Mrs. Eliza Macloghlin, Wigan, bequeathed a legacy of £10,000 to the Royal College of Surgeons for scholarships to be founded in memory of her husband, the late Dr. E. P. P. Macloghlin, of Wigan.—Mr. James Tivendale Spence, of Halbeath, near Dunfermline, left £1000 to the Royal Infirmary, Edinburgh, and the residue of his trust estate to the Dunfermline and West Fife Hospital.—Mr. Robert Benjamin Field Thornton, of Headfield-road, Savile Town, Dewsbury, left £1000 to the Dewsbury and District General Infirmary to endow a Robert Benjamin Field Thornton bed.—Mrs. Martha Roberta Meharry, of Linden Mansions, Hornsey-lane, London, N., besides other bequests, left £1000 to the Royal Victoria Infirmary, Newcastle-on-Tyne, to endow a bed in King Edward's Ward to be named after her late brother, Dr. W. J. Davison.

Medical News.

UNIVERSITY OF OXFORD.—The following awards have been announced:—Welsh Prize: A. P. Meiklejohn. Theodore Williams Scholarships: A. H. Hunt (Human Anatomy), J. W. Litchfield (Physiology), and J. R. Braybrooks (Pathology). Radcliffe Scholarship in Pharmacology: J. R. Braybrooks and G. S. Grist (equal).

UNIVERSITY OF CAMBRIDGE.—At a congregation on Nov. 2nd the following degrees were conferred:—

M.D.—T. A. Butcher.
M.Chir.—John Gray.
M.B. and B.Chir.—J. St C. Elkington, R. A. P. Gray, Alan Maberly, S. S. Chesser, and J. F. Stent.
M.B.—S. D. Isaacs.
B.Chir.—A. T. Howell and C. E. Donaldson.

UNIVERSITY OF LONDON.—Mr. Edwin Deller, LL.D., previously Academic Registrar, has been appointed to the post of Principal of the University as from Oct. 1st, in succession to Mr. T. Franklin Sibly, D.Sc., now Vice-Chancellor of the University of Reading. In 1920, Dr. Deller was appointed assistant secretary to the Royal Society, but returned to the University in 1921 to take up the post of Academic Registrar. From June, 1928, to February, 1929, he was acting Principal Officer.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—A quarterly Comitia of the College was held on Oct. 31st, with Sir John Rose Bradford, the President, in the chair. The following were admitted Members of the College:—

Ilahi Bakhsh, Thomas Henry Booth Bedford, Howard Bell, Denis Hubert Brinton, Philip Ellman, Ishak Kirolos Gayid, Leslie Wakefield Hale, Isidore Liknaitzky, Michael Malk, Arnold Ashley Miles, Sinclair Miller, Minocher Bamanji Mody, Ganpat Bapun Mohile, John Barrie Murray, John Henry Noble, Henry Edward Nourse, William Frederick Howson Ray, Cuthbert Lawson Stote, Bertrand Edward Tompson, Thomas à Beckett Travers.

Licences to practise were conferred upon 126 candidates (117 men and 9 women) who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

H. S. Atkinson, Oxford and London; G. O. Barber, Cambridge and St. Mary's; E. E. Barnett, London; G. H. Bateman, Oxford and King's Coll.; T. S. Belcher, London; F. Bell, Oxford and St. Thomas's; E. Bellamy, Guy's; J. H. Bentley, Cambridge and Univ. Coll.; J. A. K. Brown, Manchester; W. D. Brown, Cambridge and London; D. R. Buchan, Birmingham; P. C. Chakravorty, Calcutta and Middlesex; G. Clarke, Guy's; J. P. Collinson, Sheffield; S. O. S. Cooke, Middlesex; W. H. O. Croft, Birmingham; J. H. Cyriax, Cambridge and St. Thomas's; H. W. Davies, Oxford and King's Coll.; T. Davies, Cardiff and St. Bart.'s; C. D. D. de Labilliere, St. Bart.'s; H. B. A. R. Densham, Guy's; A. Eckford, Cambridge and Guy's; J. A. Edward, Manchester and St. Bart.'s; H. G. Edwards, Cardiff and St. Bart.'s; Lilian P. Edwards, Royal Free; M. P. Ellis, Univ. Coll.; J. F. Fisher, St. Bart.'s; B. M. Fonseka, Middlesex; A. M. Fratel, Bombay and Durham; L. Gabbe, Cape and Guy's; D. K. Gaitskell, Guy's; H. S. H. Gilmer, Cambridge and St. George's; R. McN. Glover, Cambridge and Westminster; P. E. Glynn, Leeds; C. G. Gordon-Wilson, London; G. H. A. Gruetz, Cambridge and St. Bart.'s; M. B. W. Gray, London; Brynelien Griffiths, Cardiff and Charing Cross; E. Gwynne-Evans, Univ. Coll.; Verna Hockett, Adelaide and Westminster; R. H. Hadley, Melbourne, Y. A. A. Hammouda, Cairo and St. George's; Flora Hargreaves, Univ. Coll.; C. C. Harvey, Cardiff and Univ. Coll.; E. Harvey, Oxford and Middlesex; C. F. Hecker, Adelaide and London; Violet L. de A. Hickson, Westminster; F. K. S. Hirschfeld, Melbourne and London; H. B. Hodson, St. Thomas's; J. Horton, St. Bart.'s; R. H. Hucknall, Birmingham; Mary A. Hughes, Cardiff and Charing Cross; E. F. Hunt, St. George's; C. S. Kah, Cambridge and St. Thomas's; K. S. Keele, Guy's; E. J. Kerr, Birmingham; H. Y. Khwaja, Bombay and London; N. Kramer, St. Bart.'s; M. Lee, Durham and Middlesex; E. E. Lewis, St. Mary's; W. D. Lovelock-Jones, Cardiff and Univ. Coll.; F. T. F. Lutter, Cambridge and St. George's; R. W. McConnel, Cambridge and King's Coll.; E. M. MacLachlan, Guy's; F. N. Marshall, Manchester; Eileen M. Massey, King's Coll.; N. D. Matson, Otago and Charing Cross; E. C. W. Maxwell, Cambridge and St. Thomas's; P. H. Merlin, Birmingham; T. J. Millin, Dublin; C. W. Morley, Cambridge and St. Mary's; I. R. Morris, Cambridge and Guy's; D. P. F. Mulvany, Charing Cross; W. D. Neill, London; J. N. O'Reilly, Oxford and Middlesex; B. W. Paine, Univ. Coll.; E. H. Parkinson, Birmingham; L. H. Peiris, Ceylon and King's Coll.; J. Petro, Cambridge and St. George's; I. E. Phelps, St. Bart.'s; R. F. A. Philpott, Oxford and St. Thomas's; T. B. Pitts, Guy's; F. Pomerantz and E. S. Pope, St. Bart.'s; A. C. Price and N. L. Price, Bristol; S. R. C. Price, King's Coll.; F. S. C. Pritchard, Guy's; C. F. H. Quick, Calcutta and St. Mary's; J. P. Raban, Middlesex; B. Ram, St. Thomas's; J. Richardson, Cambridge and Middlesex; Marjorie E. Roberts, Royal Free; J. A. Rogers, Calcutta and King's Coll.; T. N. Rudd, London; C. R. Salkeld, Oxford and St. Thomas's; L. Savronsky, London; J. G. Scadding, Middlesex; D. Sheehan, Manchester; B. C. Singh, Calcutta and Univ. Coll.; E. Sladen, Middlesex; F. J. G. Slator, Cambridge and Durham; J. H. Smith, Cambridge and St. Thomas's; J. O. Smith, Melbourne and St. Bart.'s; A. Somerville, Sheffield; P. D. B. Spence, Edinburgh and Guy's; F. R. Stansfield, Leeds; J. E. S. Stephens, Cambridge and St. Bart.'s; T. Stephens, Cardiff and London; M. Sternfeld, Freiburg and London; Muriel H. Steven, King's Coll.; G. D. Stilwell, St. Thomas's; H. J. Stracey, Madras and St. Thomas's; B. L. Taneja, Punjab and Guy's; J. M. Taylor, St. Bart.'s; T. H. E. Taylor-Jones, King's Coll.; E. G. Thomas, Cardiff and Univ. Coll.; J. C. T. Tregarthen, Guy's; C. E. H. Turner, London; G. S. Walker, Oxford and Univ. Coll.; C. J. Waring, London; J. H. Watkin, St. Bart.'s; K. Watman, Middlesex; V. W. L. Wells, Guy's; T. H. N. Whitehurst, St. Bart.'s; and T. H. Wilson, St. Thomas's.

Dr. John Hay, Dr. F. E. Fremantle, M.P., and Dr. J. B. Leathes were elected to the Council of the College, and Dr. E. P. Poulton gave faith as an examiner in medicine. Sir Francis Champneys was re-elected a representative of the College on the Central Midwives Board, and Dr. H. Letheby Tidy was elected a member of the committee of management. Dr. Robert Hutchison and Dr. James Collier were elected members of the Mackenzie Mackinnon Research Fund Committee. Dr. J. H. Abram and Dr. A. S. Barnes were re-elected to represent the College on the Court of Governors of the University of Liverpool and the University of Birmingham respectively, while Dr. A. S. Woodwark was re-elected as representative on the Central Council for District Nursing. The President announced that Surgeon-Commander Sheldon Francis Dudley had been appointed Milroy Lecturer for 1931, and that the Jenks Memorial Scholarship had been awarded to Francis Sansome Mitchell Heggs. He also announced that permission had been granted to the Ophthalmological Society to hold a reception at the College on April 3rd next on the occasion of its jubilee, and permission was granted to a request that the Savill Memorial Oration might be delivered at the College. The Registrar announced that Dr. J. W. Springthorpe, of Melbourne, had applied for the restoration of the diploma of Member which he had resigned in 1910.

A communication was received from the Home Office that by an Order of Council made on August 15th, 1929, Part III. of the Dangerous Drugs Act, 1920, has been applied to the esters of morphine and their respective salts, and to any preparation, admixture, and extract containing them. —A communication was also received from the University of Wales announcing that the Advisory Board of Medicine had been recently dissolved.—A report was received from Dr. Fremantle, who had represented the College at the Imperial Social Hygiene Congress held in London in July last, in which he commented upon the increased interest taken by the public in the subjects before the Congress.

Dr. R. A. Young presented reports from the Committee of Management concerning alterations in connexion with the regulations for the First and Final Examinations for the L.R.C.P., M.R.C.S.—Dr. Sidney Phillips presented the treasurer's annual statement of receipts and expenditure, and auditors were re-elected. Dr. Arnold Chaplin stated that among donations to the library during the last quarter was an account of the last illness of the Earl of Beaconsfield in the words of the late Dr. Mitchell Bruce.

After receiving the quarterly report of the examiners for the licence on the examination held in July last, the President dissolved the Comitia.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—Out of 15 candidates entered, the following 8 have passed the final professional examination and have been granted the diploma of L.D.S.:—

George Morton Smith McGibbon, Syed Mohammed Ali, William Ainslie Elder Duncan, Walter Pearson Neilson, Robert Hugh Dewar, John Ellis Sprunt, Thomson Alexander Ferguson, and Donald Forbes Johnstone.

The following passed in the subject of pathology:—

Robert Kirkwood Nicol Clarkson and Robert Pearson Neilson.

UNIVERSITY OF DUBLIN.—On Saturday last Mr. William Pearson, surgeon to the Adelaide Hospital, Dublin, was elected Professor of Surgery in the University in succession to the late Mr. T. E. Gordon.

Mr. Pearson, who is a son of Mr. C. Y. Pearson, for many years Professor of Surgery at University College, Cork, was educated at Trinity College, Dublin, where among other achievements he won the Travelling Prize in Surgery. In 1910 he became a Fellow of the Royal College of Surgeons in Ireland, and in the same year was appointed assistant to the Professor of Surgery in Dublin University. During the war he was for some time engaged in work for the British Red Cross Society in France, and later as consulting surgeon in Sussex. He was twice mentioned in dispatches, and retired with the rank of lieutenant-colonel. Since then he has been surgeon to the Adelaide Hospital, Dublin, and to the University of Pensions Surgical Hospital at Blackrock.

Wellcome Historical Medical Museum.—On Monday, Nov. 11th, at a reception to the Egypt Exploration Society, Mr. Warren Dawson will give an address on Egyptian Magic and Medicine. The reception will be at the Museum at 8.30 P.M.

Hunterian Society.—A meeting of this Society will be held at The Cutlers' Hall, Warwick-lane, London, E.C., at 9 P.M., on Monday, Nov. 18th, when Earl Howe, Mr. E. B. Turner, and Dr. P. B. Spurgin will take part in a discussion on The Doctor and the Motorist.

Society of Medical Officers of Health.—The annual dinner of this society will be held at the Piccadilly Hotel, London, W., on Thursday, Nov. 14th, at 7.30 P.M. (Reception at 7.10.) Tickets are obtainable from the Executive Secretary at 1, Upper Montague-street, Russell-square, W.C. 1.

British Science Guild.—At 4.30 P.M. on Tuesday, Nov. 19th, at the Goldsmiths' Hall, Foster-lane, London, E.C., Sir Walter Fletcher, F.R.S., secretary of the Medical Research Council, will deliver the Norman Lockyer Lecture. His subject will be Medical Research: the Tree and the Fruit, and tickets may be had from the secretary of the Guild at 6, John-street, Adelphi, W.C. 2.

London Irish Medical Golfing Society.—At this society's week-end meeting at Sandwich there were 63 entries for the Canny Ryall Cup, and the winner was E. T. Wright. E. T. McElligott and C. Petit tied for the O'Malley Cup, and Petit won on a replay. For the Lett Cup D. S. Gordon and E. T. Wright tied with E. S. A. Crawford and C. L. Wilson: Gordon and Wright won the replay. The Cahill Trophy was won by D. R. Wheeler, the Captain's Prize by E. T. Wright, the Juniors' Prize by R. L. Rea, the Hidden Nine by D. R. Wheeler, and the Eclectic Competition by W. Calwell and D. R. Wheeler (tie).

College of Pestology.—The annual dinner and ball took place at the Piccadilly Hotel on Nov. 1st. Owing to the illness of the new President, the Duke of Sutherland, the chair was taken by Sir Thomas Horder, who pointed out that the intermediate host between the microbe and the human being was the pest, and that to deal with this intermediary was everybody's business, and therefore nobody's. He related the work of the College to the problem of slum-clearance, for as long as slums existed it was impossible to free the country of pests. The toast of the Society was proposed by Captain W. S. Saunders, M.P., and responded to by Mr. Moore Hogarth, who traced the continued usefulness of the College and declared that we were a bug-ridden country, and that it would be impossible to get all the bugs of the metropolis into a container as large as the Tower of London.

Presentation to Dr. Jane Walker.—A dinner was held at the East Anglian Sanatorium, Nayland, Colchester, on Oct. 24th, to celebrate the seventieth birthday of Dr. Jane Walker, its principal. Dr. G. E. Soltau presided, and Dr. G. H. Metcalfe proposed the toast of Dr. Jane Walker. He said that the sanatorium, which was opened nearly thirty years ago, was known not only in Suffolk and East Anglia, but throughout the world. Dr. Vere Pearson spoke of the vitality and enthusiasm shown by Dr. Walker, not only in her medical work but in her interest in music, literature, and art. The chairman said that many of the former medical residents and matrons had desired to join in giving Dr. Walker a tangible expression of their feelings towards her. She handed a bag of gold from past and present patients and members of the staff of the sanatorium to Dr. Walker.

Finance of the Middlesex Hospital.—The report for 1928, which has just been issued, again shows a considerable expansion of work. At 6271 the number of in-patients treated to a conclusion was an increase of 759, and the average number of occupied beds was 340·18, compared with 329·45 in 1927. The increase is partially accounted for by the provision of facilities at the convalescent home for surgical cases at an earlier stage of convalescence. A decrease in costs has resulted, the average weekly cost of each in-patient having fallen by 1*s.* 7*d.* to £4 15*s.* 1·15*d.*, and the total cost per head from £15 1*s.* 4·40*d.* to £13 0*s.* 8·08*d.* The number of out-patients (52,580) is an increase of 3502. There was a fractional increase in the cost in this department, a greater proportion of the time of the dispensary staff having been required owing to the growth in the number of patients. The larger number of resident patients increased the expenditure by £1096 to £100,068, which the governors regard as very satisfactory in view of the cost of the contributory superannuation scheme. The total income went up from £80,177 to £83,515. The grant from the Hospital Saturday Fund fell from £4475 to £3230. The recommendations of a joint committee of the governors and the medical committee are resulting in better conditions for the nursing staff.

Queen Alexandra's Hospital for Officers.—The tenth annual reunion dinner of this hospital was held on Oct. 30th at the Hotel Cecil, under the chairmanship of Major W. B. Binnie, a former patient. Mr. Herbert Paterson read a message of good wishes from the Princess Victoria; Lord Waring proposed the health of the former patients, and Colonel F. R. Hybart, the senior officer, replied.

University of Birmingham Dental Clinical Board.—Four post-graduate lectures will be given at the Dental Hospital, Great Charles-street, Birmingham, at 5 P.M., on Thursdays, Nov. 14th and 28th, and Dec. 5th and 12th. The first lecture will be by Mr. Harold Round on Fractures of the Jaws. Further particulars may be had from the Clerk to the Board at the University.

A Radium Cancer Clinic.—Lord Moynihan, President of the Royal College of Surgeons, last week opened a radium cancer clinic at Burnley Victoria Hospital, of which Dr. J. H. Watson has been appointed director. It is proposed that the clinic should have 1 g. of radium; the first instalment, already in use, consists of 340 mg.

A Licensed Victualler's Bed.—A bed in the Victoria ward of St. John's Hospital, Lewisham, has been endowed by the Blackheath Division of the Licensed Victuallers and Beersellers' Protection Society.

Presentation to a Medical Man.—Last week a presentation was made to Dr. G. S. Pollard on his retirement, after 23 years' service, as honorary medical director of Paulton Memorial Hospital, near Bristol. He has been a member of the medical staff for 43 years. The presentation, from the members of the medical and nursing staffs and the management committee of the hospital, consisted of an armchair, a cheque, and an album containing the names of the subscribers.

The Royal Family and Hospitals.—On Monday Princess Marie Louise laid the foundation-stone of the new Queen Charlotte's Maternity Hospital at Hammersmith.—Last week Princess Louise, Duchess of Argyll, opened a new isolation hospital (60 beds) which has been built by the Hendon urban council, at an approximate cost of £70,000.—The new X ray department of Wembley Hospital has been opened by Prince Arthur of Connaught. The foundation-stone of the institution was laid exactly three years ago, and the hospital, which cost nearly £30,000, was opened free of debt. The accommodation is already insufficient, and plans are being made for enlargement.—On Thursday in last week the Duke of York opened a new pavilion of Grindon Hall Tuberculosis Sanatorium belonging to the corporation of Sunderland.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Nov. 11th.—5 P.M., War. Paper:—Lieut.-Colonel T. B. Layton: The Surgical Aspects of the Transport of the Wounded.

Tuesday.—5 P.M., Therapeutics. Communication:—Dr. J. H. Burn, Dr. S. Wokes, and others: The Use of Ergot. A discussion will follow. 8.30 P.M., Psychiatry (at the Wellcome Historical Medical Museum, 54, Wigmore-street, London, W.). Presidential Address:—Sir Robert Armstrong-Jones: Superstition.

Wednesday.—5.30 P.M., Surgery: Subsection of Proctology. Pathological Meeting preceded by a discussion on Complications of Operations for Piles, to be opened by Mr. Cecil Rowntree (President of the Subsection). Cases and Specimens:—Mr. Cecil A. Joll: Combined Abdomino-perineal Excision of the Rectum and Wertheim's Hysterectomy for Carcinoma of the Recto-vaginal Septum: Abdomino-perineal Excision of Rectum for Endometrioma. Mr. E. T. C. Milligan: Specimen Illustrating Early Carcinoma of the Colon; Two Cases Illustrating Peri-rectal Swellings. Mr. Lionel Norbury and others will also show specimens.

Thursday.—8.30 P.M., Neurology. Clinical Meeting at the National Hospital, Queen-square, W.C.

Friday.—5 P.M., Balneology. Paper: Dr. G. L. Kerr Pringle. 8 P.M., Obstetrics. Specimens: Mr. Clifford White will show two specimens. Short Papers:—Dr. J. Estcourt Hughes: A Case of Hydatidiform Mole with Multiple Small Syncytial Infarction of the Lungs. Dr. Kathleen Vaughan: Maternal Mortality and its Relation to the Shape of the Female Pelvis. Discussion on the Report of the Departmental Committee on the Training of Midwives. Opener: Dr. Herbert R. Spencer. 8.30 P.M., Electro-Therapeutics. Paper:—Dr. Jessie E. Sheret: Massive Collapse of the Lungs.

BIOCHEMICAL SOCIETY.

Saturday (to-day), Nov. 9th.—2.30 P.M. (In the Department of Physiology, University of Liverpool): 129th Meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Nov. 11th.—8.30 P.M., Discussion on the Relative Value of the Different Methods of Diagnosis in Gastric Disease, to be introduced by Dr. J. A. Ryle, Dr. Harrison Orton, and Prof. E. C. Dodds.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, Nov. 12th.—5 P.M., Dr. G. F. Still: The History of Pediatrics in the Seventeenth and Eighteenth Centuries. (Last FitzPatrick Lecture.)
THURSDAY.—5 P.M., Rt. Hon. H. A. L. Fisher: An Oxford Movement (Lloyd Roberts Lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.
THURSDAY, Nov. 14th.—5 P.M., Mr. R. P. Rowlands: Review of the Surgery of the Gall-bladder and Bile-ducts. (Bradshaw Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.
MONDAY, Nov. 11th, to SATURDAY, Nov. 16th.—MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square. Mon., 5 P.M., lecture by Dr. E. P. Poulton on (1) Treatment for the Common Cold, and (2) Recent Work on Bright's Disease. No fee. Two lectures especially suitable for M.R.C.P. candidates: Tues., 8.30 P.M., Dr. O. L. V. de Wesselow: Diabetes and Insulin. Fri., 8.30 P.M., Dr. Bernard Myers: Purpura and its Treatment.—CHARING CROSS HOSPITAL, W.C. Wed., 2 P.M., Demonstration of Gynæcological Cases by Dr. Everard Williams. No fee.—ST. PAUL'S HOSPITAL, Endell-street, W.C. Fri., 4.30 to 7.30 P.M., Demonstration of Genito-urinary Cases and Cystoscopic Examinations by Mr. W. K. Irwin. No fee.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special Post-graduate Course in Medicine, Surgery and Gynæcology, every afternoon and some mornings for two more weeks.—LONDON LOCK HOSPITAL, Dean-street, W. Post-graduate Course in Venereal Disease. Daily every afternoon and evening. Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Nov. 11th.—10 A.M., Dr Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Sinclair: Surgical Wards.
TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Shaw, Medical Out-patients. 2.30 P.M., Sir Henry Simson: Gynæcological Operations.
WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. Dr. Scott Pinchin: Medical Out-patients.
THURSDAY.—11.30 A.M., Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. Bishop Harman: Eye Department. 2 P.M., Mr. MacDonald: Genito-Urinary Department. 4.30 P.M. (Lecture), Dr. Dowling: Dermatological Operations.
FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Shaw: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.
SATURDAY.—9 A.M., Mr. Vlasto: Throat, Nose and Ear Operations. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Children's Department.
Daily, 10 A.M. to 5 P.M., Medical, Surgical and Special Out-patients, Operations, Ward Visits, Anæsthetic Courses.

SOUTH-WEST LONDON POST-GRADUATE SOCIETY, St. James's Hospital, Ouseley-road, Balham, S.W.
WEDNESDAY, Nov. 13th.—4 P.M., Dr. C. E. Lakin: Demonstration of Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Nov. 11th.—2.30 to 5 P.M.: Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Ear, Nose and Throat Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, Nose, Throat and Ear Clinics. Operations.
FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations. 4.30 P.M.: Demonstration on Practical Neurology by Dr. L. R. Yealland.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Nov. 11th.—12 noon, Dr. Greenfield: Pathology of Nervous System. 2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Mr. Leslie Paton: Affections of Optic Nerves.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Purdon Martin: Tumours of the Cerebral Hemispheres.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Ocular Palsies.
FRIDAY.—12 noon, Dr. Purdon Martin: Anatomy and Physiology of Nervous System. 2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Greenfield: Demonstration of Cerebral and Spinal Tumours.

LONDON SCHOOL OF DERMATOLOGY, 49, Leicester-square, W.C.
TUESDAY, Nov. 12th.—5 P.M., Dr. Wilfred Fox: Nævi.
THURSDAY.—5 P.M., Dr. H. G. Burford: Pathology Demonstration.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
WEDNESDAY, Nov. 13th.—4.30 P.M., Sir Thomas Carey Evans: Stone in the Bladder, with Special Reference to Treatment by Litholapaxy.

KING'S COLLEGE FOR HOUSEHOLD AND SOCIAL SCIENCE, Campden Hill-road, W.
FRIDAY, Nov. 15th.—5 P.M., Prof. V. H. Mottram: Human Nutrition. (Fifth of six lectures.)

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.
MONDAY, Nov. 11th.—5 P.M., Prof. Leonard Hill: Sunlight and Health.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road.
FRIDAY, Nov. 15th.—4 P.M., Mr. W. A. Mill: Acute Suppuration of the Middle Ear.

ROYAL NORTHERN HOSPITAL, Holloway-road, N.
TUESDAY, Nov. 12th.—3.15 P.M., Mr. C. S. L. Roberts: Prolapse in Women.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.
FRIDAY, Nov. 15th.—6 P.M. (at the Medical Society of London, 11, Chandos-street, W.), Mr. Harold Cox: The Multiplication of the Unfit.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 13th.—4 P.M., Dame A. Louise McIlroy: The Influence of Pathology Upon Maternal Welfare.

ROYAL ANTHROPOLOGICAL INSTITUTE.
WEDNESDAY, Nov. 13th.—5.30 P.M. (in the Polytechnic Hall, Great Portland-street Extension), Sir Arthur Keith: Race Building—Past and Present.

ANCOATS HOSPITAL, Mill-street, Manchester.
THURSDAY, Nov. 14th.—4.15 P.M., Mr. P. McEvedy: Diseases of Veins.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Nov. 15th.—3.30 P.M., Mr. H. B. Yates: Dyspepsia of Biliary Origin.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 12th.—4.15 P.M., Dr. T. H. Oliver: Diabetes.
FRIDAY.—4.15 P.M., Dr. H. Herd: Behaviour Disorders of Childhood.

Appointments.

MORTON, E. F., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Topsham District of the County of Devon.

MCMILLAN, A. J., L.R.C.P. Lond., M.R.C.S., Tuberculosis Officer for North Devon.

RATNER, E., M.B., Ch.B. Manch., Assistant Medical Officer of Health, Stockport.

Vacancies.

For further information refer to the advertisement columns.

Altrincham General Hospital.—H.S. At rate of £125.
Barnsley, Beckett Hospital, &c.—H.P. £140.
Barry Surgical Hospital.—H.S. At rate of £200.
Bedford County Hospital.—H.S. At rate of £175.
Birmingham City.—Asst. M.O. £750.
Birmingham, Dudley-road Hospital.—Surgeon. £700.
Birmingham, Queen's Hospital.—Jun. R.S.O. £100.
Birmingham Royal Cripples Hospital.—H.S. At rate of £200.
Birmingham, Highbury Hospital.—Res. M.O. £350–£400.
Blackburn and East Lancashire Royal Infirmary.—Fourth H.S. £130.
Bolingbroke Hospital, Wandsworth Common, S.W.—Res. M.O. £200. Also Clin. Asst. to Ear, Nose and Throat Dept. £100.
Brighton, Hove and Preston Dispensary and Hove Hospital.—Hon. Surgeon.
Brighton, Royal Sussex County Hospital.—Sen. Asst. Path. £350.
Church Army Medical Mission.—Lady Doctor.
City of London Hospital for Diseases of Heart, &c., Victoria Park, E.—Res. M.O. £250. Also H.P. At rate of £100.
Bristol, Stoke Park Colony.—Director of Medical Services. £1200.
Derby County Borough.—M.O.H. £1100.
Durham County Council.—Asst. Welfare M.O. £600.
Elizabeth Garrett Anderson Hospital, Euston-road.—H.P. Obst. Asst. Three H.S.'s. Each at rate of £50. Also Clin. Assts.
Great Yarmouth General Hospital.—Jun. H.S. £125.
Harrogate Infirmary.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.
Hertford County Hospital.—H.P. At rate of £150.
Ipswich, East Suffolk and Ipswich Hospital.—Hon. Ophth. Surgeon.
Ipswich, Heathfields Infirmary, &c.—Asst. Res. M.O. £250.
Islington Dispensary, 303, Upper-street, N.—Asst. Res. M.O. £120.
L.C.C. Mental Hospital Service.—Eighth Asst. M.O. £300.
Leamington Spa, Warneford General Hospital.—Res. H.S. £165.
Leeds General Infirmary.—M.O. in charge of Radium Dept. £800.
Liverpool, David Lewis Northern Hospital.—Hon. Med. O. for Cardiographic Dept. Also Two Jun. Anæsthetists. £75.
Liverpool Royal Babies Hospital, Woolton.—Res. M.O. At rate of £90.
London Jewish Hospital, Stepney Green, E.—Res. M.O. Also Jun. Res. M.O. At rate of £130 and £100 respectively.

London Skin Hospital, 40, Fitzroy-square, W.—Hon. Phys. and Hon. Pathologist.
Manchester City.—Asst. Tuber. O. £650.
Manchester, Salford Royal Hospital.—H.P. At rate of £125.
Mothers' Hospital, Clapton, E.—Hon. Asst. Obstet. S.
National Association for the Prevention of Tuberculosis, 1, Gordon-square, W.C.—Asst. Med. Commissioner. £700.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Northwood, Mount Vernon Hospital.—H.S. for Cancer Section. £200.
Paddington Green Children's Hospital, W.—H.S. At rate of £150.
Queen's Hospital for Children, Hackney-road, E.—Surgeon to Ear, Nose and Throat Dept. Also H.S. At rate of £100.
Radium Institute, Riding House-street, W.—Assistant to Medical Department. £600.
Ross Institute.—Bacteriologist for South Africa.
Royal Chest Hospital, City-road, E.C.—Clin. Assts.
Royal College of St. Katharine, Poplar, E., Maternity and Child Welfare Centre.—Asst. M.O. £1 11*s.* 6*d.* per session.
Royal Free Hospital, Gray's Inn-road, W.C.—H.S.'s, H.P.'s, &c. Each £150. Second H.P. and Obstet. Dist. Asst. £100. Surg. Reg. £200. Half-time Gynæcological Reg. and Med. Reg. Each £100.
St. John's Hospital, Lewisham, S.E.—Phys. to Children's Dept. Also Cas. O. At rate of £100.
St. Peter's Hospital, 74, Vallance-road, Whitechapel, E.—Med. Supt. £900.
Sheffield, Children's Hospital.—H.P. Also Third Res. M.O. Each £100.
Sheffield, Jessop Hospital for Women.—Asst. H.S. At rate of £100.
Sheffield Royal Infirmary.—Clin. Asst. to Ophth. Dept. Also Clin. Asst. to Med. Depts. Each £250. Also H.S. £80.
Sheffield University, Faculty of Medicine.—Lecturer in Pathology. Also Demonstrator in Pathology. Each £500.
Southampton County Borough Isolation Hospital.—Res. M.O. £360.
Southampton, Royal South Hants and Southampton Hospital.—Asst. H.S. and Res. Anæsthetist. At rate of £140.
South London Hospital for Women, South Side, Clapham Common, S.W.—Clin. Asst. 1 gn. per attendance.
West London Hospital, Hammersmith-road, W.—H.P., H.S. Aural and Ophth. H.S. and Asst. Cas. O. Each at rate of £100. Also Asst. Surgeon Dentist.
Windermere, Ethel Hedley Hospital for Crippled Children.—Res. H.S. At rate of £150.
Wolverhampton Royal Hospital.—Asst. Pathologist and Pathological Registrar. £350.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Holyhead (Anglesey), Ryde (Isle of Wight), and at Wokingham (Berks).

Births, Marriages, and Deaths.

BIRTHS.

RUSSELL.—On Oct. 26th, the wife of Dr. N. L. Russell, of "Bredon," Alverstoke, of a daughter.

SHEPPARD.—At Rangoon, Burma, on Oct. 28th, to Edith T. Sheppard (*née* Marshall), M.B., B.S., wife of Lieut.-Col. A. L. Sheppard, I.M.S.—a son.

DEATHS.

GALLIMORE.—On Nov. 1st, at Leam-terrace, Leamington Spa, Thomas Gallimore, L.R.C.P., L.R.C.S., in his 80th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

RADIUM AT NORFOLK AND NORWICH HOSPITAL.—It is stated that two members of the honorary surgical staff of this hospital have privately acquired a small quantity of radium, and that hospital patients are now being treated with it.

LONDON VOLUNTARY HOSPITALS.—King Edward's Fund has issued a review of the work and finance of 136 London hospitals in the last five years, which shows an increase during the period of 14 per cent. in the daily average of in-patients, of 11 per cent. in out-patients, and 20 per cent. in out-patients' attendances. At the end of 1928 there were 15,640 beds, or 1600 more than when the Voluntary Hospital Committee made its inquiry in 1924. The total income in 1927 of £3,267,000 rose in 1928 to £3,424,000. To this must be added £978,000 received for endowment and building, making a total for 1928 of £4,402,000 for all direct hospital purposes. Subscriptions and donations have largely increased during the five years, and patients' payments have reached a higher total in each year. The compilers of the review say that so far from the voluntary hospitals "fighting a losing battle," the very opposite is the truth, the statistics showing that they are strengthening their hold upon the confidence of the public.

Notes, Comments, and Abstracts.

THE LOCAL GOVERNMENT ACT IN RELATION TO VOLUNTARY HOSPITALS.*

BY H. P. NEWSHOLME, M.D., F.R.C.P. LOND.,
MEDICAL OFFICER OF HEALTH, CITY OF BIRMINGHAM.

APART from consultation between local authorities and the representatives of the governing bodies and staffs of voluntary hospitals in regard to the general scheme of transfer of institutions, the Local Government Act contains no direct indication of any repercussion on the position of the voluntary hospital, but the approaching union between poor-law and municipal institutions offers possibilities of mutual assistance, coöperation, and coördination between the municipal and the voluntary hospitals. I am not an advocate of the municipalisation of the voluntary hospital. The Local Government Act cannot conceivably have any such result, even remotely. The ideal should be the concurrent maintenance of voluntary and municipal institutions under conditions of friendly association, allowing each to learn from, and to coöperate with, the other

Hospital Officers.

Administrative.—The first essential for coöperation is community of knowledge and of interests, and readiness to exchange information in ways free from the stiffness of officialism and the diplomatic implications of official conversations. The Incorporated Association of Hospital Officers should form an admirable channel for this if its membership could be extended to include the officers of municipal and poor-law hospitals.

Social Workers.—The hospital almoner is found on the staff of some, but not all, voluntary and public hospitals. Her work is profoundly important for the effectiveness of the hospital, both by probing into and remedying domestic hindrances to recovery, and by maintaining supervision after discharge from hospital, as well as protecting the hospital finances. I look forward to the day when every hospital will have its social service section represented by an almoner's department. By the pooling of information through personal contact, as well as by the free discussion of principles and procedure, there should be established a great network of social service in relation to the cure of disease, corresponding with the great network of social services which public authorities have established for the prevention of disease. That correspondence should, in its turn, pass into a further stage of close linkage between the two. I should, for example, like to see the almoner's department making use of the unrivalled knowledge of the local authority's health visitors about the home conditions, difficulties, and idiosyncrasies of the working classes, to maintain a degree of after-care which is at present impracticable.

Nursing Staff.—We are all competing keenly against each other in seeking candidates to be trained as nurses in our several institutions, and that competition at present implies a good deal of waste and duplication of effort. I should like to see the day when our institutions, voluntary and municipal, will collaborate rather than compete in evolving a scheme, first of joint training for the preliminary knowledge which all require, and then of interchange of nurses, which shall make fuller and more even use of the magnificent facilities for all-round training which such a pooling would imply. The difficulties, both personal and administrative, of evolving such a scheme on any large scale are obviously enormous. If, however, the present shyness of entering the nursing services should increase, sheer necessity may one day drive us to the necessary degree of inventiveness. It is possible that a scheme for the training of nurses might be evolved on lines somewhat analogous to those followed by the training of medical students, with perhaps one or more central hostels into which would be drafted the probationers for the various hospitals coöperating in the scheme. Whether those probationers would be selected in the first instance by the matrons of the several institutions individually or coöperatively, or in some other way, would be a matter for consideration. In such hostels the probationer would receive the preliminary training common to all nursing institutions, and would then be detailed to one or other of the coöperating institutions to continue her training. Whether and to what extent a system of exchange of nurses between one institution and another would be practicable is not a point into which I can enter. Such a scheme would only be an extension of arrangements which are already in effect for individual institutions.

---

* Substance of a paper read before the Midland Branch of the Incorporated Association of Hospital Officers at Birmingham on Oct. 24th, 1929.

Use of Hospital Beds and Out-Patient Departments.

It is possible to visualise a number of directions in which coöperation would be useful in the allotment of hospital beds. For example, it would be of value to any given hospital to know what medical, surgical, and special department accommodation is available at any given moment at other hospitals in the same area. It is conceivable that a central information bureau, receiving regular and frequent information—say twice a day—might be a source of convenience for all hospitals. Such a bureau might with advantage develop into a central clearing-house for the purpose of minimising the long periods of waiting for admission to particular hospitals. This problem of the long waiting-list is one of immediate practical importance. I do not anticipate that we are likely to see any radical alterations in our present arrangements for the interchange of patients between hospital and hospital. It may well be considered, however, whether the duplication of special departments on a large scale in general hospitals is as desirable as the alternative of making use to a greater extent of the corresponding special hospitals, and of maintaining at the general hospitals only small special clinics for consultation purposes rather than *for systematised* and detailed treatment. *In some directions*, —e.g., in the use by agreement of some particular hospital for treatment by X rays, instead of the multiplication of X ray treatment plants at a number of hospitals—simplification and saving of expense could result, as well as the ability to provide plant on a scale which is impossible when each hospital attempts to make its own provision.

Hospital beds are to be considered not merely from the point of view of treating patients, but also from that of training medical students. I should like to see the doors of all well-run hospitals, general and special in areas serving a medical school, thrown open to medical students under conditions implying systematic instruction in the direction in which the hospital in question is peculiarly capable of enriching the student's experience.

Occasional visits to out-patient departments in various parts of the country leave an impression that there are still faults to be found—long waiting, too casual directions in regard both to procedure and to treatment, and occasionally even cavalier behaviour by both professional and non-professional staff. The cause at present seems to be indefiniteness of control. What is needed is not so much technical knowledge as the acknowledged responsibility of some one individual for securing effective and kindly discipline in the out-patient department. The qualities needed would be those of a competent business man, combined with those of a capable housewife, and mellowed by an imagination quick to grasp the many anxieties and preoccupations of the applicant for help. There should be a possibility of pooling knowledge of the details of working of out-patient departments.

Joint Purchase of Supplies, Joint Laundries Joint Workshops.

There are no doubt two aspects to the question of joint purchase of stores and provisions by a group of institutions. While the joint purchase may readily imply a substantial saving in costs without any necessary loss in quality, it may not meet the special needs or the particular tastes of some of the coöperating institutions. Granted appropriate safeguards in the purchase of particular items, however, there is ground for careful consideration of the policy of joint purchase as already applied, for example, by a considerable combined group of municipal and voluntary hospitals in Birmingham. Joint laundry work is already in force for the municipal hospitals under the Birmingham Public Health and the Maternity and Child Welfare Committees. A case might also be made out for joint workshops for the preparation of a variety of surgical apparatus. With a large enough central workshop it should be possible to deal with the individual varieties of a particular type of appliance most favoured by individual hospitals.

Treatment of Mental Disease.

Scarcely any aspect of medicine is so fundamentally important and so much neglected as the detection and treatment of mental disease at its inception. Every important town should have in connexion with the out-patient departments of most if not all of the larger general hospitals a psychiatric clinic, run in close collaboration with the mental hospitals of the area; associated with this there should be a certain number of beds for the in-patient observation or treatment of appropriate cases. Such provision would immediately attract a class of readily curable patients who at present, and rightly, refuse to regard themselves as insane, and who consequently delay in seeking the all-important treatment which might save them later from a long period of confinement in a mental hospital. It is my earnest hope that some provision may be made on these lines for a very unfortunate and at present greatly neglected section of the population. The provision of such psychiatric clinics at general hospitals would have a profoundly important reverberation on the work of other departments of the hospital. Almost all physical disease has what might be called a mental overlap, an emotional state with a mental sensitiveness which adds greatly to the symptoms and delays recovery. The influence of the psychiatric clinic on the attitude towards disease in medical and surgical wards would tend towards a quicker cure, with less prospect of pronounced relapse or recurrence, for it would help the patient to clear up the mental concomitants of his physical disease. Moreover, it might well be that any tendency towards a return of those mental concomitants, the significance of which the patient had learnt, would tend to make him watchful and eager to seek early treatment.

Measures Towards the Prevention of Disease.

While hospitals, whether municipal or voluntary, have developed to a high degree of efficiency their powers of curing disease, they are at present only in the very early stages of developing a system for the maintenance of health, the prevention of disease, and the prevention of recurrence of cured disease.

(*a*) More specific, detailed, and systematic instructions *could be given to individual patients as to the way in which* they should conduct their lives after discharge from in-patient or out-patient treatment, with a view of minimising the risks of relapse or of progression of disease, and of detecting the further deviations from the normal at the earliest moment. Such advice is given even now, chiefly by ward sisters and resident staff; but it is usually verbal, and therefore too readily misunderstood or forgotten; and it is liable often to be rather casual. Such instructions could be rendered much more effective by a system of after-care.

(*b*) Ill-health has led frequently to degeneration of the patient's habits of body and mind. Patients should therefore have instructions on discharge, by individual tuition, by leaflets, or otherwise, on the bearing of firmly-established mental and physical habits, on stability of character and effectiveness of personality, and the influence of a desultory habit mechanism in rendering character ineffective, and in diminishing social value.

(*c*) Restoration of physical health releases fresh energies for the patient, and unless he is himself made aware of this, and warned of the importance of harnessing these energies to worthy ends, he may turn back to bad habits of body and mind formed during and as a result of ill-health, and may thus use these energies in directions tending to degradation. It may be that the hospital chaplain rather than the lay staff should face this problem; but it certainly should not be left unfaced, and I should not exempt the medical and nursing staff from their share of responsibility. I should like to lay particular emphasis on this need for recognising that the patient is not merely a physical body to be healed, but an individual with a personality whose point of equilibrium must necessarily be profoundly altered by the cure of his body, an individual with as urgent a need for adjustment of his personality to the now healthier body as was previously his need for the cure of that body.

(*d*) In out-patient departments of municipal and voluntary hospitals dealing with mothers and children much more advice could be given on training in habits, on character training, and establishment of mental stability. These are directions in which the modern view of the close interdependence of physical and of mental health require systematic elaboration in hospital practice.

A Problem with Two Faces.

The problem with which we are met—that of facing the ultimate alternatives of absorption into one service, of friendly coöperation between two types of services working side by side, or of rigidly separate services—the problem found in many spheres of individual, social, industrial, political and even religious life. It appears in the antithesis of individualism and socialism, of the small shop and the multiple emporium, of the self-contained business and the large combine, of the individual and the group, of self-expression and group membership, of Quakerism and Catholicism. The system of sharing experience, of socialism, of State service has inherent in it the defect that the individual, protected *as he is from elimination by his* membership of a large system, can subside too readily to a level of easy attainment below his full capacity, if he does not maintain his idealism of aim. The system of standing on one's own feet, of individualism, of the separate independent unit, has equally an inherent weakness. The representative of the system symbolised by the voluntary hospital may be liable to an over-absorption with his own affairs, and unconcern with the difficulties of neighbours, which can lead to a form of selfishness, preventing him from exercising the breadth of influence which might result from a nearer approximation to the system of community of action. We need, therefore, be neither surprised nor troubled at the difficulties experienced in attaining a satisfactory working arrangement between the voluntary hospital unit on the one hand, and the group of State service units on the other. It is a difficulty which in varied disguises is inherent in human nature. As human nature tends when in equilibrium to find a happy mean between the two extremes, so we may expect to find the solution of our particular difficulties.

FIRST-AID TREATMENT OF BURNS BY TANNIC ACID.

PROVISIONAL instructions for applying the tannic acid treatment of burns under first-aid conditions have been drawn up by Mr. W. C. Wilson, author of the green book on this subject (No. 141 of the Medical Research Council Special Report Series), which was summarised in our columns last week. The instructions, which are included as an appendix to the report, have been modified by him in some respects as the result of helpful criticisms made by H.M. Medical Inspector of Mines, and by the professors of surgery at St. Thomas's Hospital and University College Hospital, London, to all of whom the original draft was submitted by the Medical Research Council. It is hoped that these instructions may prove useful, until fuller experience of the method has been gained in mines and other places where burning injuries are not uncommon, and where immediate hospital treatment may be unavailable.

The treatment here described is an emergency first-aid measure to be employed in cases especially where the patient is to be transported subsequently to hospital, and where the circumstances are such that some time—e.g., more than three hours—must elapse before the patient can reach hospital. If speedy removal to hospital is possible, first-aid treatment should be omitted, and the patient dispatched without delay.

A First-aid Unit.

A first-aid unit consists of the following articles:

(1) Two 2-pint enamel measures graduated in ounces.

(2) Two glass rods.

(3) Fifty packets of tannic acid powder; each packet contains 110 grs. of powder.

(4) A bottle containing tablets of corrosive sublimate. Each tablet contains 8·75 grs. Such tablets are stocked by all chemists.

(5) Five dozen packages of sterilised white surgeon's lint; each package consists of a piece of lint covered by a layer of gauze and wrapped in Kraft paper. The lint is in three forms: (*a*) A piece measuring 20 inches by 30 inches; this package is labelled "Trunk." (*b*) A bandage 4½ inches broad by 3 yards long; this package is labelled "Bandage." (*c*) A face-mask measuring 24 inches by 12 inches. In the mask a rectangular opening 7 inches by 1½ inches is cut to expose the eyes, and horizontal slits are cut 3 inches and 3½ inches long as openings for the nose and mouth respectively. The package is labelled "Face."

The unit contains one dozen "Trunk" packages, one dozen "Face" packages, and three dozen "Bandage" packages.

(6) Twelve rolls of white absorbent wool.

(7) Eight dozen gauze (open wove) bandages.

(8) A jar of vaseline and a flat stick for applying the vaseline.

Instructions in the Application of Tannic Acid.

(1) Remove all clothing from the burned area in order to make a rough estimate of the surface extent of the burn. Take great care that the patient does not become chilled.

(2) Do not attempt any cleansing of the burned area.

(3) Make up the tannic acid solution. In 2 pints of water dissolve one tablet of corrosive sublimate and four packets of tannic acid powder. Stir with a glass rod till all powder is dissolved. The solution must be warm when applied, otherwise the patient becomes chilled. This solution is antiseptic. There is no necessity to sterilise measures, glass rods, or powder. The following is a rough guide to the quantities of solution and lint required in the case of a male adult of average size: (*a*) The lint in a package labelled "Trunk" will cover the entire front or entire back of the trunk and requires *one* pint of solution. (*b*) The lint in a package labelled "Bandage" will cover one entire arm, and requires *half* a pint of solution. Two bandages cover one entire leg and require *one* pint of solution. (*c*) The lint in a package labelled "Face" will cover the face, neck, and sides of head, and requires *six ounces* of solution.

(4) According to the surface extent and regional distribution of the burn, select the number and type of packages which [illegible] will provide [illegible]nough lint to cover over the burned area. Remove the lint from [illegible] the packages, soak it in the tannic acid solution, wring out [illegible] gently, and apply the smooth side of the lint to the burned area. The hands should be washed thoroughly with soap and water before the lint is touched. Cover the lint with a layer of wool and fix with a gauze bandage.

(5) Burns of the face. *Take care that no tannic acid solution enters the eyes.*

Protect the eyes in the following way: Tell the patient to close his eyes and keep them closed. With the flat stick smear a *thick* layer of vaseline over the eyelids, eyebrows, and for some distance round the eyes. Cover the vaselined area with wool. Soak the face-mask in the solution, wring out *firmly*, squeezing out all excess solution, and apply to the face, leaving the regions of the eyes, nostrils, and mouth exposed through the openings cut in the mask for this purpose. Secure with a gauze bandage round the head and neck. The openings in the mask can be widened if necessary, or a face-mask can be improvised from a piece of lint in a "trunk" package by making the necessary openings.

Sterilisation and Storage.

(1) *Lint.* The packages with a covering of Kraft paper have previously been sterilised by steam at 15 lb. pressure for 20 minutes and dried. If the packages are kept clean and dry the lint will remain sterile for long periods.

(2) The whole unit is contained in a wooden box, which should be stored in a dry place. The lint packages and packets of tannic acid powder must be kept dry and clean. The packets of tannic acid powder are best kept in a separate tin box with a tightly fitting lid.

ENERGEN FOODS CO., LTD.

WE have received from this company forms of certificate which, upon signature by a medical man, will serve as an authority to any retailer to supply Energen Foods at a *special reduction to the patient while the patient remains under treatment.* The company claim that their wares are now generally recognised by the medical profession as useful in the dieting of diabetic and obese subjects, and those suffering from various digestive disorders, and a reduction of price will bring these foods within reach of panel patients.

JENNER AND THE CANADIAN PIRATE.

UNDER this heading the Hon. William Renwick Riddell, the Canadian Justice of Appeal, contributes an interesting story to the *Canadian Journal of Medicine and Surgery* for October, which shows that vaccination has been beneficent in other directions than that for which the originator of the practice intended it. Some will have heard that Napoleon, when about to refuse a request for the release of certain English prisoners, remarked, on being reminded by Josephine that the petitioner was Jenner, "Ah, we can refuse nothing to that name," and at that time Jenner's fame was great on the continent. In 1803, for example, the King of Spain equipped an expedition intended to diffuse knowledge of vaccination throughout the Spanish dominions in the new world, with the result that the practice spread rapidly; it was owing principally to this that the "Canadian Pirate," Jeremiah Powell, a son of William Dummer Powell, *afterwards Chief* Justice of the Court of King's Bench, Upper Canada, was released from a long term of what would have been practically slavery. The story, as Mr. Justice Riddell tells it, is as follows: Judge Powell married the daughter of one Dr. John Murray of Norwich, who was a close friend of Jenner. Jeremiah was placed by his father in a counting-house in New York, but, being of a restless nature, among other escapades, he took part in an expedition to free Venezuela from Spanish rule. He was captured, and sentenced to ten years' imprisonment in the Castle of Omoa, in the unhealthy province of Mexico, some of his colleagues being executed as pirates. Judge Powell, after an unsuccessful appeal to the Spanish Ambassador for his son's release, sailed to London with the intention of petitioning the King of Spain, and in the meantime had written to his brother-in-law, Charles Murray, in London. Charles Murray at that time had received a letter from Jenner referring to the success of the Spanish venture in vaccination, to which he replied referring to the sentence passed on his nephew, and mentioning the episode of Jenner's success with Napoleon, an episode that seems hitherto not to have been chronicled. He believed that Jenner might "have again the God-like satisfaction of being the means of setting the prisoner free." Jenner accordingly gave Judge Powell letters to the Court at Madrid, in response to which Jeremiah, the "Canadian Pirate," obtained his freedom. This the young man did not long enjoy, for shortly afterwards he was lost at sea, neither ship nor passenger being ever heard of again.

NEW LABORATORIES AT SHEFFIELD.—The students of the University of Sheffield are devoting the proceeds of this year's "rag" to the equipment of the new laboratories which are being erected at the Royal Infirmary.

Schorstein Lecture

ON THE

PRECURSORS OF CARCINOMA OF THE STOMACH.

Delivered at the London Hospital on Nov. 8th, 1929,

BY ARTHUR F. HURST, M.D. OXF., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO GUY'S HOSPITAL.

EVERY year about sixteen thousand people die in Great Britain from cancer of the stomach. It is the cause of death in 5 out of every 100 people dying after the age of 40, and accounts for about one-third of all deaths from carcinoma. Even with the most modern methods of diagnosis the disease is rarely recognised sufficiently early to make it possible for a radical operation to be performed, and up to now treatment with deep X rays and with radium has met with little or no success. It is indeed doubtful whether permanent recovery occurs as the result of treatment in more than 1 or 2 per cent. of all cases of carcinoma of the stomach. So much progress has been made in the diagnosis of carcinoma of the stomach and in the technique of gastrectomy that, if all individuals suffering from suspicious symptoms were thoroughly examined without delay, many more cases could be operated upon with some hope of success. But even in the hands of the most experienced and skilful surgeons the prospects of cure would remain comparatively poor, so insidious is the onset of the disease, and so latent does it remain in its early stages.

It is clear that it is to prophylaxis rather than to improved methods of diagnosis and treatment that we must look for any real diminution in the high death-rate from carcinoma of the stomach. In my opinion such prophylaxis is possible, because I believe that carcinoma never *invades a healthy stomach*.

The actual development of carcinoma must, I suppose, be due either to a constitutional and perhaps inherited liability to the disease, or to the chance invasion of the individual by some external stimulant, as otherwise it would be impossible to explain why everybody suffering from the disorders of the stomach which predispose to malignant disease do not develop cancer. But until something is discovered which may make it possible to deal with this unknown exciting factor, our attention should be concentrated on the recognition and adequate treatment of the predisposing conditions. If this is done, I feel confident that the incidence of carcinoma of the stomach will in the next few years be greatly reduced.

I propose to approach the subject from a clinical standpoint before discussing the pathological evidence, because it was a study of the results of our clinical investigations in a series of cases of carcinoma of the stomach, undertaken in the preparation of a paper on the early diagnosis of carcinoma of the stomach for the International Conference on Cancer held in London last year,[1] which led me to the conclusions which I summarised on that occasion and which I propose, in the light of further experience, to discuss to-day.

ACHLORHYDRIA.

Fifty years ago van den Velder[2] discovered that carcinoma of the stomach is often associated with the complete absence of free hydrochloric acid from the gastric contents. Using the Ewald test-meal it was subsequently found that achlorhydria was present in about 80 per cent. of cases. The introduction of the fractional test-meal by Rehfuss in 1914 made is possible to recognise the presence of small quantities of free hydrochloric acid at one or more stages of digestion, which would have been missed by a single intubation. When this method was used, complete achlorhydria was found in only 50 per cent. of cases from the Mayo Clinic collected by Hartman[3] and in 65 per cent. of 74 cases at Guy's Hospital and New Lodge Clinic.

It has always been assumed that the achlorhydria is a result of the carcinoma, although none of the numerous theories which have been proposed to explain its occurrence appeared to be satisfactory. A study of the data obtained in our cases, and of those published by other investigators, has convinced me that this assumption is unjustified, and that the achlorhydria is a result of chronic gastritis, which precedes the onset of the carcinoma, and is in fact the most common predisposing condition.

I have never seen a case of carcinoma in which free hydrochloric acid was present at an early stage and disappeared as the disease advanced. I have also been unable to discover a single record of such a case, and not one of the numerous physicians with whom I have discussed the question has ever made such an observation. I have seen three cases of gastric ulcer in which a test-meal was given both before and after the onset of malignant degeneration. Hyperchlorhydria was present in two, and a normal curve of acidity was obtained in the third; in each case the degree of acidity was undiminished when the carcinoma had developed. The following is the history of the first case.

Carcinomatous Degeneration of Chronic Gastric Ulcer whilst under Observation.—A man of 66 had had typical symptoms of gastric ulcer for four years. On admission to New Lodge Clinic on Feb. 23rd, 1924, the diagnosis was confirmed by the discovery with the X rays of a large crater on the lesser curvature; this was associated with hyperchlorhydria and the constant presence of occult blood in the stools. He was given the usual treatment, and all symptoms disappeared within a week. He returned for re-examination on April 11th and again on May 18th; the X rays showed that the crater was much smaller, but as occult blood was still present I advised a continuation of strict treatment. He returned for the third time on June 22nd. He felt and looked strong and well, had gained 6 lb. in weight since his first admission, and had had no trace of indigestion. At this stage I thought that the small deformity still seen with the X rays must represent the scarred depression in the pancreas produced in the healing of the ulcer. Everything else seemed so satisfactory that I did not feel justified in advising operation simply because a trace of occult blood was still present in the stools.

Early in August, for the first time since the commencement of treatment, he experienced pain; it was quite different in character from the old ulcer pain, and was accompanied by nausea and anorexia. No relief followed careful dieting, and he returned to the clinic on August 31st. He had gained another 4 lb. in weight since June. Nothing abnormal was felt on abdominal examination. Occult blood was still present in the stools, and a most remarkable change had taken place in the X ray appearance in the nine weeks which had elapsed since the last examination. Instead of a very small niche with a smooth outline there was a large irregular deformity which was unmistakably due to malignant disease. The hyperchlorhydria was still present in undiminished degree.

A few days later Mr. L. Bromley performed a partial gastrectomy. A large thick scar was found on the lesser curvature, its centre forming a smooth-walled depression in the pancreas. Microscopical examination showed that carcinomatous changes were occurring on one side of the scar, and that the neighbouring mucous membrane was becoming infiltrated. There were no enlarged glands or secondary deposits. In spite of radiotherapy signs of recurrence appeared seven months later.

There can be little doubt that the persistent occult blood was due to the fact that malignant degeneration had already begun in March or April, probably before the ulcer had completely healed. This sign, therefore, preceded the earliest symptoms by five months and the earliest radiological changes by at least three months, and no diminution *in gastric secretion* had occurred in six months.

Mr. A. J. Walton[4] has stated that he has observed the acidity diminish when a chronic gastric ulcer became malignant. He tells me, however, that on re-examining the data which led him to make this statement, he discovered that the observations had been incorrectly recorded, and that he has as a matter of fact never observed such an occurrence.

I only know the history of two cases in which a test-meal had been given before as well as after the development of carcinoma of the stomach associated with achlorhydria, and in both achlorhydria was already present on the first occasion.

In February, 1905, Alexander[6] was consulted by a man of 47, who gave a two years' history of epigastric discomfort and nausea; he was found to have achlorhydria, but no other evidence of organic disease. He derived some benefit from the administration of hydrochloric acid. In April, 1908, he began to have severe pain, and in May was found to have an inoperable growth of the stomach.

I am indebted to Dr. R. A. Veale for the notes of the second case.

A woman of 62 complained of fullness and burning after meals; in June, 1920, she was found to have achlorhydria with excess of mucus. Two years later a dull continuous pain and anorexia developed, and she became progressively more pale; in February, 1920, achlorhydria was again present, but an inoperable carcinoma of the pyloric end of the stomach was found on exploration.

Porges[7] states that he has seen cases in which achlorhydria was found to be present many years before the appearance of symptoms of carcinoma.

In a large proportion of cases of carcinoma of the stomach, which show unmistakable pathological evidence of being secondary to a chronic ulcer, free hydrochloric acid is found. This fact was noted as long ago as 1890 by Hauser[8] and 1903 by Riegel.[9] Free acid was present in my three cases referred to above, and in the only one of Stewart's ulcer-cancer cases, in which a fractional test-meal was given, a high normal curve of acidity was obtained.[10] In 12 out of 14 operative cases of definite ulcer-cancer described by Orator[11] free hydrochloric acid was found with an Ewald test-meal; it is not unlikely that a fractional test-meal would have revealed the presence of free acid in one or more fractions in the two remaining cases. On the other hand, achlorhydria was found in 7 out of 8 cases, in which the carcinoma appeared to be "primary."

Using a fractional test-meal free hydrochloric acid was found in all but one of 11 Guy's Hospital and New Lodge Clinic cases of carcinoma of the stomach with more than 18 months' history, whereas 17 out of 19 with a history of less than six months had achlorhydria.

TABLE I.—*Length of History (24 N.L.C. and 14 Guy's).*

No. of cases.	Free HCl in fractional test-meal.	Less than 6 months.	6–18 months.	18 months and over.	Average (excluding*).
14	Present.	2 (5/12; 6/12)	2 (10/12; 12/12)	10 (1½, 1½, 1½, 2½, 3½, 4, 4, 12, 12, 30 years*)	3 years.
24	Absent.	17	6	1 (20 years*)	9 months.

Most of the former were presumably cases of ulcer-cancer and of the latter "primary" cancer. In 1911 Panton and Tidy[12] had obtained similar results with the less accurate Ewald test-meal; they found that 20 out of 25 cases with a history of nine months or less had achlorhydria, whereas 4 out of 5 with a history of more than two years had free acid present. Stewart[10] found tha tthe average duration of symptoms in 11 cases of definite ulcer-cancer was 6½ years or only a year less than the average duration of symptoms in a contemporary series of 146 cases of simple gastric ulcer, whereas in 48 cases of "primary" cancer it was one year, and in 10 out of Orator's[11] 16 cases of ulcer-cancer symptoms had been present for periods varying between 1 and 28 years, whereas in 5 out of 7 cases of "primary" cancer there was less than a year's history. It seems clear therefore that when free acid is present the carcinoma is likely to be secondary to ulcer, and when achlorhydria is present it is generally secondary to gastritis. Thus achlorhydria is not a sign of advanced carcinoma, in the early stage of which free acid was present, as the duration of symptoms would then tend to be considerably shorter when free acid is present than in cases with achlorhydria, whereas the reverse is actually the case.

It is natural that there should be exceptions to the general rule as to the association of free acid with ulcer-cancer and achlorhydria with gastritis-cancer, and to the relative duration of symptoms in cases with free acid and with achlorhydria. Thus achlorhydria may occur in very chronic cases of ulcer owing to secondary gastritis, and gastritis does not invariably lead to the complete disappearance of free acid from the gastric contents. Moreover, gastric ulcers are occasionally latent for long periods, and chronic gastritis, though generally latent, sometimes gives rise to definite gastric symptoms.

If achlorhydria was a result of the development of carcinoma in a stomach which had previously secreted a normal gastric juice, the prospect of survival after operation would be considerably better in those cases in which free acid was present than in those with achlorhydria. This, however, is not the case, as on analysing the results of operation five years after gastrectomy had been performed for cancer of the stomach, Hartman[3] found that 44 per cent. of 30 patients who had had complete achlorhydria were still alive, compared with only 22 per cent. of 41 with free hydrochloric acid. These figures strongly support the view that achlorhydria precedes the development of carcinoma and is not its cause.

CHRONIC GASTRITIS.

Under normal conditions the food is finely divided, softened, diluted, and brought to the body temperature in the mouth, so that any irritation which it might exert on the gastric mucous membrane as a result of its physical and chemical properties is, to a large extent, prevented. When, however, food is insufficiently prepared, owing to bolting or inadequate teeth and dentures, the stomach is called upon to carry out the neglected functions of the mouth in addition to its normal functions of digesting proteins. In the process of breaking up, softening, diluting, and warming cold or cooling hot food, in order that the insufficient preparation in the mouth should not interfere with intestinal digestion, the mucous membrane of the stomach is irritated and excess of protective mucus is secreted by the superficial cells of the mucous membrane. If long continued this irritation may eventually give rise to catarrhal gastritis, especially if the quantity of gastric juice secreted is less than the average. It is clear, for example, that the effect of strong alcoholic drinks taken apart from meals will be particularly deleterious in an individual with a stomach which habitually secretes a small quantity of gastric juice. Thus constitutional hypochlorhydria and the constitutional achylia gastrica, which occur respectively in about 8 and 4 per cent. of normal individuals (Bennett and Ryle)[13] predispose to chronic gastritis, whereas constitutional hyperchlorhydria tends to prevent its development.

Chronic catarrhal gastritis is characterised by the continuous secretion of mucus in excess of that normally called forth in response to temporary irritation. This tends to form a tenacious layer which adheres to the surface of the mucous membrane, as can often be demonstrated post mortem. Consequently the mouths of the gastric glands are blocked, and the gastric juice, which the still undamaged glands secrete, is unable to reach the lumen of the stomach; at the same time the raised pressure in the ducts must result in the inhibition of further secretion. If any juice still enters the stomach some or all of the free acid combines with the mucus. Knott[15] has shown that the resulting acid-albumin does not activate pepsin and exerts no destructive action on bacteria.

A vicious circle is now set up. Owing to the diminution or complete disappearance of the gastric juice the food is no longer softened and diluted in the stomach, so that any mechanical or chemical irritants it may contain still further damage the mucous membrane. The churning movements of the stomach break up the food less efficiently, as the connective tissue of meat and the cellulose of vegetables remain unsoftened. At the same time the antiseptic barrier normally offered by the acid of the gastric juice is lost. Streptococci from septic teeth, tonsils, and nasal sinuses flourish in the neutral or slightly alkaline contents of the stomach and invade the intestines, and Knott[16] has shown that the increased alkalinity of the contents of the small intestine, which occurs when little or no free hydrochloric acid enters the duodenum, results in the invasion of the small intestines and stomach with the colon bacillus. The mucous membrane of the stomach is now attacked by organisms, especially streptococci, and a true infective gastritis develops.

In the earlier non-infective stage the chronic catarrh is little more than an exaggeration of the normal secretion of mucus which occurs in response to the application of mechanical and chemical irritants, only the superficial parts of the mucous membrane being involved. The infective gastritis, on the other hand, leads to progressive damage of the secreting tubules; the mucous membrane which is at first thickened finally becomes atrophied, and the cells which produce hydrochloric acid and pepsin are gradually destroyed, so that true achylia results. Complete recovery from the early catarrhal gastritis with a return of normal secretion occurs if the irritation is discontinued and the mucus is washed away, but the atrophy of the secreting tubules which results from the later infective gastritis and the consequent achylia are irrecoverable.

Chronic gastritis may also be a sequel of the acute gastritis caused by food poisoning. I have seen several cases in which the history clearly pointed to such an origin, and in the rare instances in which we have had an opportunity of examining patients within a few weeks of the acute attack we have found that no free hydrochloric acid was present in the stomach, but that there was a great excess of mucus and often more or less blood, which only very slowly disappeared. In the Schorstein Lecture of 1927 Faber[14] described the chronic gastritis which may result from general infections, such as the acute fevers and tuberculosis. I have certainly seen cases in which it appeared to be a sequel of an attack of influenza, in which abdominal discomfort and vomiting were prominent symptoms. I am convinced that so-called gastric influenza represents a definite clinical condition, in which the resulting chronic gastritis and achlorhydria may be the starting-point of a variety of secondary disorders, the connexion of which with influenza has in the past frequently been regarded as imaginary.

Chronic gastritis with complete achlorhydria is often completely latent; probably the majority of cases give rise to no symptoms of any kind. It may, however, be the direct cause of nausea and vague gastric discomfort, though it never gives rise to pain or vomiting, and the gastric symptoms are rarely sufficiently marked for the patient to seek medical advice for their relief. Symptoms are more often due to the secondary effect of achlorhydria on some other organ than to the gastritis itself. Thus it is the most common of all causes of chronic diarrhoea. The achlorhydria which is an essential predisposing cause of the Addison's anæmia-subacute combined degeneration of the spinal cord-Hunterian glossitis syndrome, is, as I have shown elsewhere,[17] almost as often the result of chronic gastritis as of constitutional *achylia gastrica. It is also an important* factor in the production of all intestinal infections, chronic appendicitis and cholecystitis, and less frequently of rheumatoid arthritis and other general disorders.

Until recently our knowledge of the pathological anatomy of chronic gastritis was very deficient owing to the rapid post mortem changes which take place in the mucous membrane, although Faber's method of injecting formalin into the stomach immediately after death yielded important results. During the last few years a number of German pathologists have made a special study of the whole of the mucous membrane of specimens obtained by very extensive, though generally incomplete, gastrectomy performed for chronic ulcer and carcinoma. They have shown that in all cases of carcinoma gastritis is present. In those cases in which it appears to be "primary," well-marked atrophic gastritis is present throughout the stomach, whether the growth is small or widespread. Thus Orator[18] found diffuse, generally atrophic, gastritis involving the fundus as well as the pyloric region in 19 out of 20 such cases; in the remaining case, one of pyloric cancer, there was a very long history of alcoholic gastritis, but most of the mucous membrane of the fundus, though slightly inflamed, was not atrophic. On the other hand, although there was well-marked gastritis in the pyloric region in each of his eight cases of definite ulcer-cancer, in five the mucous membrane of the fundus was perfectly healthy, in two it showed slight gastritis, and in only one was severe gastritis present. Konjetzny,[18] Faber,[14] and others have shown that more or less localised gastritis is present in all or almost all cases of chronic ulcer, which explains its association with ulcer-cancer. This makes the presence of universal atrophic gastritis in cases of so-called "primary" carcinoma all the more significant. It seems clear in fact from the clinical and pathological evidence that the carcinoma is no more primary than in the ulcer-cancer cases, but is secondary to the gastritis, so that this form of cancer of the stomach should be called gastritis-cancer in contrast with ulcer-cancer which is due to malignant degeneration of a simple ulcer.

CHRONIC GASTRIC ULCER.

The difficult question of the development of carcinoma from simple ulcer of the stomach has been very thoroughly investigated by Stewart,[19] and I cannot do better than quote his conclusions in his own words.

> "In my series of 259 specially studied operation specimens there were 11 which, in my opinion, fulfilled all the criteria, both anatomical and clinical, of ulcer-cancer. The results are shown in Table II.

TABLE II.—*Frequency of Ulcer-cancer (Stewart).*

70 cancers—11 arising in ulcer	15·7 per cent
180 chronic ulcers—11 with cancer in the margins	6·1 ,,

> "These figures for the incidence of ulcer-cancer are rather lower than those previously published from Leeds[15]—viz., 17·5 and 9·4 per cent. respectively. This is due to the exclusion from the ulcer-cancer group of certain cases, previously included, in which a large part of the floor of the ulcer was cancerous, and in which, incidentally, the clinical history was 18 months or less. In the present series three *of the cases had histories extending over 2½, 3, and 4 years* respectively; all the others had had symptoms for five years or longer. Now it is undoubtedly true that a certain number of cases of chronic ulcer coming to operation give a comparatively short clinical history, while extensive cancerous infiltration of the crater floor does not, of itself, necessarily exclude ulcer-cancer. I am inclined to think, therefore, that if anything these latest figures err on the side of being too conservative; at the least, they must be taken as the absolute minima so far as the present series of cases is concerned."

Further analysis of his figures show a remarkable difference in the liability to malignant degeneration when the common lesser curvature ulcers are compared with the rare prepyloric ulcers. Thus although *only 3 out of 50 of the common carcinomata of the* pyloric region were secondary to ulcer, compared with 8 out of 12 of the comparatively rare lesser curvature carcinomata, no less than 3 out of 9 ulcers in the pyloric region showed malignant changes, compared with only 8 out of 172 in the lesser curvature region. In a similar series of 334 resections for ulcer Orator found 11 out of 34 in the pyloric region showed malignant changes compared with 0 out of 300 in the lesser curvature region.

ADENOMA OF THE STOMACH.

Polypous adenomata were present in 47 out of 11,000 autopsies performed by Stewart[20]; in 27 they were single, in 7 there were two, in 1 three, and in 2 four; in 10 they were numerous. Six of the 27 cases (22 per cent.) with a single polypus and 7 of the 20 with multiple polypi (35 per cent.) were associated with carcinoma. As there were 263 cases of carcinoma of the stomach in the same series, about 5 per cent. of the latter were probably secondary to simple adenomata. This condition seems to be distinct from the very rare polyposis of the stomach, in which hypertrophic gastritis has led to the development of innumerable polypoid masses scattered over the greater part of the stomach. The mucous membrane in this condition, as Menetrier[21] was the first to find out, is also very liable to undergo malignant degeneration.

LOCALISATION OF CARCINOMA OF THE STOMACH.

Although the type of gastritis which predisposes to cancer appears to affect the whole or the greater part of the stomach more or less uniformly, and although a very large majority of chronic ulcers are situated on the lesser curvature of the stomach and in the duodenal bulb, cancer is much more common in the pyloric region than anywhere else in the stomach and it never involves the duodenal bulb. It is clear, therefore, that there must be some other factor predisposing to the development of cancer when the pyloric region is affected by chronic gastritis or by chronic ulceration, which is present to a much less marked degree in the rest of the stomach and is completely absent from the duodenum. This factor is probably friction. When the normal gastric movements are watched with the X rays, it is clear that the mucous membrane of the fundus of the stomach and of the duodenal bulb is never subjected to friction. There is very little friction in the body of the stomach, but it steadily increases in intensity as the pylorus is approached, owing to the increasing depth of the waves of peristalsis, which begin at the junction of the upper and middle thirds of the stomach and only give rise to definite churning movements in the pyloric vestibule. No churning occurs either in the fundus of the stomach or in the duodenal bulb.

ADDISON'S ANÆMIA AND SUBACUTE COMBINED DEGENERATION OF THE CORD.

I have seen three cases of typical Addison's anæmia, one of which was accompanied by subacute combined degeneration of the spinal cord, associated with cancer of the stomach, and several similar cases have been recorded. In commenting on the first of my cases, which was reported by Waterfield[22] in 1923, I suggested that the nervous symptoms and anæmia were a result of the achlorhydria, to which the carcinoma had given rise, although weakness and paræsthesia of the feet were present before any gastric symptoms had developed. Porges[7] mentions a case in which a small, non-ulcerated, carcinoma of the stomach, no larger than a pea, which had given rise to no symptoms, was found at the autopsy of a patient who had died of Addison's anæmia. I now realise that the carcinoma was probably secondary to chronic gastritis, and that the subacute combined degeneration of the spinal cord and anæmia resulted from the achlorhydria which was present before the carcinoma developed. As achlorhydria is an essential predisposing factor in the production of Addison's anæmia and subacute combined degeneration of the cord, it is natural that the latter should be occasionally associated with carcinoma of the stomach, whether the gastritis which precedes its development is the cause of the achlorhydria or is simply secondary to constitutional achylia. It is interesting to note that no case has ever been recorded of the association of Addison's anæmia with a simple ulcer of the stomach or duodenum, as these conditions require the presence of free hydrochloric acid for their development.

ORIGINS OF CANCER: A SUMMARY.

It is now possible to summarise my conclusions as to the origin of an average hundred cases of carcinoma of the stomach.

1. (*a*) In about 75 per cent. of cases the carcinoma is secondary to chronic atrophic gastritis; these comprise a large majority of those with a short history, almost all of those with achlorhydria, and most of those with hypochlorhydria. (*b*) In about ½ per cent. of cases the carcinoma is secondary to polyposis of the stomach, which is probably a result of hypertrophic gastritis. The history is generally long and achlorhydria is probably always present.

2. In about 20 per cent. of cases the carcinoma is secondary to chronic gastric ulcer; these comprise a large majority of those with a long history, all of those with hyperchlorhydria and a high normal curve of acidity, and almost all of those with the average normal acidity.

3. In about 4½ per cent. of cases the carcinoma is secondary to a simple adenoma of the stomach. The history is likely to be short, and there is nothing characteristic about the test-meal.

PROPHYLAXIS.

The ideal form of prophylaxis would be not merely to recognise and treat the common precancerous gastric conditions, chronic gastritis and chronic gastric ulcer, but to prevent their development. The chief exciting causes of the two conditions are identical; the presence of one or other of the predisposing constitutional conditions determines whether either of them should develop. Prophylaxis of this kind is of the simplest nature; prevention of oral sepsis by adequate dental hygiene and frequent and efficient dental treatment; removal of septic tonsils in childhood and the early recognition and treatment of sinusitis complicating such infections as influenza; regular hours for meals and thorough mastication; avoidance of the excess of "roughage" advocated by most up-to-date food faddists; strict moderation in smoking and in the consumption of alcohol.

Theoretically it should be possible to recognise and cure the conditions which predispose to carcinoma of the stomach.

1. *Chronic Gastritis.*

(*a*) *Diagnosis.*—Although chronic gastritis rarely gives rise to gastric symptoms which are sufficiently serious to call for investigation, the associated achlorhydria is often the cause of various other conditions which lead the patient to seek for medical advice. Owing to its frequent association with chronic diarrhœa, chronic cholecystitis and gall-stones, chronic appendicitis, the Addison's anæmia-subacute combined degeneration of the spinal cord, Hunterian glossitis syndrome, and rheumatoid arthritis it is often discovered incidentally when patients suffering from these conditions are investigated with proper thoroughness. It should be remembered that no patient suffering from any one of these conditions can be regarded as "cured" if the end-result is alone treated; a patient with chronic appendicitis or gall-stones, for example, is almost certain to have further trouble sooner or later if his appendix or gall-bladder is removed and the associated achlorhydric gastritis is ignored.

A test-meal should also be given to patients who have had an attack of serious food poisoning or "gastric influenza" associated with abdominal pain and vomiting. By this means it is possible to recognise that form of chronic gastritis which is a sequel of acute gastritis, and which may, if left untreated, give rise to serious trouble later, possibly only after an interval of many years.

When those cases of chronic gastritis which come to be examined on account of gastric symptoms or the presence of secondary conditions and those which are a sequel of acute gastritis are excluded, there must remain a considerable number which are completely latent in their onset and in their course. It is not uncommon nowadays for educated people to ask for a complete physical overhaul from time to time, even when they are feeling quite well. Such a proceeding is very wisely encouraged by certain insurance companies in America. If such an overhaul included a test-meal, the presence of chronic gastritis would be recognised, and steps could be taken to treat it and thus prevent the possibility of the subsequent development of the various conditions, including carcinoma of the stomach, to which achlorhydria gastritis predisposes. The development of the type of atrophic chronic gastritis which may undergo malignant degeneration is a very slow process, so that if an overhaul given at the age of 40 includes a test-meal, which gives a normal or high curve of acidity and shows no excess of mucus, the test-meal need not be repeated for at least five years. After that it would probably be wise to repeat it every five years up to the age of 65.

(b) *Prognosis.*—In every case of achlorhydria a second test-meal should be given immediately after thorough lavage of the stomach. We have now done this for six years, and have found that in about 50 per cent. of cases free hydrochloric acid appears in the second test-meal. In these cases the prognosis is comparatively good, as the condition is still largely catarrhal; when a normal or high curve of acidity is obtained it can be concluded that little or no atrophic changes have so far taken place in the gastric mucous membrane. On the other hand, when no trace of acid is present in the second test-meal, the patient has either constitutional achylia gastrica, which may or may not be associated with secondary gastritis, or he has a comparatively advanced stage of primary atrophic gastritis. Though the inflammation may be overcome by treatment, nothing can prevent the possibility of the abnormal mucous membrane subsequently undergoing malignant degeneration.

(c) *Treatment.*—A diet should be given which contains no mechanically irritating constituents, such as the pips and skins of fruit, coarse vegetables, salads, and tough meat, and no chemical irritants such as alcohol and a large proportion of drugs in common use, except in an extremely dilute form. The food should be very thoroughly masticated, and proper dentures supplied when required. Pyorrhœa alveolaris and infected tonsils and nasal sinuses should be very thoroughly treated, and the dentist should be visited at least every six months.

The stomach should be washed out each morning before breakfast with dilute hydrogen peroxide (one drachm to the pint), the lavage being continued until no further mucus comes away; the final washing should be with plain water. The nascent oxygen set free when the hydrogen peroxide comes into contact with the mucus dislodges it much more efficiently than any other fluid, and at the same time it acts as an antiseptic. The treatment, which the patient soon learns to give himself, is continued daily with gradually increasing strength of hydrogen peroxide until no more mucus is present. It should then be continued on alternate days, then twice a week, and finally once a week for some months. Another course of treatment should be given if there should be a recurrence of symptoms, and in any case a test-meal should be given once a year, so that if the gastritis returns it can be treated without delay.

At one time I advised the administration of large doses (ʒ1 to 2) of dilute hydrochloric acid with pepsin, suitably diluted, before breakfast, and as a beverage with lunch and dinner, in all cases of achlorhydria. It is clear, however, that it is far better to restore the normal secretion of acid by treating the gastritis whenever this is possible. I therefore only give acid in those cases in which there is still no acid or insufficient acid after the second test-meal; a third test-meal should be given at the end of the first course of lavage, as the acid may have then returned even if none was present in the second test-meal, or extreme hypochlorhydria may have given place to a normal curve of acidity. Only when hypochlorhydria or achylia is found at the third test should hydrochloric acid be given continuously. It is not only useful for digesting meat and softening and diluting the food, but its antiseptic action helps to overcome the gastric infection and to prevent reinfection from the mouth or bowel.

Polyposis of the stomach.—This condition gives rise to symptoms suggestive of malignant disease. But the history is likely to be a long one without any recent aggravation, and there is generally little or no pain. In the only uncomplicated case of the kind I have seen weakness from the long-continued severe anæmia caused by the constant oozing of blood had been present on and off for nine years, together with nausea and occasionally attacks of diarrhœa and sickness.

The condition is sometimes indistinguishable from cancer with the X rays, but it may give such a characteristic picture that occasionally a correct preoperative diagnosis has been made. Achlorhydria is generally present, and one or more fractions contain blood, which is therefore always present in the stools.

The only safe treatment is partial or complete gastrectomy, as malignant degeneration may occur at any time, and it may be impossible to tell clinically or on abdominal exploration whether this has already begun. In my case, which I recorded with Adrian Stokes,[11] almost complete gastrectomy was successfully performed by Mr. Lancelot Bromley.

2. *Chronic Gastric Ulcer.*

(a) *Diagnosis.*—Though often latent in its early stages, a chronic gastric ulcer sooner or later almost always gives rise to symptoms, which, though less characteristic than those of duodenal ulcer, are sufficiently well marked and persistent to call for further investigation. It is possible to recognise the presence of every chronic ulcer of the stomach with the X rays, but it is always desirable to obtain further information by means of a test-meal and by examining the stools for occult blood before carrying out treatment.

(b) *Prognosis* and (c) *treatment.*—A gastric ulcer can be regarded as successfully treated when it has been replaced by a sound scar. This not only results in the disappearance of symptoms, but there is very little danger of malignant degeneration of a scar. In Stewart's[9] series of 259 specially studied operation specimens there was only one example of cicatrix-cancer compared with 11 of ulcer-cancer. I am convinced that all chronic ulcers of the stomach, however large and however deeply they may involve the pancreas, are capable of healing under prolonged medical treatment so long as they have given rise to no mechanical obstruction. When, however, an hour-glass stomach has developed or a prepyloric ulcer has caused pyloric obstruction, an operation should be performed. In my experience a gastro-gastrostomy, which is a far easier operation than excision, is all that is required for an hour-glass stomach; the ulcer always heals, and, moreover, it is a remarkable fact that ulcers causing hour-glass constriction rarely, if ever, become malignant. Theoretically the rare prepyloric ulcers, like the much more common duodenal ulcers which cause obstruction, would seem to call for gastro-jejunostomy, which always results in rapid healing; but as no less than 3 out of Stewart's 9 and 11 out of Orator's 84 prepyloric ulcers removed at operation showed clear signs of malignant degeneration, partial gastrectomy should be performed in all cases, as it may be quite impossible to recognise early malignant changes by simple inspection, and the X rays give far less definite information than in the case of lesser curvature ulcers. I can, however, see no reason for advising surgical treatment of a gastric ulcer producing no obstruction. Those cases in which medical treatment requires to be prolonged to three or four months are just those in which radical surgical treatment is difficult or impossible. Though gastro-jejunostomy may ameliorate the symptoms, the ulcer often does not heal, and so the possibility of malignant degeneration is not prevented. Jejunostomy does nothing which medical treatment cannot do more efficiently, and I have had two cases in which an irremovable ulcer near the cardia only healed on allowing the jejunostomy to close and instituting the usual medical treatment. As local excision was followed by recurrences within a year in 43 per cent. of 78 cases in the combined statistics of Dobson,[24] Sherren,[25] and Collinson,[26] recurrence would probably occur sooner or later in quite 75 per cent. of cases. Quite apart from the fact that partial gastrectomy, the only really radical operation for gastric ulcer, is only possible in those cases in which medical treatment is most likely to be effective, the mortality in the hands of the average hospital surgeon is probably at least twice as great as the risk of malignant degeneration, which was present in 4·6 per cent. of Stewart's 172 cases and 2 per cent. of Orator's 300 cases of lesser curvature ulcers. It is clearly wiser to undergo adequate medical treatment, if necessary prolonged for as much as three months, and survive, than run the risk, small as it may be, of death from operation. Whether the treatment is medical or surgical, it is, of course, essential to remove all foci of infection and to give the patient written instructions as to the régime he must follow in order to prevent a recurrence.

3. *Adenoma of the Stomach.*

Simple adenomata of the stomach, whether single or multiple, rarely give rise to any symptoms. If recognised, they should be excised on account of the great danger of malignant degeneration.

If the conclusions I have drawn in this lecture prove to be correct, the last word will be with the general practitioner and the physician, whose duty it will be to teach prophylaxis and to recognise the first signs of the precancerous conditions of the stomach. We may then confidently look forward to a time when the disorders, so ably described by Sherren and by Walton at this hospital as the "surgical dyspepsias," will cease to be surgical, for while some will be prevented, the remainder will be diagnosed at a stage in which they are still curable by non-operative treatment.

ON THE

SYMPTOMATOLOGY OF INTESTINAL AMŒBIASIS.

BASED ON A STUDY OF 150 CASES.

BY PHILIP MANSON-BAHR, D.S.O., M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON;
AND
C. B. V. TAIT, M.R.C.S. ENG.,
LATE HOUSE PHYSICIAN TO THE HOSPITAL.

THE more extensive his experience of intestinal amœbiasis, the more the practitioner is bound to be impressed by the great variety of the symptoms which infection with *Entamœba histolytica* may provoke. No very great difficulty is to be apprehended in diagnosing the classical type of intestinal amœbiasis in patients complaining of a definite abdominal syndrome and the passage of blood and mucus in the stools; but it is by the less dramatic forms, or by those which present symptoms which might well bear a different interpretation, that one is liable to be led astray. During recent years we have been greatly struck by the diverse character of the amœbic syndrome, and did we not make it an invariable practice to examine the fæces microscopically in every case from the tropics presenting abdominal symptoms, we feel morally certain that, in quite a considerable proportion of cases, the correct diagnosis would have been missed. There are certain bizarre types in which constipation and flatulence constitute the outstanding features; others in which there is chronic diarrhœa; others again in which the symptoms appear to point to the gall-bladder, stomach, duodenum, and appendix as the seat of the trouble.

A study of the recent literature of intestinal amœbiasis reveals the fact that other observers, especially in America, have drawn attention to similar phenomena. James and Deeks,[1] in 1924, and more recently James[2] alone, have found that latent *histolytica* infections far exceed in number those associated with purely dysenteric symptoms at the time of examination. The latter is convinced that in Central and Northern South America *histolytica infections* cause a very large proportion of obscure gastro-intestinal troubles. Craig[3] also believes that the classical picture of amœbic dysentery is noted only in a minority of cases infected with *E. histolytica*. Musser,[4] in 1925, published an excellent account of the subject viewed from the clinical aspect. He remarks that out of 72 cases definitely diagnosed as amœbic dysentery, no less than 40 complained of chronic diarrhœa; 1 was admitted on account of asthma, 2 on account of rectal pain, and 13 on account of varying degrees of pain in the abdomen. Montier,[5] in 1922, described the more obscure forms of amœbic colitis. Some patients, he has noted, may even be constipated, whilst the misleading forms are those cases of intestinal amœbiasis in which the main symptoms are located to the right hypochondrium or to the hepatic flexure of the colon where the diagnosis has to be made from hepatic and biliary disease.

It is with the idea of emphasising the importance of these aberrant forms that we have analysed the symptoms of 150 consecutive cases of amœbic dysentery as they have occurred in practice during the last nine years. With a few exceptions, all these cases have acquired their infections in the tropics and have returned to England for treatment. In every case cited in this paper the diagnosis has been rendered absolute by the discovery of the active forms or cysts of *E. histolytica* in the fæces; these diagnoses have been reinforced in the majority of instances by sigmoidoscopic examination. The main features of this inquiry may be summarised in the accompanying table.

Analysis of 150 Cases of Amœbic Dysentery, Symptomatology, &c.

Distribution of Pain.

(Male cases, 133. Female, 17.)

Abdominal pain or discomfort—	
Present in	126
Absent in	24

	Cases.
Generalised abdominal pain	70
Epigastric discomfort ..	10
Liver area..	9
Gall-bladder area (right costal margin)	2
Right shoulder (referred pain)	2
Gastric localised	3
Duodenal localised	1
Transverse colon	1
Cæcal and appendicular..	7
Sigmoidal and descending colon	10
Lumbar localised	2

Maxima and Minima.

	Years.
Age at onset—	
Maximum	64
Minimum	$10^{10}/_{12}$
Maximum duration.. ..	30
Maximum period without active symptoms ..	6

Bowel Symptoms.

	Cases.
Diarrhœa	114
Alternating diarrhœa and constipation	8
Constipation	11
Normal regularity of motions	17
Flatulence	37

Bowel Symptoms (cont.).

	Cases.
Tenesmus	34
Blood and mucus in stools	71
Mucus only in stools ..	18

General Symptoms.

	Cases.
Pyrexia	18
Hepatitis	9
Emaciation	43

Previous Diagnoses.

	Cases.
Neoplasm of pancreas—laparotomy	1
Cholecystitis and cholelithiasis	2
Appendicitis and appendicectomy	4
Duodenal ulcer	1
Tuberculosis	1
Bacillary dysentery ..	1
Septicæmia (pyrexial case)	1

Intercurrent Diseases.

	Cases.
Kala-azar	1
Hepatic abscess	5
Tuberculous mesenteric glands	1
Pulmonary tuberculosis..	1
Malaria and ankylostomiasis	1
Malaria and ascariasis ..	1
Cystitis	1
Pregnancy	1
Pneumonia	1
Malaria	2
Sprue..	2
Gonococcal epididymitis..	1

Sex and Age Incidence.

A number of points present themselves for discussion. The overwhelming preponderance of the male is easily explicable by the greater exposure of men to liability of infection, and the relative smaller number of women proceeding to the tropics.

As regards age incidence, intestinal amœbiasis, in the European, at any rate, is a disease of adult life. Personally we have never seen amœbic dysentery in young children. What is generally taught, and we maintain to be true, is that dysentery in children is almost invariably bacillary in origin, and that amœbic dysentery is rarely, if ever, contracted before the tenth year. As will be seen by the table, the minimum age at onset in this extensive series is 10 years 10 months.

In this case the patient was the son of a missionary, who was working in the Shantung Peninsula, China. He had been born in China, and returned to England in March, 1927. Whilst in China he had one attack resembling dysentery. The real attack of classical amœbic dysentery commenced soon after his return to England in March and December, 1927. He was seen in the third relapse in February, 1928. The boy was passing typical blood and mucus stools, of which he had three to four daily. His general health was not much undermined, and there had been no appreciable loss of weight. The fæces contained numerous active *E. histolytica*. An apparently permanent cure took place after anti-amœbic treatment.

The oldest case in this series was a retired official, aged 64, who had returned from Burmah in 1922. Two years after his retirement he commenced to suffer from intermittent attacks of diarrhœa without obvious dysenteric signs. The fæces were found to contain *E. histolytica* cysts.

Latency.

Duration of Infection.—That intestinal amœbiasis may be one of the most persistent of all protozoal infections is well known. In four cases in this series the infection with production of symptoms had persisted for over 20; in one instance it had lasted 30 years.

This patient, a retired planter from Ceylon, had first contracted dysentery in 1897, and had suffered intermittently from colitis ever since. When seen in May, 1927, he was passing diarrhœic fæces containing *E. histolytica* cysts, which were successfully cultivated on Boeck and Drbohlav's medium.

A second case was seen in a printer in 1928. In this case the infection had lasted 20 years, and had been contracted on military service in India. This man had been residing in England for 28 years. In a third, seen in 1929, the infection had been contracted during the South African war in 1901, and he had continued to suffer from dysenteric attacks almost periodically since. Some ten years ago appendicostomy had been performed, and the colon periodically washed out. Although this afforded relief, it had not by any means cured the condition as *E. histolytica* cysts were found in the fæces.

That the symptoms of dysentery may vanish temporarily, even for long periods, with apparent restoration to health, has long been recognised; a year or more may elapse after the cessation of treatment before signs of the disease make themselves evident. Symptoms of dysentery may also become apparent long after the return from the source of infection. There may be a latent period of six years, as in the following case:—

A hairdresser was seen in 1929. He gave a history of frequent attacks in India, where he was born and had spent his youth. Returning to this country in 1922 he had good health for six years, and it was not till the end of 1928 that blood and mucus again appeared in the fæces. On his admission to St. Mark's Hospital the amœbæ were easily recognised in scrapings made from intestinal ulceration by sigmoidoscopy, and the case was kindly referred to us at the Hospital for Tropical Diseases, where the diagnosis was confirmed.

A second case was seen in 1923 in a soldier who served in France in 1916, where he evidently contracted the infection. Fresh symptoms of amœbic dysentery first became apparent in 1922, when the nature of the disease was proved at sigmoidoscopy and active *E. histolytica* were found in scrapings made from the bowel.

Latent periods of two or three years are comparatively common. It is the honest appreciation of this peculiarity of intestinal amœbiasis which renders it so very difficult to assess the permanent value of any particular form of treatment. It seems that the clinician has to wait six years or more to finally ascertain whether the cure has in effect been successful.

The recurrence or relapse may be acute; the onset sudden with violent diarrhœa and loss of weight. In one instance the quiescent period appeared to be as long as nine years.

This was in a sea captain who was seen in June, 1928, in an acute attack of amœbic dysentery. Cysts of *E. histolytica* were found in the fæces, and on sigmoidoscopy the typical ulceration was seen. The history clearly indicated that dysentery commenced in 1910, and that the last definite recurrence had been in 1919, when the organisms were discovered in the fæces in Liverpool.

Symptoms.

Localisation of Pain.—The absence of any distressing abdominal pain and general innocuity of the symptoms and their compatability with fair health are an outstanding feature. No very evident signs were elicited in 24 cases. In other words, amœbic dysenteric infection may be compatible with average good health.

In intestinal amœbiasis subjective pain is, as a rule, localised to certain definite areas of the large bowel; it may be, as it usually is, confined to the sigmoid and descending colon (ten cases), or to the opposite side of the abdomen, to the cæcum and appendicular area. In seven cases of this series the pain experienced by the patient and elicited by pressure was confined to the cæcum, the outlines of which can occasionally be ascertained on deep palpation. This localisation of pain is often mistaken for appendicitis, and not unnaturally the appendix may be at first suspected and removed. While not denying the frequency of true appendicitis in tropical countries, the coexistence of amœbic dysentery with pain localised to the cæcum is frequently mistaken for it. So far we are not convinced that we have encountered a case of appendicitis primarily due to amœbic infection.

Pain may be localised to the centre of the transverse colon, and an area of deep tenderness may be elicited in the epigastric triangle. The localisation of amœbic ulceration to this part is rare without the implication of other tracts of the large bowel; but when it does occur it may be most misleading. This accounted for six cases in our series: two in which the pain was registered at the outer border of the right rectus muscle and had been mistaken for gall-bladder tenderness, three in which the pain appeared in the stomach itself, and one in whom it was definitely located to the transverse colon. Then there is a small group in which the abdominal pain is referred to the lumbar region, in which case suspicion of renal trouble was quite justifiably entertained.

Emaciation is the rule in acute amœbic dysentery. In 43 cases of this series the usual loss of weight is from 14–28 lb. in a year, the greatest loss recorded being one of 42 lb. in three months. On the other hand, chronic intestinal amœbiasis so little interferes with nutrition that actual increase of body-weight, even to the extent of obesity, may be recorded. We have records of three cases in which a considerable increase of body-weight occurred. In one the duration of the disease with acute symptoms was of ten years, with an increase of 28 lb.; another in a soldier, of four years' duration, with a similar increase; a third in a lady, of three years' duration, who had in the meantime become extremely stout, but no actual figures of weights were obtainable.

Bowel Symptoms.—Obvious and chronic diarrhœa, without the appearance of blood and mucus in the stools, was the outstanding feature in no less than 114 cases. This significant fact gives support to Dobell's contention that the term "amœbic diarrhœa" must, in the majority of instances, supplant the term "amœbic dysentery." We believe that chronic "amœbic diarrhœa" is a much more common complaint than "amœbic dysentery," and that in a great many instances these amœbic diarrhœas are painless and are not accompanied by any very evident involvement of the bowel wall. Usually periods of diarrhœa alternate with those of constipation (eight cases). On the other hand, the anomalous fact asserts itself that constipation may constitute the outstanding feature of the case. We have records of 11 such. Illustrative cases are as follows:—

A young man of 28 years contracted an intermittent form of diarrhœa whilst on military service in India from 1919–22. For five years after his return to England from India he had suffered from chronic constipation, flatulence, mental and physical exhaustion, with loss of weight of 14 lb. Tuberculosis of the abdomen had been suspected. The bowels were never open, save by strong aperients. The cysts of *E. histolytica* were found, and were cultured from the stools. Loss of flatulence and increased regularity of the bowels followed a rigorous course of anti-amœbic treatment.

Another good example occurred in a locomotive driver in the Nigerian service, who complained of chronic pain in the left side of the abdomen, and the most obstinate constipation as a sequel of an acute attack of amœbic dysentery. The fæces contained *E. histolytica* cysts. The regularity of the bowels was greatly improved by anti-amœbic treatment.

Flatulence may be a most distressing symptom. Usually it is confined to the ascending colon and the cæcum. It may be obvious to the examining eye. Flatulent distension of the cæcum with retained gas, and which occasions a splash on palpation (well termed the "amœbic splash"), is so frequent as to be almost diagnostic. Flatulence is tabulated as a feature in 37 cases in this series. It may be so obvious and persistent that chronic pancreatitis or chronic intestinal obstruction may be suspected. A typical example is as follows:—

A lady was seen in 1928 whose chief complaint was loss of weight, chronic constipation, and flatulence. She had lost her complexion, the skin was harsh and dry. She presented, in fact, the clinical picture of intestinal toxæmia. The flatulence was confined for the most part to the right iliac fossa in the vicinity of the cæcum. Both sigmoid and cæcum could be easily palpated. The fæces contained *E. histolytica* cysts. Both constipation and flatulence were entirely cured by anti-amœbic treatment.

Dyspepsia.—Acute dyspeptic symptoms are often associated with flatulence. Rarely cases are encountered in which the tenderness and acuteness of pain are referred to the pit of the stomach. These are usually long-standing infections with considerable infiltration of the bowel wall.

One typical example was seen in January, 1927. The pain was referred to the right hypochondrium, especially when lying on that side. The cæcum was infiltrated and thickened, and easily palpable. The fæces contained *E. histolytica* cysts. *The dyspeptic symptoms disappeared after efficient anti-amœbic treatment.*

Cases Simulating Duodenal Ulcer.—The possibility of intestinal amœbiasis being mistaken for duodenal ulcer is one that rarely arises, but the one particular case in this series was so remarkable that a few details must be given.

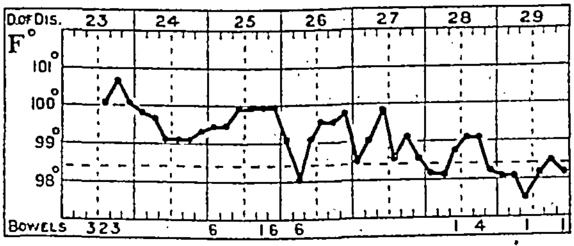
A quartermaster of an Indian liner, aged 45 years, was seen in March, 1927. This man had, three years previously, suffered from liver abscess, for which an operation was performed. After this he appears to have suffered from chronic supra-umbilical pain, flatulence, and dyspepsia. On March 17th, 1927, he was suddenly taken ill with acute abdominal pain, vomited bright blood, and passed a number of black, tarry, melænic stools. Two further bleedings took place within the next ten days, till the condition of the patient became desperate. *The anæmia was so profound* that blood transfusion had to be resorted to.

On microscopic examination of the melænic fæces one active *E. histolytica* was seen. No improvement followed the usual alkaline and dietetic treatment for duodenal ulcer, but on the other hand emetine injections of gr. 1 for six days effected a most remarkable improvement. This was reinforced later on by a complete course of emetine bismuth iodide and yatren intrarectal injections. A complete cure appeared to have been produced. The improvement to the blood picture, general appearance, and weight of the patient were alike remarkable.

Acute Amœbic Dysentery.—One of us (P. H. M-B.) has recorded[6] a case of acute onset and course with fatal results within 14 days of the onset. Such instances are extremely rare. Amœbic dysentery may, however, produce the most profound cachexia, almost resembling that of malignant disease.

A man of 29 years of age was treated in May, 1928, on his return from Nigeria. The nature of the illness had already been recognised, and he had been treated with a total of grs. 60 of emetine continuously, but the present was the most severe attack he had experienced. He had lost 28 lb. in weight within a month. The diarrhœa averaged 12 blood and mucus stools a day. The patient was obviously cachectic, the sigmoid and cæcum were definitely thickened, while on sigmoidoscopy most extensive and deep ulceration was present. *E. histolytica* were demonstrated in large numbers in scrapings from these ulcers. The response to the combined treatment with emetine-bismuth iodide and yatren was remarkable. He regained *18 lb. within the same number* of days. This was one of the worst cases from the clinical aspect we have ever seen.

FIG. 1.



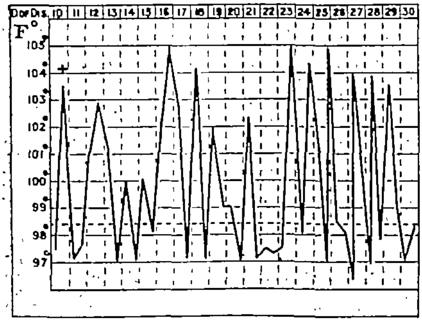
Four-hourly temperature chart in a case of acute amœbic dysentery, associated with toxic absorption showing the character of the pyrexia.

Pyrexia.—The course of a straightforward case of intestinal amœbiasis is usually apyrexial. The absence of anything like a high temperature is usually regarded as a valid point of differentiation between intestinal amœbiasis and bacillary dysentery. It is necessary to point out that this is by no means an invariable rule. In the present series there were no less than 13 cases associated with pyrexia which could not be accounted for by any other associated infection, or by coincident amœbic hepatitis.

The character of the pyrexia can be gathered from the accompanying temperature chart (Fig. 1); it is probably due to the absorption of septic matter from the bowel wall.

This patient was a ship's engineer, who was admitted to hospital in 1929 with acute amœbic dysentery, passing some 10–20 blood and mucus stools daily. The patient looked ill, with pinched facies and furred tongue. The abdomen was tender, and the cæcum and sigmoid were indurated and palpable. There was no evident enlargement of the liver. The pyrexia rapidly subsided on emetine and emetine-bismuth iodide treatment.

FIG. 2.



Temperature chart in a case of acute amœbic hepatitis with multiple rigors. The cross shows the time at which cysts and pre-cystic forms of *E. histolytica* were found in the fæces.

Pyrexia Resembling Malaria.—The fever may be so acute in onset as to resemble a malarial attack for which it is often mistaken. Of these no less than five cases have been seen where the previous diagnosis founded on the symptoms of the patient indeed had been malaria. We are convinced that these attacks are due to recurrent embolism of the liver by amœbæ derived from the bowel.

A remarkable case of this nature was admitted to hospital in November, 1927. The patient had served for years in India, where he had suffered from dysentery, and had returned in 1923 to England. A latent period of five years elapsed during which he had no symptoms. Then in August, 1927, a series of rigors commenced, resembling closely in the onset and nature that of benign tertian malaria. They were accompanied by the most profuse sweats. Sometimes two rigors occurred within 24 hours. The temperature frequently rose to 105° and 106° F. (Fig. 2). This lasted throughout three months, *till* the state of the patient became very alarming. The diagnosis was established by the discovery of active *E. histolytica* and its cysts in the fæces, together with the existence of a leucocytosis of 30,000. The amœbæ were subsequently cultured from the fæces. Eventually in December, 1927, on vigorous anti-amœbic treatment the patient made a good recovery. Although the liver was enlarged to percussion, and as ascertained by radiographic examination, there was never any acute pain referred to the organ as is usually the case in amœbic hepatitis.

These malaria-like attacks may persist over many years, and then their nature is usually quite unexpected until the stools are microscopically examined.

A fish salesman was seen in July, 1929, with a history extending back over eight years. Originally infected with amœbic dysentery in Syria, in 1918, he had on one occasion only passed blood and mucus in the stools. Ever since that time he had been subject to attacks of otherwise inexplicable diarrhœa. In June, 1929, he commenced to suffer from bouts of fever, with rigors and faintness and tenderness over the liver at the costal margin. The sigmoid flexure and descending colon were distinctly palpable. *E. histolytica* cysts were present in the fæces. There was a leucocytosis of 16,000. Immediate improvement and cessation of febrile attacks took place on anti-amœbic treatment.

Continuous Pyrexia.—Another striking case occurred in a young woman who had returned from India in 1927 and was seen a year later.

She had been taken ill at Marseilles in December, 1928, with recurrent attacks of four bouts resembling closely those of malaria, associated with abdominal dysenteric symptoms. The temperature frequently rose to 104° or to over 105° F. On admission to hospital in January, 1929, she was passing dysenteric motions containing active *E. histolytica*. She had two subacute rigors associated with a leucocytosis of 14,000. *The pyrexia speedily resolved, and* the condition entirely cleared up on anti-amœbic treatment.

Ulceration of the Rectum Without Involvement of the Rest of the Large Bowel.—The amœbic ulceration of the rectum may be solitary, and the ulcer may be of a large size and give rise to considerable local pain. The ulcer from its site, from its general character, and from the nature of the incessant blood-stained discharge, may closely simulate that of malignant disease.

We have the record of one such case in a man of 37 years of age seen in May, 1928. The condition had persisted for two years. On sigmoidoscopy a large ragged ulcer, 3 cm. in diameter, situated in the rectum, 6 cm. from the anal margin, was discovered. In its indurated character and the ragged nature of the margins of the ulcer it did not resemble an amœbic ulcer; nevertheless, active forms of *E. histolytica* were discovered in the scrapings, and it entirely healed up on vigorous anti-amœbic treatment.

Intestinal Hæmorrhage.—It has long been recognised that severe intestinal hæmorrhage may take place from amœbic ulceration of the colon. It may be so sudden and so profuse that the amœbic nature of the case may not be recognised or even suspected. The difficulty of diagnosis is made doubly severe by the fact that the amœbæ themselves are washed away by the amount of blood and cannot easily be identified by microscopic examination.

A patient was seen in January, 1926. He had suffered intermittently from attacks of amœbic dysentery for over one year, and had been found to be a chronic carrier of *B. typhosus.* Subsequent to an attack of typhoid fever in 1916 on the occasion in question the attack had been ushered in by the most profuse dark melæna, consisting almost entirely of altered blood. He had lost about 3 st. in weight. With great difficulty a few typical *E. histolytica* were found in the melæna, and a permanent recovery followed after specific treatment.

Another good case was seen in September of the same year. This was a lady of 55 years of age, who had contracted the infection in Chile early in 1926. The illness had begun suddenly with a rigor and high temperature, with pain in the right shoulder and the right arm. The diagnosis eventually turned out to be that of a hepatic abscess which had ruptured into the right lung, producing the most profuse hæmoptysis. At the same time she passed large black tarry stools in which, on microscopic examination, an active *E. histolytica* was recognised. A complete course followed intensive anti-amœbic treatment.

Painful Spasmodic Contraction of Sigmoid Colon.—Spasmodic contractions of the bowel occur in amœbic dysentery, especially in long-standing cases, and in those in whom constipation is an outstanding feature. This spasmodic contraction may dominate every other symptom of intestinal amœbiasis.

A locomotive driver from Nigeria was seen in February, 1926. He complained of chronic constipation and pain over the descending colon and sigmoid, which, though usually of a dull aching character, was punctuated by acute exacerbation. The spasmodically contracted bowel could be easily palpated. Numerous *E. histolytica* cysts were present in the fæces. Vigorous anti-amœbic treatment entirely cleared up the condition.

Hæmorrhoids.—External piles are a very frequent concomitant of intestinal amœbiasis. Almost every case of long standing shows evidences of external piles. They are probably occasioned by the straining at stool which is a feature of this disease. As a rule, we do not advocate any active interference in these cases, as the piles recede and almost disappear when the underlying cause has been adequately dealt with.

Prolapse of Rectum.—As in the case of hæmorrhoids, so may prolapse of rectum be brought about by constant straining at stool.

We have seen one such case in a medical man, 37 years of age, who was seen in October, 1927. He gave a clear history of amœbic dysentery contracted in Mesopotamia in 1922. He had suffered from a great deal of diarrhœa with a little tenesmus, but the rectal prolapse had become gradually more pronounced. Large numbers of *E. histolytica* were present in the fæces, and a sigmoidoscopic examination revealed large numbers of characteristic ulcers. Without any additional aids, a complete and permanent retraction of the prolapsus recti took place on specific treatment. The patient has remained in good health, and has undertaken a large clinical practice ever since.

Sequelæ.—Stricture of the bowel, not any actual interference with the passage of fæces as the result of amœbic ulceration, has not been observed.

Dilatation of Colon (Megacolon).—Two instances of this condition, apparently the direct result of chronic amœbic infection of the large bowel, have come under notice. In both instances the gradual onset of the condition, coming on two to three years after the cause of amœbic infection, has been observed.

The most striking instance has been watched since 1920. This man contracted amœbic dysentery whilst serving in Mesopotamia in 1917. He had relapses of dysentery in 1919, for which he was treated with six courses of emetine-bismuth iodide, and another more severe one in September, 1920, for which he was treated by a more vigorous course of emetine-bismuth iodide in the Hospital for Tropical Diseases. He appears to have been entirely cured of his amœbic infection. From 1925–27 he was under continuous observation with enormous dilatation of the colon, especially of the transverse portion, resulting in the characteristic Hirschspring's disease. The abdomen itself was greatly distended, especially in the lower quadrant, where the constant meteorism occasioned the most acute discomfort. The condition revealed by barium enema was one of gross distension and sacculation of the whole colon.

The second case in a ship's officer was similar in its main features, and in both an intimate and direct association with chronic intestinal amœbiasis could be traced.

Sprue Secondary to Intestinal Amœbiasis.

We have records of two cases in which sprue-like symptoms supervened upon an amœbic infection.

The first was a young officer who contracted amœbic dysentery in Mesopotamia, whence he returned rather acutely ill with dysenteric symptoms and the passage of active *E. histolytica* in the fæces. During his course of treatment he developed a typical acute hepatitis. All dysenteric symptoms rapidly subsided on vigorous anti-amœbic treatment, but almost immediately developed sprue-like symptoms with stomatitis, aphthous ulceration of the mouth, and the passage of large frothy sprue-like stools. The sprue state lasted for just one month and yielded to dietetic treatment. This was in April and May, 1920, since when he has remained in good health.

In the second case it was difficult to determine whether the amœbic infection antedated the sprue or not, but when the patient, who was 55 years of age, and who hailed from Bangalore, came under treatment in August, 1927, he had lost 76 lb. (5 st. 6 lb.) of his body-weight. In addition to this emaciation there was shrinkage of liver, dullness, anæmia, and the stomatitis of sprue. The fæces were large, pasty, and frothy, but also contained blood and mucus and active *E. histolytica*. Treated with the combination of emetine-bismuth iodide and rectal injections of yatren he made a very good recovery, and on returning to India nine months later he weighed 14 st., or an increase of 104 lb. of body-weight.

We think that there is a very close connexion between amœbic dysentery and sprue. The frequency with which the latter supervenes upon the former is more than a mere coincidence. Here we have records of two cases in which these diseases merged imperceptibly into one another, and it almost suggests that in certain cases sprue supervenes as a sequel of intestinal amœbiasis.

Localities in which Intestinal Amœbiasis was Contracted.

The cases quoted in this series hailed from nearly all over the world. From India, China, Ceylon, East Indies, Aden, Palestine, Mesopotamia, Salonika, Gallipoli, Egypt and the Sudan, East, West, and South Africa, New South Wales, the Mediterranean area, Venezuela, West Indies, Cape Verd, and Canary Islands. There were three records of indigenous amœbic dysentery contracted in 1917–19 on active service in France, and one in Germany contracted whilst a prisoner of war in 1918. There is also the record of an indigenous infection contracted in London.

The patient, a stevedore, aged 60, was seen in the Albert Dock Hospital in 1928. He has never left this country, but for 40 years had worked upon ships from Calcutta and Bombay, and it is from this source probably that he contracted the infection, presumably from association with lascar sailors. He had been ill for over two years with very evident signs of dysentery, and had been treated for colitis and for possible lead poisoning (lead colitis). Unfortunately he broke his leg in October, 1928, and had to be admitted to hospital for treatment when the true nature of the "colitis" was recognised by the discovery of active *E. histolytica* in the blood and mucus stools. The response to anti-amœbic treatment was as instantaneous as it was remarkable.

Associated Diseases.

The intimate connexion between amœbic dysentery and hepatic abscess is universally recognised—in fact they are but different manifestations of the same infection—but curiously they are seldom observed at the same time in the same individual. This association was noted five times in 150 cases. In three the liver abscess had antedated the present attack of amœbic dysentery, and in two only, both severe cases, was a hepatic abscess present at the same time as the patient was suffering from intestinal amœbiasis. Amœbic dysentery coexisted with malaria also on two occasions and with kala-azar once. The peculiar relationship to sprue has already been noted.

Conclusion.

The connexion between intestinal amœbiasis and the signs and symptoms is difficult to determine precisely. It depends possibly on the nature and extent of the intestinal ulceration whether the pain and discomfort are referred to one portion of the bowel or the other. Why the same infection should produce active diarrhœa in one person, and chronic constipation and flatulency in a second, cannot at present be determined. It probably depends upon the amount of mucous membrane destroyed by the amœbic infection, or the resistance of the patient to this particular infection. The diversity in the nature and severity of the symptoms produced render intestinal amœbiasis one of the most protean of all protozoal infections.

EAST HULL MATERNITY HOSPITAL AND CLINIC.—A new Municipal Maternity Home and Infants' Hospital has recently been opened at Hull. The institution was founded by private munificence in 1912, but by 1915 the work had so greatly expanded that it was taken over by the corporation. The new premises, which already belonged to the city, have been adapted to provide 40 maternity beds, 16 cots for infants suffering from dietetic diseases, 8 beds for nursing beds, and 10 isolation beds. The hospital is a training school for midwives. In 1928 there was one death among the patients attended by a municipal midwife, and no death among the 645 women confined at the maternity home—one maternal death for 1085 confinements. On the other hand, there were 24 maternal deaths from the 5018 confinements which take place elsewhere in the city, or one death for every 209 confinements. On the same occasion there was opened the East Hull Clinic, which brings together five different departments scattered about the district. It is claimed that the Clinic "is, in many ways, unique," and it is pointed out that, under the special arrangements of the Hull Corporation, all children, whether under or over 5 years of age, can be treated. It is officially described as "an endeavour to provide a complete Public Medical Centre for East Hull."

THE INFECTIVITY OF ERYTHEMA NODOSUM.

By J. O. SYMES, M.D. Lond.,
CONSULTING PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

THE majority of cases of erythema nodosum, febrile and non-febrile, occur sporadically, and the closest investigation fails to reveal a possible source of infection. Then one meets two or more cases so closely associated one with the other that it is difficult to disregard the possibility of infection. Two illustrations of this have been brought to my notice recently by medical correspondents. For the following I am indebted to Dr. D. J. Thomas, of Melbourne :—

> A woman, aged 21, had a typical attack of erythema nodosum, subsiding quickly. A fortnight later her brother, aged 26, developed a sharp attack. Three weeks later her sister, aged 18, had tonsillitis and erythema nodosum. She had a congenital aortic defect, and her attack of erythema nodosum passed into acute bacterial endocarditis, which proved fatal about three months later.

The second instance was communicated to me by Dr. Victoria Tryon of Clifton :—

> Two female domestic servants, neither of whom had suffered from any previous illness, shared a common bedroom. One of them, aged 20, developed the rash of erythema nodosum on March 19th, 1929. There were no constitutional symptoms and the attack was over in nine days. Her fellow servant, aged 22, complained of stiffness in the joints on May 20th, and there was then some teno-synovitis of both patellar tendons. On June 3rd the rash of erythema nodosum appeared. The attack was a slight one; unaccompanied by constitutional symptoms, and she was well in eight days.

It would be easy to multiply such cases, both from one's own experience and from published reports. Even more common is the simultaneous occurrence of erythema nodosum in two or three members of the same family. Whilst the probability is that they have all been infected from a common source, one cannot conclusively refute the explanation that is so often advanced—namely, that the disease has been caused by some food poisoning or some defect of hygiene which has been common to all the sufferers.

> In 1920 I saw two sisters, one of whom developed erythema nodosum on March 20th and the other on March 23nd. One of these, a medical student, returned to her work on March 27th, long before the nodes had disappeared, and subsequently a nurse in the ward in which she was working developed erythema nodosum on April 8th, and a night nurse on May 2nd.

Small outbreaks of the disease in schools or institutions are not uncommon. Langford Symes saw 12 cases in a home of 100 young girls between May 14th and June 14th, 1907, and Arvid Wallgren[1] in 1927 reported an outbreak of 18 cases amongst a class of 34 girls. Wallgren believes erythema nodosum to be a form of tuberculosis, but the facts as stated are much more suggestive of an infective fever, for the girls were all between the age of 10 and 12 years; the cases occurred in batches as if one group had infected the next; and they occurred in the months of March, April, and May, when erythema nodosum is most prevalent. Larger outbreaks, attacking whole communities, are not infrequent. Wiborg saw 30 cases between November, 1921, and August, 1922, amongst an isolated community of 816 people at Bangsund. Dr. R. E. Roberts, medical officer of health of the Mynyddislyn Urban District Council, saw 50 cases during a period of five weeks in August and September, 1920.

Incubation Period.

It is very difficult to fix the incubation period of erythema nodosum. The notes of published cases are of little value, for as a rule the appearance of the rash is regarded as the beginning of the illness, regardless of the fact that there has frequently been a febrile period of from 7 to 14 days before the exanthem appeared. It seems, however, that the incubation period may be a very brief one. For instance, a case is reported in which a child who was suffering from erythema nodosum was admitted to a hospital ward, and nine days later two children in the ward developed the disease. There had been no previous cases of erythema nodosum in the institution. Ledoux relates the history of four girls who suffered from the disease. The first was attacked in December, the second followed nine days later, the third 12 days after the second, and the fourth 15 days after the third. My own experience would lead me to give an incubation period of about 14 days. A. A. Lendon estimates it at about 11 days. Whilst it is certain that the incubation may be brief, it is obvious that the interval between two associated cases is usually a long one, extending into weeks and sometimes months. For instance, in the case of the two domestic servants which I have already quoted the interval was nine weeks, and similarly, some years ago, I discharged a boy convalescent from erythema nodosum from the Bristol General Hospital on July 12th, and admitted his sister suffering from the same disease on August 31st. There are two possible explanations of this long interval between cases. The infectivity of erythema nodosum is very low and the ordinary healthy subject is able to withstand it. If, however, the resisting power be temporarily lowered from any cause, then the germ gets the upper hand, and the disease is developed. In this connexion it is noteworthy that erythema nodosum is very frequently preceded by a period of ill-health, or follows after some acute or chronic infection. Its close association with tuberculosis is possibly only an evidence of the debilitating result of this disease. Another possible explanation is that the infective organism survives for a long period, and the convalescent becomes a "carrier." In this way the infection would be comparable to that of diphtheria. In support of this view is the fact that relapses are not uncommon, and sometimes patients reinfect themselves over and over again. Lendon reported the case of a woman who, after a month of prodromal illness, developed the rash of erythema nodosum on Jan. 5th, 1899. Fresh crops of nodes continued to appear until the following August. The patient went to South Africa, and subsequently, in January, 1900, wrote saying she thought that she had seen the end of the illness, as the last traces had disappeared just two weeks before the date of writing.

Characteristics of the Infection.

A striking instance of how infection may persist in erythema nodosum is provided by the case of Mrs. A., whose history I detailed in my recently published monograph on this disease. This lady had her first attack at 18 years of age, and subsequent attacks when 21, 24, 27, 30, 32, and 37. By the courtesy of her medical attendant, Dr. Winifred Nott, I was able to see Mrs. A. in two subsequent attacks (eighth and ninth), one in April and the other in July, 1929. She was then 42 years of age. Although the acute attacks were several years apart, Mrs. A. stated that she was seldom free from nodules for more than a few weeks at a time. Any depressing circumstance or failure in general good health brought back a few spots. Four of the acute attacks occurred during pregnancy. Some authors have described such recurrent attacks or relapses as *chronic erythema nodosum*.

Another interesting feature in the incidence of erythema nodosum is the predilection it shows for certain families. Over and over again one sees two or three members of a family getting attacks of erythema nodosum. The attacks are many years apart, and often occur in widely separated members of the same family, so that one can exclude the possibility of infection by fomites or of one member being a carrier. Woringer calls such instances

---

[1] See THE LANCET, 1927, ii., 1030.

familial erythema nodosum, and maintains that they share a similar familial constitution which renders them peculiarly liable to this infection. Of such the following is an example :—

Mrs. N. Erythema nodosum in 1886 ; eldest daughter died during attack of erythema nodosum and endocarditis, 1900 ; fourth daughter had erythema nodosum in India in 1925, and a mild attack in England, 1927 ; fifth daughter had an attack in 1920, and second and third attacks in Egypt 1921 and 1922 ; the sixth daughter had attacks in 1916, 1920, and 1922.

Females are more than three times as prone to develop the disease as are males. There is no other infectious disease which shows this peculiar sex incidence.

The nature of the infective agent in erythema nodosum is at present unknown. On the continent the view is widely held that this disease is a modified form of tuberculosis, but in this country and in America it is increasingly regarded as a streptococcal infection. Rosenow claimed to have isolated a diphtheroid organism which, in some stages, assumed a streptococcal form, and which reproduced the disease in animals, but his work has never been confirmed. Whatever the organism may be, its activity in all European countries is greatest in March and April, and this groups it with such diseases as pneumonia, streptococcus infection, tuberculosis, and encephalitis lethargica, for which the winter months, by the absence of sunlight, prepare the soil. Infection takes place through the tonsils, and it is probable that it is in these organs and in the nasopharynx that it lies dormant for weeks or months.

THE USE OF
BISMUTH IN THE TREATMENT OF CONGENITAL SYPHILIS.

BY T. M. LING, B.M. OXF.,

JOHN AND TEMPLE RESEARCH FELLOW IN DISEASES OF CHILDREN, ST. THOMAS'S HOSPITAL.

SINCE its introduction in the treatment of syphilis by Sazerac and Levaditi in 1921,[1] bismuth has been accepted as an antisyphilitic remedy of undoubted value. Laboratory experiments and clinical trial have testified to its efficacy, and many French writers regard it as therapeutically superior to mercury. It is only natural that a drug which has proved of such value in acquired syphilis should be employed in congenital syphilis, a variety of the disease that is admittedly very refractory to treatment.

Among the first to report his experience with bismuth in congenital syphilis was Müller,[2] who treated six cases in 1922, and secured a good symptomatic response without toxic effects. In the following year Cajal and Spierer[3] reported the treatment of eight cases with a bismuth tartrate preparation, and stated that its therapeutic action on active manifestations was more rapid than that of mercury and as rapid as that of the arsenical preparations. Untoward symptoms were not observed. A suspension of bismuth salts in oil was employed by Torok.[4] In his experience bismuth proved to be a more satisfactory drug than either mercury or arsenic, owing to its ease of administration and low toxicity in therapeutic doses. Several other continental writers have expressed similar approval, while dissenting opinions as to its value are offered by Pinard[5] and Frank,[6] the former asserting that bismuth is not well borne by children, and that it often causes anæmia, emaciation, and lassitude ; while Frank had one death, apparently consequent upon bismuth therapy. Wright[7] has reported very good results, and was able to render 47 per cent. of his Wassermann-fast cases serologically negative, although prolonged treatment with arsenic and mercury had been previously carried out without effect.

Mode of Administration.

In my investigations "bisoxyl," a suspension in water of bismuth oxychloride and chloretone, has been used throughout, the injections being given deeply into the subcutaneous tissue of the thigh at weekly intervals, the dose varying with the age of the child. As a rule the initial dose was 0·1 g., gradually increased to 0·2 g. if no signs of intolerance developed ; this corresponds to 0·01 and 0·02 g. of the bismuth salt itself. The injections are only accompanied by momentary pain, unlike those of intramuscular arsenic, after which some degree of local swelling and tenderness usually persists for two or three days. This fact was constantly commented on and approved of by the mothers, some of whom sanctioned treatment with bismuth, although further arsenical treatment had been refused. On this account it is very much easier to ensure regular attendance with bismuth therapy, a very important point where the duration of treatment may be a matter of years. The site of injection was always well massaged after the administration of the drug, and in no case has any localised fibrosis occurred.

Intolerance to Bismuth.

As a general rule the symptoms of bismuth poisoning are similar to those of mercurial poisoning, except that recovery from the toxic effects is considered to be more rapid in the former. Anwyl-Davies[8] regards loss of appetite, accompanied in some cases by vague feelings of indigestion and headache, as the earliest manifestations of bismuth intolerance. Loss of weight is another early sign ; in this series the patients were weighed regularly every fortnight. The weight remained absolutely stationary in four, while one of the children, who developed albuminuria, lost weight quite markedly so that the treatment was stopped. A blue line on the gums may be regarded as a most valuable sign, as it is a guide to the amount of bismuth that can be tolerated, and is thus a good index of the appropriate dosage. At first a grey line forms round the edge of the gums, and this gradually turns to a bluish colour. Even when the line becomes definitely blue, provided that there is no stomatitis, the administration of bismuth need not be stopped, but the dosage should be decreased. Colonel Harrison[9] has pointed out that the blue line along the gum margin is more frequent when the soluble bismuth preparations are used, and that in all cases treatment should be stopped as soon as stomatitis is observed.

Clinical experience of the effect of bismuth on the kidneys bears out the conclusions that Brown, Saleeby, and Schanberg[10] reached experimentally on rabbits—namely, that the toxicity of bismuth is relatively low. It is presumably on account of this discrepancy between the therapeutic and the toxic dose that patients who develop albuminuria do not continue to show it for any length of time after the treatment is ended. This is well shown in Cases 14 and 15. Within six weeks of the cessation of treatment the urine was free from albumin, and there was apparently no impairment of kidney function as judged by renal efficiency tests. It is of interest to note that both these patients had received antisyphilitic treatment for over three years before commencing the bismuth ; as they were the only cases to develop albuminuria it is possible that the previous prolonged treatment with arsenic and mercury had to some extent damaged the kidneys and rendered them more susceptible to the subsequent bismuth.

Indications for Bismuth Therapy.

The most refractory cases of congenital syphilis from the serological point of view are, as a rule, those that first come under observation in later childhood, and are included under the term "lues tarda." Many of these cases persist with positive Wassermann reactions long after the outstanding physical manifestations have healed, and despite prolonged antisyphilitic treatment. Glynn, Roberts, and Bigland, in their Medical Research Council Report,[11] suggest very strongly that strains of *Spirochæta pallida* resistant to mercury may be produced by the prolonged administration of this drug in submaximal doses. Analogous results from arsenical treatment have been recorded by Klauder,[12] who has shown that it is possible to produce arsenic-resistant strains of *S. pallida* in rabbits by giving them small subcurative doses of arsenobenzol and inoculating the strain through several animals. The cases here recorded come under a combination of these two categories, as before their bismuth treatment they had all received repeated courses of intramuscular arsenic combined with mercury by the mouth. The cases are shown in the accompanying table, the intensity of the Wassermann reaction being recorded by the number of "pluses" in each case:—

Case.	Age.*	W.R.*	No. of A. injections.	Time under M. and A. tr.	W.R. after A. tr.†	Age at commencement of bismuth therapy.	Total number of bismuth injections.	W.R. after bismuth.†
1	8 y.	2	19	6 m.	1	8	6	—
2	7 y.	4	24	18 m.	2	8	12	2
3	8 y.	4	24	12 m.	3	9	12	1

15	10 y.	3	26	3 y.	2	13	10	2

* On first attendance. M. and A. tr.=mercury and arsenical treatment. † Number of pluses. y.=years; m.=months; w.=weeks.

Comments.—Case 5. Attendance lapsed. 9. Irregular attendance. 14. Albuminuria at end of second course. 15. Albuminuria treatment stopped.

Conclusions.

Although it is impossible in any one centre to secure a large number of suitable cases, these results tend to show that it is possible to render serologically negative a certain proportion of apparently Wassermann-fast congenital syphilitics by means of bismuth, and that its use is not accompanied by any untoward symptoms, apart from the occasional occurrence of temporary albuminuria. It is suggested that these results are due to the fact that the *S. pallida* has become resistant to arsenic and mercury after prolonged treatment

HOSPITALS AND MOTOR ACCIDENTS.—The Manchester and Salford Medical Charities Fund suggests that hospitals which treat motor accident cases should be brought in as beneficiaries in any scheme of compulsory insurance of motorists against third-party risks, and the governing body of the fund has passed unanimously a resolution urging this course upon the Government.—Lieut.-Colonel W. L. Kirby, chairman of York County Hospital, advocates the addition to all driving licences of one shilling to cover the cost of hospital charges caused by road accidents.

Clinical and Laboratory Notes.

AN UNUSUAL VAGINAL INFECTION IN A YOUNG MARRIED WOMAN.

By E. WORDLEY, M.D. CAMB., M.R.C.P. LOND.,
PATHOLOGIST TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

IN an address reported in THE LANCET last week (p. 981) Colonel L. W. Harrison dealt with various pitfalls in the diagnosis of venereal disease, and stressed the importance of a very complete examination before giving a definite opinion on the nature of any suspected venereal infection. He quoted an illustrative case where, because a newly married woman developed a Bartholinian abscess shortly after marriage, a diagnosis of gonorrhœa was made—erroneously, as it turned out after further examination—and caused very great distress to the parties concerned. A case has recently come to my notice where a similar mistake might easily have been made and a marriage wrecked. It proved a useful lesson against jumping to conclusions.

A young woman, aged 20, made a runaway marriage with a man a good deal older than herself, and against the wishes of her parents. Eight days after marriage and during the honeymoon she noted a profuse vaginal discharge and much irritation around the vulva. Thinking her husband had given her some venereal infection she came home to her parents. She was at once seen by her doctor who found all the signs suggesting an acute gonorrhœa. The girl's parents told him that if she had a gonorrhœal infection it was decided to institute divorce proceedings.

Smears from urethra and cervix were taken and sent to me for examination. Numerous pus cells were present and numerous Gram-negative diplococci both extra and intracellular were found, exactly resembling the gonococcus. I am certain that if similar slides had been sent up from a venereal diseases department with a diagnosis of gonorrhœa a return of "gonococci present" would have been made unhesitatingly. However, since I knew the details of this particular case, I stated that organisms resembling the gonococcus were present, and refused to commit myself more definitely. I said that if any question arose of giving evidence in any divorce proceedings I should have to examine the patient myself and take cultures if I was wanted to give any exact evidence. Accordingly, I made a personal examination of the patient. She had a thick yellow purulent vaginal discharge, the inguinal glands were enlarged, she was acutely tender on examination, and in short, presented all the symptoms of acute gonorrhœa. Films taken again showed numerous pus cells and Gram-negative intracellular diplococci exactly resembling the gonococcus. However, cultures on blood-agar yielded no colonies resembling the gonococcus but a pure growth of fairly large whitish rather opaque colonies. On staining these they proved to be Gram-negative diplococci of the exact size and shape of the gonococcus. But on first culture they grew luxuriantly on plain agar both at 37° C. and at room temperature. Maltose and dextrose were acidified but not lactose. Apart from the sugar reactions, the fact that abundant growth was obtained on plain agar at room temperature must completely rule out the possibility of the organism being the gonococcus.

The husband next came to see me stating positively that he had never had gonorrhœa and had now no urethral discharge nor anything to suggest an infection of the genito-urinary tract. I made a careful examination of his urethra, prostate, and urine. No signs of a urethral discharge were present. No pus cells or organisms were found in the urethra, prostatic secretion, or urine. Cultures from all three were sterile. I gave as my opinion that his wife was certainly not suffering from gonorrhœa, which opinion naturally gave the greatest satisfaction to both of them. In passing it may be remarked that the girl's parents had been chiefly responsible in emphasising the seriousness of her infection and the enormity of her husband.

The infection cleared up rapidly with simple antiseptic douches.

It appears certain that there was no possibility of the wife contracting her infection from anyone else, since both assured me most positively that until she went home to her parents they were hardly out of each other's sight. It is certain that the husband had no genito-urinary infection of any sort, so one must assume that the wife was infected with this organism, somewhat resembling the *Micrococcus catarrhalis* or an aberrant staphylococcus, as a result of trauma incidental to the early days of the honeymoon. She told me that she had had a great deal of pain following the first coitus. Her mother, it may be added, was positive that the girl had no vaginal discharge of any sort before marriage, and the daughter said so herself. Yet here was a young woman who, shortly after marriage, presented all the symptoms of acute gonorrhœa. Slides showed pus cells and an organism identical morphologically in all respects with the gonococcus. A report of "gonococci present" would have been made without hesitation on these findings combined with the history and appearance of the patient. Unless divorce proceedings had been contemplated it is quite possible that I should not have advised any further examinations to be made. If so a very serious error in diagnosis would have been committed with disastrous results to the future happiness of a young married couple.

The bare possibility that the infection was not venereal was present in my mind when I first saw the patient, for many years ago, when I was working in Prof. L. S. Dudgeon's laboratory, he described to me a similar case which he had seen in his own practice. Such occurrences show, I think, the importance of a very complete and thorough examination of both husband and wife when there is the slightest element of doubt about a venereal infection.

NOTE ON AN

ANAEROBIC STREPTOTHRIX OCCURRING IN SPUTA IN PULMONARY DISEASES.

By E. T. Thompson,

BACTERIOLOGICAL ASSISTANT, PICKETT-THOMSON RESEARCH LABORATORY, ST. PAUL'S HOSPITAL, LONDON.

THROUGH the coöperation of Dr. Mackenzie Douglas and Dr. Graham Willmore I have been enabled to investigate an anaerobe occurring in the sputum of cases suffering from tuberculosis, chronic bronchitis, bronchiectasis, and asthma which somewhat resembles the organism described by myself in a record of some symbiotic phenomena, with a note by Dr. R. O'Brien, published in THE LANCET (1920, ii., 186).

In the course of that work *Bacillus tuberculosis* cultures were infected with *B. proteus vulgaris*, the common proteolytic organism of the intestines. Briefly stated, the result was that after seven days' incubation at 37° C. *B. proteus* died out, but a Gram-positive non-acid-fast organism resembling the acne bacillus was found, and this organism could only be cultivated under anaerobic conditions. Further, a similar organism was isolated, when, instead of *B. tuberculosis*, a streptothrix was employed. The interest of this latter observation is increased by the fact that when the aerobic streptothrix of actinomycosis was employed in the experiment, the resulting anaerobe closely resembled the *Cohnistreptothrix israeli*, the common cause of actinomycosis in man in Europe. The organism did not resemble any of those commonly found in accidental contaminations, and every attempt was made to prevent the entry of adventitious bacteria into the mixtures under experiment.

Since the publication of the above results approximately 2000 sputa from 1000 patients have been examined at the Ministry of Pensions Hospital, Orpington, and Queen's Hospital, Sidcup. Of this number 118 cases were actively tuberculous with positive sputa. From these cases 172 sputa were treated and examined, and the anaerobic streptothrix was demonstrated in every case. In the other sputa the anaerobe was shown to be present in 65 per cent.

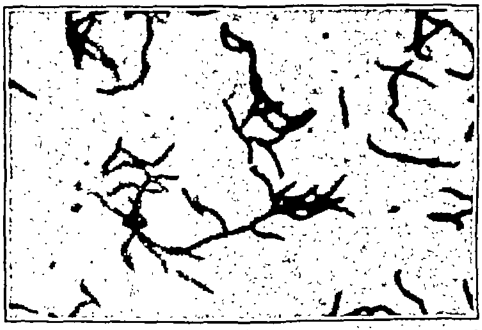
Method of Isolation.

The method employed in the isolation of this organism is as follows:—

About 0·5 c.cm. of sputum is introduced into a test-tube containing 10 per cent. glycerin in 1 per cent. peptone water 3 to 4 inches deep which has been previously autoclaved at 120° C. for 30 minutes. The mixture is then incubated at 37° C. It is not necessary to incubate under the usual anaerobic conditions, as the concomitant organisms produce a state of anaerobiosis which enables the anaerobe to grow when present.

Its appearance can generally be demonstrated in four to seven days, at the end of which time it usually reaches its maximum growth.[1] In Gram-stained specimens prepared from the sediment it will be easily recognised when present, as it is generally the only Gram-positive bacillus which develops, the other organisms present being mainly cocci. It resembles the tubercle and diphtheria bacilli, and sometimes shows true branching.

The removal of a portion of the sediment for the preparation of specimens or making cultures presents no difficulty if a finely drawn capillary tube with the upper end sealed is inserted into the sediment. When the capillary tube reaches the bottom of the sediment the sealed end is broken off, when some of the sediment will enter by capillary attraction. The tube is resealed before withdrawal to prevent any of the supernatant fluid entering. If on examination the growth of anaeromyces is considered sufficient for isolation, the remainder of the material is expressed into about 5 c.cm. of sterile water, saline, or broth. From this suspension shake cultures are made in 4 per cent. glucose agar 3 to 4 inches deep into a series of three tubes by inoculating from one tube to the other.



Microphotograph of organism from glucose agar culture. (× 1700.)

At the end of seven days small irregular opaque colonies will be seen in the depth of the medium resembling those of the acne bacillus. To examine the colonies and make subcultures a cut is made round the lower end of the test-tube with a glazier's diamond, and the cut is touched with a red-hot point of glass which will cause a clean crack round the tube, the bottom of which can now be easily removed. The column of glucose agar is blown into a sterile Petri dish. Isolated colonies can now be pricked with a straight platinum wire, for examination and making stab culture into 4 per cent. glucose agar. In three to five days growth will be noted, starting some distance below the surface of the medium. Specimens prepared from the pure cultures are Gram-positive but not acid-fast, and generally show many branching forms (see figure).

An Antiserum.

Marked deviation of complement with the sera of patients suffering from pulmonary complaints have been obtained by using a suspension of this anaerobe as an antigen. Although the organism is nonpathogenic to the lower animals a potent antiserum can be obtained by injecting it into rabbits, the serum having a high degree of agglutinability and complement fixation with its homologous antigen and *B. tuberculosis*. A few experiments have been carried out with this serum with a view to protecting guinea-pigs against infection by *B. tuberculosis*, and the results have been encouraging. Vaccines prepared from this organism have been used in cases of tuberculosis, chronic bronchitis, and bronchiectasis sometimes associated with asthma, with favourable results. Some cases have cleared up under this treatment which have proved resistant to all other methods.

---

In conclusion, I tender my thanks to Dr. Douglas and Dr. Willmore for the practical interest they have taken in this subject, and to Dr. David Thomson for the microphotograph.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

AT the meeting of this Section on Nov. 6th, with Sir HOLBURT WARING, the President, in the chair, a discussion was held on the

SURGERY OF THE SPINAL CORD.

Mr. HUGH CAIRNS said that usually the earliest symptom of a spinal tumour was pain in the back or along the distribution of the spinal nerves. It was described by patients as neuralgic, burning or tingling, or possibly it was only a sensation of tightness around the trunk or limbs. Often it was aggravated by exercise, coughing, bending, straining at stool, or even by lying down, so that some patients preferred to sleep seated in a chair. They would often admit that their extremities were cold, or that one foot was colder than the other, and the pain did not yield to drugs or measures which cured other pains. In the early stages careful examination would often disclose one or more signs of an early and incomplete Brown-Séquard syndrome. Stiffness of one leg, numbness of one foot, a creeping sensation about the ankles, or slight urgency of micturition during excitement or during a particularly bad attack of pain were some of the other symptoms that occurred before weakness set in. Often diagnosis was possible on careful clinical examination alone, but lumbar puncture provided confirmation. Usually there was blockage of the subarachnoid space, and Queckenstedt's test was valuable for its recognition. Positive results of the test could be seen even when there was no change of colour in the cerebro-spinal fluid. Mr. Cairns thought that the value of this test after operations had not hitherto been realised, and it was too often omitted during the preliminary investigation of a case. Sometimes the subarachnoid space was partly blocked and there was a delayed rise of pressure in the cerebro-spinal fluid, as shown by the manometer.

Surgeons, of course, were especially concerned with the position of spinal tumours lest they should overlook an easily removable tumour by exploring at the wrong level. In one of his cases the upper level of the sensory loss was at the eleventh thoracic dermatome, but further investigation after lumbar puncture showed a disturbance of sensation up to the level of the fifth, and the tumour was found at the sixth thoracic segment of the cord. This showed the importance of repeating the neurological examination after doing lumbar puncture. The upper level of the sensory loss should be tested not only by light touch, prick, heat and cold, but also by tuning-fork and by investigation of the patient's ability to appreciate numbers written on the skin. In compression the posterior columns were often affected more intensely, and at an earlier stage, than the lateral columns. Gordon Holmes had pointed out that careful observation of the movements of the intercostal and abdominal muscles would sometimes show the upper limit of the paralysis, while the tendon reflexes must be studied to determine the level of the lesion at the cervical and the lumbar enlargements. Mr. Cairns thought lipiodol should be used not to diagnose the presence of a tumour but rather to ascertain the exact level of a tumour which had been detected by clinical methods. It should be used, moreover, only when preparations for operation had been made. The lipiodol test was especially valuable in cases with two or more tumours of the cord. He was surprised that multiple tumours of the cord and its roots were not more often seen.

Little was known about disturbance of spinal conduction, went on Mr. Cairns, but compression of the cord by tumour should be distinguished from destruction of the cord by injury. In rare cases compression caused severe degeneration, precluding the possibility of restoring function, even after the tumour had been removed. As a rule, however, remarkably little degeneration of the cord had been found in patients who had shown severe paresis in life. The process of recovery varied remarkably in different cases. Sometimes it was evident in the paralysed limb within a few hours of removal of the tumour and soon became complete; in other cases it was delayed for a few weeks, but might nevertheless be equally complete. In other cases, again, it did not begin until a year or more after the tumour was removed and was then slowly progressive. On visiting Breslau last summer he found that Prof. Foerster had been operating on apparently hopeless cases of spinal compression, and had kept some of them in hospital for many years. One was a case of paraplegia in flexion, which has been treated for six years as disseminated sclerosis. Foerster removed a tumour from the first thoracic nerve root, and during the following 15 months the limb was straightened under anæsthetics and eventually the patient walked well. No case of spinal tumour was hopeless, and every effort should be made to get adequate institutional and orthopædic treatment during recovery.

Meningitis serosa circumscripta showed blockage of the subarachnoid space. If the adhesions could be broken up at operation the patient recovered in spite of the fact that in the few cases that had died post-mortem examination showed gliosis and scattered degeneration of the cord. The presence of adhesions and blockage of the subarachnoid space interfered with spinal conduction. Mr. Cairns found that satisfactory results from operation for spinal tumours could only be got if obstruction to the circulation of the spinal fluid was relieved. It was well to employ Queckenstedt's test after operation, especially in cases which were not recovering at the expected rate, for the subarachnoid space might still be blocked after removal of the tumour; there might be some adhesions at the site of the operation, or the tumour might have been incompletely removed, or another tumour might be present elsewhere in the spinal canal.

Mr. Cairns concluded by referring to the question of operative injury. The cord, he pointed out, was a very delicate structure, which should be respected even more than the brain; sometimes it came in for too much manipulation and its conductivity was thereby lowered. If due gentleness was observed in handling it at operation it should not show much depression afterwards.

The Queckenstedt Test and Lipiodol.

Mr. GEOFFREY JEFFERSON said that the principles of operation for cord tumours were in general those of the treatment of spinal compression as a whole. This was now on so firm a basis as to allow little room for discussion, and the methods employed were more or less stereotyped. There were, however, one or two points on which further information was still needed. The first was in regard to the Queckenstedt test, the importance of which had been emphasised by Mr. Cairns. It was true that by compressing the jugular veins one could judge, from the rapidity of the drops, whether blockage was present; but it was not a complete test and would not suffice for determining whether minor grades of blockage were present. At a meeting where he had demonstrated the results of the Queckenstedt test he had been criticised for speaking chiefly in terms of spinal compression, and it was said that he had not paid enough attention to the pain of spinal tumours. That was, in a way, a just criticism; it was true that the typical neurofibroma of the posterior root had for a time pain as its chief characteristic. But pain of a root character was not an outstanding symptom of anything like all spinal tumours. Any unexplained pain might be due to a posterior root tumour; but he did not know of anyone having been brave enough to operate for that pain alone when the legs showed no interference with conduction.

He had had a case of massive tumour of the cauda equina which filled the whole vertebral canal from the level of the first lumbar to the first sacral vertebra, but all the young man complained of was a little pain in his groin; he did not make a point of that pain, and it could only be elicited by pressure. He had bladder trouble and foot-drop, and he had been discharged from the Army as a case of hysteria.

Mr. Jefferson agreed with Mr. Cairns's remarks about lipiodol. Many cases were reported of supposed damage caused by lipiodol which did not bear close analysis, since it did not seem clear that the damage was not due to the disease process already present. It had been made evident that air caused a greater reaction in the cerebro-spinal fluid than did lipiodol. The profession seemed to be coming back to reliance on lipiodol for giving the exact level of the obstruction. In using the Queckenstedt test it was necessary to make certain that there was no fault in the apparatus.

He recalled the case of a young man who complained of tingling in his fingers and who was found to have some wasting of the interossei and disturbance of sensation at the sixth cervical segment. The Queckenstedt test was done and proved positive—i.e., there was no rise of pressure on jugular compression. At operation no cause was found for the block. Therefore, in three weeks the speaker did a second Queckenstedt test, using a larger needle, and made sure there was a free flow of fluid; on this occasion the test was negative.

Mr. Jefferson had heard it said that after operations in the mid-thoracic region there was likely to be severe vomiting, so severe sometimes as to cause death, and the suggestion had been made that the pain might be due to upset of the vegetative centres which controlled the stomach.

A woman aged 21 had come to him with very rapidly advancing symptoms of a complete transverse lesion of the cord. The condition was diagnosed as a transverse myelitis. He operated upon her and found a paravertebral sarcoma. That was entirely cured by radium, but without any improvement in her legs. At the end of three months she began to vomit; so severely did she vomit, and so distended was she, that he wondered whether she had a secondary deposit. Her blood-urea was five times the normal, and he did not doubt that was the cause of the vomiting.

This showed the importance of taking the blood-urea in all cases of spinal tumour before operation.

Discussion.

Mr. A. J. WALTON said that for prognosis in compression of the cord he had come to rely more and more on the time of development of the size of the compression. If the cord had not had time to adjust itself to its new position—i.e., if complete pressure symptoms developed in a few days—the chance of its recovering, no matter what was done, was very slight. This was a very different opinion from what was thought a few years ago, when the prognosis was based on the extent of the clinical damage and no regard was paid to the time element.

Dr. G. F. STEBBING said he had tried section of the anterolateral columns to relieve the pain of tabes, endarteritis obliterans, and malignant disease of the pelvis. In all these cases considerable relief was given, and in many it was complete. All the patients with tabes, however, had a recurrence of pain at some time after operation, though in one case the period of freedom was as long as four years. In some cases of pelvic malignant disease the pain was permanently cured. In only two cases were there evil results: one child had paralytic ileus six days after the operation, and in another there was temporary paresis of the legs, probably because of free handling of the cord.

Dr. GEORGE RIDDOCH thought the importance of root pain in extramedullary tumours could scarcely be exaggerated, though admittedly it was not always present. It might precede spinal compression by long periods. In tumour of the anterolateral column root signs might be absent, and location of the tumour was difficult. Progressive paraplegia in an adult justified suspicion of a spinal tumour. Meningitis serosa circumscripta differed in its clinical features, in most cases, from spinal tumour. The root pain of the former was diffuse and involved the supply of several roots as the condition progressed, on one or both sides of the cord. It had, however, the same slow malignant development. As a rule the position of the pain accurately indicated the site of the tumour. As to the mechanism of the production of symptoms, Sir Henry Head and he had laid stress on the vascular changes as being the main cause of the paraplegia itself, also as being the reason why the symptoms might clear up after operation. Dr. Riddoch doubted whether direct compression of the neural elements played an essential or important part in the disturbance of function in compression lesions, except in later stages. He agreed with Mr. Walton about the rapidity of symptoms of compression indicating the gravity of the prognosis.

Mr. J. PATERSON ROSS spoke of the case of a woman, aged 40, who was suffering from a spinal tumour, which was considered to be lying in an extradural position. In the opinion of Prof. G. E. Gask it was removed completely, but the patient did not improve, she slowly went downhill. He now thought it likely that the interdural projection of the tumour had been missed; the dura had not been opened.

The PRESIDENT remarked that little mention had been made of the use of radium for spinal cord tumours. He had had no experience of radium in these cases, but he had heard of a number in which radium had apparently stopped the growth.

Mr. CAIRNS, in the course of his reply, said that small doses of radon could safely be applied close to the cord, but large doses were contra-indicated, because they might destroy the cord as well as the tumour. Surgery of the spinal cord gave a good opportunity of observing the disturbance of the visceral and sympathetic fibres.

SECTION OF OPHTHALMOLOGY.

AT a meeting of this Section on Nov. 8th Mr. CYRIL WALKER, the President, took the chair, and after a number of clinical cases had been shown a paper on

RETINITIS IN DIABETICS

was read by Dr. P. J. CAMMIDGE. Although retinitis in the eyes of diabetics had been described some 70 years ago, there was still, he said, considerable doubt about its ætiology. The view at first adopted, and accepted by all the earlier observers, that the retinal changes were a direct result of the presence of an excess of sugar in the blood, had been abandoned by most modern authorities, mainly on the ground that the incidence of the complication and the severity of the primary disease did not show the relation which might be expected if this explanation were correct. The frequent presence of albumin, as well as sugar, in the urine of diabetics suffering from retinitis and retinal hæmorrhages had suggested an alternative hypothesis—namely, that the eye changes were dependent upon the effects produced by concomitant renal disease. The blood analyses he had carried out showed that in about 20 per cent. of cases there was a pronounced retention of nitrogenous waste products similar to that met with in severe nephritis, but that in the majority the evidence of renal insufficiency was comparatively slight, while in about 25 per cent. of cases it was entirely lacking. It was therefore probable that, although renal defects were the primary cause of the retinitis in a small proportion of cases, and were possibly a contributory factor in others, they were not an essential feature of the ætiology.

Apart from persistent or intermittent hyperglycæmia the most constant chemical abnormality in Dr. Cammidge's experience had been a low calcium level in the fasting blood, distinctly pathological figures having been obtained in all his cases, except those in which the retinitis was of the "albuminuric" type, with pronounced albuminuria and serious nitrogen retention. There was no evidence that the low percentage of calcium in the blood of typical cases of diabetic retinitis was the result of an "acidosis"; and although in some instances it might be accounted for by an excessive loss of lime salts in the fæces and urine, there were others in which a normal fæcal ash and a normal excretion of calcium in the urine had been found. The fact that retinitis was rarely met with in diabetics before the age of 35, and usually occurred in patients who had suffered from a mild anapothectic glycosuria for many years, probably had a bearing on the question, for such patients seemed to be particularly liable to develop arterio-sclerosis and calcification of the peripheral vessels. The vascular lesions had been shown to resemble closely those produced experimentally in rabbits by prolonged feeding with cholesterol, and it was therefore not unlikely that the persistent lipæmia found with increasing frequency in elderly diabetics with the passage of time, especially if restriction of the carbohydrate of the diet had been compensated by a liberal allowance of fat, was the determining cause of the vessel changes and, maybe, of the deficiency of calcium in the blood, since there was experimental evidence that the metabolism of cholesterol and calcium were related, a fall of the one in the blood being associated with a rise in the other and vice versa. The blood analyses he had carried out had shown a low calcium and an excess of cholesterol in cases where the excretion of lime in the fæces and urine was not excessive, but a normal cholesterol and low calcium where examination of the urine and stools revealed an unusual loss of calcium by these channels, which seemed to indicate that the deficiency of calcium in the blood was not always due to the same cause. Whatever might be the exact origin of the condition in any particular case, there could be little doubt that the diminished coagulability of the blood consequent upon a poverty of calcium was one of the factors, and possibly the most important factor, in the production of the local hæmorrhages which were of such grave prognostic significance in diabetic retinitis. Further proof of the soundness of this conclusion was furnished by the results of treatment, for it had been found that the administration of lime salts by the mouth in sufficient amount to maintain the calcium content of the blood within the normal range prevented the occurrence of local hæmorrhages in simple diabetic retinitis, although not in retinitis of the albuminuric type. Control of the hyperglycæmia and glycosuria, either by diet or with insulin, had no effect upon the tendency to local hæmorrhages, but it usually brought about a rapid improvement in the vision of the patient. This, and the fact that retinal hæmorrhages sometimes occurred without previous symptoms in patients who had been sugar-free for long periods, suggested that the changes interfering with vision and the hæmorrhagic tendency were of independent origin, the former probably being the result of local defects directly induced by the diabetic state, and consequently yielding to antidiabetic treatment, *whereas the latter arose from general vascular changes* which were not a direct result of the metabolic disturbances induced by the diabetes, and therefore required independent treatment.

Discussion.

Dr. R. D. LAWRENCE said he was anxious to learn something of the mystery of the causation of diabetic retinitis. He had spent a good deal of time looking through notes of his cases to see what proportion of diabetic patients developed this retinitis, and what factors, besides the coexistence of diabetes, seemed to be behind its production. The hospital cases which he had looked up showed a higher percentage of retinitis than Dr. Cammidge gave, for about 11 per cent. of the diabetics were diagnosed by ophthalmic surgeons to have definite retinitis. His figures were, in fact, nearer to those given by German workers. No explanation seemed to have been given for the hæmorrhages and exudates in the eye. A study of the literature from the ophthalmological standpoint showed that many people denied there was such a condition as diabetic retinitis apart from arterio-sclerosis—i.e., the latter was always present in these cases. This was, he thought, laying too much emphasis on the vascular side. It was generally admitted that all these cases had a high blood pressure, also cardiorenal and vascular symptoms, as shown by the albuminuria and the presence of casts in the urine. Ruling out those cases, however, there remained a number in which nothing seriously wrong could be found in the kidneys or general vessels, and in which the blood pressure was not abnormally high. These latter were the cases which interested him most.

Dr. Lawrence said it was news to him that the blood calcium in these cases was considered important, and he would like to know what Dr. Cammidge regarded as a low figure (Dr. CAMMIDGE: 5·8 to 6·5 is the normal for whole blood). As to the cases which did not show ordinary arterio-sclerosis Dr. Lawrence had a suggestion to offer—namely, that the real damage in diabetes was that done to the endothelium of the vessels; there seemed to be a calcification in the mesial layer of the arteries, followed by its proliferation. This would be a very serious matter in the case of eye vessels. Once this had begun in the eyes of the diabetic there probably was never a return to the normal. Another possible factor in the causation of exudates and hæmorrhages was change in osmosis caused by hypoglycæmia. These changes were responsible for the production of cataracts in diabetics. Since the introduction of insulin he had noticed, following its use, a temporary swelling of the lens. Forty per cent. of the severe cases which he treated in this way showed misty vision for the first few days or hours while the blood-sugar was being brought to the normal level. He would welcome opinions on these two suggestions which he had put forward. The change seemed to be produced by prolonged diabetes more than by the immediate presence of sugar.

Lt.-Col. A. E. J. LISTER asked what was the proportion of cases in which the retinitis cleared up, and in what form and dosage the calcium was given. In India the condition was quite common, and the proportion of retinitis cases among diabetics was higher than the figure Dr. Cammidge gave. The age-incidence was lower in India than in Britain, but the Oriental aged quicker than the European.

Dr. CAMMIDGE, in reply, said his cases had been private ones, and he had only quoted cases as retinitis which were sent to him as such—he did not claim to be an expert in the examination of the eye. His figures might show a low proportion because the condition was pronounced in them all. He found it difficult to form decided views about the ætiology, but he was inclined to agree with Dr. Lawrence that the retinitis was not altogether due to the sugar. But he certainly considered that the œdema which interfered with the vision was due to the sugar, because the condition of the eye cleared up so rapidly when the patient was treated, especially now that insulin was available. *As to treatment, the subjects of* diabetic retinitis were generally either elderly or very old, and he had a strong objection to giving insulin to elderly people if it could be at all avoided, for they already had a certain amount of change in the heart muscle, and a rapid change in the amount of sugar going to the heart might have very serious consequences. If elderly diabetics could be treated by dieting they were much more comfortable, and they responded to the treatment quite well, though they took longer to do so. In some cases one was bound to use insulin, but care must be taken that the sugar was not rapidly reduced. In his practice the calcium in the blood was estimated as regularly as the sugar. The form in which he usually gave the calcium was as calcium lactate in an emulsion of liquid paraffin, the latter because most of these patients had some intestinal catarrh. Five, six, or seven grains a day was the dose; it was a prophylactic, and it was necessary for the patient to take it for the rest of his life. Recently he had tried the effect of vitamin D; in some he had tried parathyroid, but the results had not been such as to make it worth while to continue.

Sarcoma of the Iris.

Mr. H. B. **STALLARD** showed pictures of and described a case of leucosarcoma of the iris, which was under the care of Mr. W. S. Duke-Elder. The man, aged 69, complained of failure of vision in the left eye, and was thought to have a small tumour of the iris in the right eye. It had a nodular surface, and there were small capillary loops on it. The tumour appeared to be fixed to the iris. There were also striæ in the lens. Excision of the eye was declined, therefore Mr. Duke-Elder did iridectomy. A conjunctival flap was dissected out in the vicinity of the tumour, and the anterior chamber was opened by a keratome incision. This incision was afterwards enlarged and the tumour was removed with a good piece of iris on each side of it. It was composed of spindle-shaped cells, having an oval nucleus, and there was a marked absence of intercellular stroma. The blood-vessels had very thin walls, and there was complete absence of pigment cells and of pigment granules between the cells. Later the patient consented to have his eye removed, and serial sections of the globe revealed no other abnormality. Mr. Stallard had been able to find records of 21 cases of so-called leucosarcoma of the iris.

Mr. **TUDOR THOMAS** read a paper (by Mr. M. S. Mayou and himself) on a case of sarcoma of the iris, which appeared to have originated from a mole.—Mr. **MAYOU** said his first impression was that it was a cyst, because of the discoloration of the iris; there were posterior synechiæ, and the growth seemed to transilluminate, but Mr. Thomas's view that it was a malignant growth proved correct. The growth was spreading along the surface of the iris, and had egun to invade the ciliary body. The deeper rtions of the iris were very little involved.

SECTION OF THERAPEUTICS.

THE USE OF ERGOT.

A **MEETING** of this Section was held on Nov. 12th, with Dr. **PHILIP HAMILL** in the chair, to discuss investigations on the Proper Method of Including Ergot in the Pharmacopœia.

Dr. J. H. **BURN** opened the discussion. He said that his communication was a joint paper, the investigations having been carried out at the Pharmacological Society with the help of his colleagues there. The method used for standardising the various solutions was that of Broom and Clark, which depends on the power of ergot to reduce the contraction due to adrenalin in strips of uterine muscle. Dr. Burn emphasised the fact that the action of liquid preparations obtained from ergot depends on the presence of ergotoxine or ergotamine. Histamine is present in insufficient quantities in the usual liquid extracts to produce any effects. It was not easy to decide on a suitable standard for ergot. The method used with digitalis and strophanthin, that of mixing the various samples of the drug and using a preparation made from them when its activity had been ascertained, as the standard, was not altogether suitable here. The samples of ergot obtained from Spain and Portugal were much richer in ergotoxine than those obtained from Poland and Russia, nor did the quality of the samples necessarily remain constant for any given place. In the United States, however, a similar method of standardisation to that used for digitalis was followed. A mixture of several varieties of ergot was made and extracted, and the fluid kept for six months. The standard fluid thus produced contained, on examination, 0·03 per cent. of ergotoxine phosphate. Dr. Burn and his colleagues, in attempting to establish their standard, had at first excluded Polish and Dutch ergot from their experiments and had taken the mean obtained by use of Spanish ergot. This had worked out at 0·10 per cent. which was found to be too high a standard to be followed by pharmacists, and they had subsequently reduced it to 0·05 per cent.

Methods of Extraction and Deterioration.

Dr. Burn then produced some interesting figures to show the efficacy of the various methods of extraction of the drug at present employed. The use of water only, which was the method set out in the British Pharmacopœia, gave an ergotoxine yield of less than 0·016 per cent.—in other words it was practically inert. The German method of using 50 per cent. alcohol gave 0·02 per cent.; the Dutch method of using 50 per cent. alcohol with 1 per cent. tartaric acid, and the American method of using 50 per cent. alcohol with 2 per cent. of hydrochloric acid each gave 0·10 per cent. Other acids, such as citric, phosphoric, and boric, could also be used with 50 per cent. alcohol. Tartaric, citric, and hydrochloric gave the best results when used with 50 per cent. alcohol, and the figure they yield (0·10 per cent.) is about as high as can be obtained.

Dr. S. **WOKES** submitted observations on extraction and deterioration arising out of the work described. He said it was extremely difficult to extract the whole of the ergotoxine from any given specimen. He described the method of fractional percolation used in his experiments, showing that each fraction takes out successively less ergotoxine from the sample used. Spanish and Polish ergot seldom yielded less than 0·10 per cent., while Polish and Russian ergot usually give about 0·03 to 0·05 per cent. That is to say that Polish and Russian ergot are useless if the standard is to be maintained at 0·05. The minimum standard for these samples would be 0·015 and the maximum 0·025 per cent. If they are to be used at all, he said, the standard must be lowered and it is possible to reduce the extracts from good samples to this level. Dr. Wokes then went on to speak of the important question of deterioration. He found that a sample of strength 0·07 per cent. when kept in the incubator deteriorated rapidly; by the end of four weeks it had lost more than half its activity; at the end of nine weeks it had lost nine-tenths. A similar specimen kept in the ice-chest was slower in its deterioration; at the end of twelve weeks it had lost half its activity. A sample kept at room temperature lost its activity at a rate somewhere between these two. He said that ergotoxine phosphate (1 per cent.) in aqueous solution also deteriorates; kept in the ice-chest it is found to have lost half its activity at the end of six months. Similar results were obtained with ergotamine tartrate; and ampoules of 0·05 per cent. ergotoxine phosphate fell to half their strength in 24 weeks. Samples of powdered and defatted ergot appeared to be much more stable and took up to two years at room temperature to lose their strength. Dr. Wokes therefore advised that ergot should always be kept in the powdered defatted condition, to be made up into fluid form in small quantities as required. There was, of course, the possibility that the addition of some stabilising substances might prevent the rapid deterioration, and investigations were also being attempted along these lines.

Possibilities of Oral Administration.

Dr. **BURN** then returned to complete his remarks, and said that on the showing of the experiments described by Dr. Wokes the United States Pharmacopœia and the Dutch liquid preparations of ergot must be inert at the end of three months from their *time of issue. As it was improbable that the preparations* were ever used much before that period, and as the B.P. aqueous preparation was useless, one wondered how ergot had obtained its reputation as a therapeutic measure. It had, of course, been used in the first place because of the large number of cases of abortion occurring during epidemics of ergot poisoning. But in these cases the patients were taking the raw drug, not the extract, and it had had no opportunity of deteriorating. This, of course, raised the question of the use of ergot orally as a therapeutic measure. Clearly it could be released in the digestive tract and absorbed into the blood stream, but the question of rate was important. A series of experiments had been made on spinal cats, the blood pressure being recorded and the effects upon it of adrenalin and ergot noted; a certain number of cats who had received 1 g. of powdered ergot the previous night were examined. It was found that the reversal of the adrenalin action by the ergot (from pressor to depressor) occurred earlier in the cats who had had a previous oral dose of ergot than in those who had not. On the strength of these experiments Dr. Burn had formed the opinion that the rate of absorption is sufficiently rapid to be of use therapeutically. He thought that an injection of ergot after delivery could be followed up by oral administration daily during the puerperium where necessary, and indeed there might even be some reason to guard against a cumulative action.

The CHAIRMAN asked for experiences among those present in the use of ergot by mouth.

Dr. IZOD BENNETT said that the solid preparations he had used had always produced some effects, but had invariably been made up with quinine as well as ergot.

Dr. BURN said finally that there was some reason to suppose that the weaker extracts deteriorated less rapidly than the stronger, and that possibly the strong extracts lost their activity rapidly at first and subsequently became more stabilised. Experiments were being made to test this.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society, held on Nov. 11th, the chair was taken by Mr. DONALD ARMOUR, the President, and a discussion on the

RELATIVE VALUE OF THE DIFFERENT METHODS OF DIAGNOSIS IN GASTRIC DISEASES

was opened by Dr. J. A. RYLE. The methods of diagnosis applicable in diseases of the stomach, he said, were clinical, radiological, and chemical, with exploratory laparotomy where other means had failed. Gastroscopy had not established its claims. In every case without exception the clinical method was the most important, and all further investigations depended on inquiry into symptoms and ordinary physical examination. The introduction of accessory methods had led to a certain neglect of the older clinical methods, to a loss of clinical confidence, and a lack of appreciation of the scope of inductive reasoning based on the anamnesis. Judgments had been warped and wrong conceptions had grown through the misapplication of the newer tools. The expense of investigations was another argument for conserving clinical wits and curbing a natural wistfulness for the help of objective methods which, after all, were only final in selected types of case. The demand of a half-educated public for complete inquiries was a complicating factor, but if the profession complied with this demand it would bring discredit to medicine, do disservice to the public, and cease to maintain that breed of clinicians which had been one of the prides of British medicine.

The clinical study of the dyspeptic should include: (1) an inquiry into the personal and family history; (2) a very careful inquiry into subjective symptoms; (3) observations on physical and psychological *type; (4) a general overhaul of all systems; and (5) a* special examination directed towards the digestive apparatus. The collection and analysis of symptoms was as a rule the most useful and most important. Family history was of real value in duodenal ulcer and gall-stones, as well as in dyspepsias associated with general ill-health or psychological disturbances. Age, sex, occupation, habits, seasonal fluctuations of illness, and food or drug idiosyncrasies were all important factors. Worry, fatigue, and sedentary work were potent agents in gastric disturbance, while a dyspepsia occurring regularly in spring and autumn should suggest duodenal ulceration. Nervous and anxious or phlegmatic temperaments were associated with special types of gastric reaction. The general overhaul might reveal little or much, but the little might be as valuable as the much. A rosaceous rash might clinch the diagnosis of true gastritis, as a fixed pupil or absent knee-jerk would draw attention to the tabetic crisis. The routine investigation should include a note on the skin and musculature of the abdomen, the presence or absence of cutaneous hyperalgesia or local alterations of abdominal reflexes, the conformation and contours of the abdomen, and tender points or areas of muscle guard. The teeth, tongue, fauces, stools, and vomitus must be inspected. This lengthy survey would often save time and patience expended in experimental treatment.

Classification of the Dyspepsias.

Dr. Ryle grouped the dyspepsias as follows:—

1. *Habit dyspepsias*, including over-eating, under-eating, over-work, lack of occupation and exercise, insufficient mastication, and constipation.

2. *Nervous or psychogenic dyspepsias*, including ærophagy, exhaustion, worry and anxiety states, hysteria, hypochondriasis, and refusal of food.

3. *Toxic and infective dyspepsias*, including alcohol and tobacco, indigestion, oral sepsis, tuberculosis, anæmia, debility, and visceroptosis.

4. *Irritative dyspepsias*, including ulceration, chronic infections of the appendix and gall-bladder, special sense disturbances like astigmatism, and central nervous lesions like tabes dorsalis.

5. *Mechanical dyspepsias*, including pyloric stenosis, hour-glass stomach, chronic extensive ulceration, cancer, and certain complications of gastro-jejunostomy.

In the first three of these groups, which probably comprised more than half the total seen in consulting work, radiographic investigation and gastric and stool analyses were not indicated and did not give much assistance, except that a test-meal might be a useful confirmation of the diagnosis of a true gastritis. As a means of reassurance to the patient these investigations might be useful, but a meticulous overhaul, a simple explanation, and a vigorous reassurance were usually quite effective. In the two other groups, however, prompt accessory examinations were essential. In any case where ulceration, stenosis, or cancer was reasonably suspected the patient should have a careful X ray examination, including serial snapshots and a detailed report by the radiologist of his method, the times of examination, and the screen observations. If there was hæmorrhage or perforation, however, treatment should precede investigation. There must be absolute certainty of diagnosis when the decision lay between a medical and a surgical campaign. The radiological demonstration of an ulcer was the most accurate diagnostic evidence obtainable; there might be an active ulcer without occult blood, and anything from achlorhydria to hyperchlorhydria might be found in the test-meal of gastric ulcer. In duodenal ulceration the climbing hypersecretory curve occurred in 70 per cent. of cases and was a valuable aid to diagnosis and treatment. A high peak of acidity with rapid emptying contra-indicated gastro-jejunostomy, while a gradually climbing curve with delayed emptying favoured it. Test-meal and stool examination were of no positive value in reflex dyspepsias, but a full survey of the alimentary and bile tracts might be advisable or occasionally imperative. In general, therefore, accessory methods were of little positive value in functional disorders of the stomach due to general causes; they were often helpful in functional disorders due to extrinsic organic disease, and they were indispensable allies of the clinician in structural disease.

Radiological Examination.

Dr. G. H. ORTON claimed that radiographic examination was superior to all others in the diagnosis of organic gastric disease, provided that it was carried out by an expert with long experience. He showed a series of lantern slides supporting this claim. Very little reliance was now placed, he said, on the indirect evidence afforded by X rays—i.e., the information given by the type of stomach, rate of emptying, and peristalsis. The direct evidence, however, was very nearly 100 per cent. accurate in expert hands. Many of the ulcers shown in his slides were very small and would not be detected by a single or a casual view. The axiom that an ulcer on the lesser curvature produced an incisura on the greater curvature, due to spasm, did not hold when the ulcers were very small. The results of medical treatment should be checked by a very large series of exposures; often an ulcer would only show in one out of a very large number. Healed ulcers showed an alteration of the rugæ of the stomach; transverse ribbing was typical of the scar of an old ulcer. Duodenal ileus should be detected, as it tended to create ulceration, and after gastro-jejunostomy it caused jejunal ulcers.

The Fractional Test-meal.

Prof. E. C. DODDS sent a paper which was read in his absence by Dr. J. D. ROBERTSON. He maintained that the passing of tubes, collection of specimens, and washing out of the stomach were the most important part of the fractional test-meals, and that their delegation to inexperienced persons accounted for the alleged failures of the method. First of all it was essential to see that the stomach was empty before the test-meal entered it; the aspiration tube must be moved about and care must be taken to see that it did not get blocked by mucus. No matter how clean the resting juice, the stomach should be washed out with water after it had been emptied as completely as possible. A technique had been adopted by passing two tubes, down one of which warm water was pumped by a record syringe, while an assistant aspirated through the other tube. If there were obstruction or cancer, several pints of water would be required before the washing came back clean. Then a pint of gruel was given and specimens were withdrawn every quarter of an hour for two and a quarter to two and a half hours. Great care must be taken to see that the tube did not get diverted to the pylorus. Each specimen was gently aspirated, and then injected back again several times to ensure a uniform specimen. Dr. Robertson then showed slides illustrating the difference between a test-meal carried out by an experienced and by an inexperienced person. The results in the latter case were seriously misleading. A sudden drop on a smooth curve indicated that the tube had entered the duodenum. The analysis was comparatively easy; the important part of the technique of the test-meal lay in its collection. Its value lay in the certain diagnosis it afforded of pyloro-spasm due to ulcer, cancer, or functional disturbances, of achlorhydria associated with pernicious anæmia and of advanced cancer of the stomach. In pyloro-spasm there was a large volume of resting juice, a high total acidity and free acidity, and a slow steady rise right to the end of the test. In pernicious anæmia the stomach emptied very rapidly, there was a very low volume of resting juice and little disparity between the total acidity and the base line. In carcinoma there was a large volume of resting juice with high total acidity and complete absence of free hydrochloric acid; often the odour was foul and the colour dark. The disparity between total acidity and base line was very small, provided sufficient care was exercised in washing out the stomach. In a leather-bottle stomach the volume of resting juice was low, and the stomach emptied very rapidly; there was usually blood in the dark, foul, resting juice, and the disparity was not very great. It must be remembered, however, that in earlier cases of carcinoma there might be a normal amount of hydrochloric acid and the only suspicious points might be the foul resting juice and some blood. It was often difficult to distinguish between the achlorhydria of pernicious anæmia and that of benign achylia. To distinguish them, 1 c.cm. of a solution containing 0·75 mg. of histamine acid phosphate and 40 mg. of neutral red was injected subcutaneously at the end of the test-meal, and further specimens were taken every five minutes. Normally neutral red or free hydrochloric acid soon appeared in the specimen. The patient with pernicious anæmia gave no response to this histamine test—i.e., neither neutral red nor free hydrochloric acid appeared in the stomach. Histamine, however, should not be given if the blood pressure were very low.

Much controversy had centred about the significance of lactic acid in the stomach. Careful inquiry had shown that the qualitative tests for lactic acid were unreliable, but a quantitative technique had been worked out, and 46 per cent. of resting juices had been found to contain it. The conclusion reached was that lactic acid was not pathognomonic of cancer nor produced by the cells of the body.

Discussion.

Mr. A. J. WALTON, while agreeing that the clinical examination was extremely important, thought that it was impossible to arrive at a formula for assessing the relative merits of the various diagnostic methods, as their efficacy depended so much upon the skill of the investigator. He quoted a series observed by himself to illustrate the comparatively low percentage of positive diagnoses given by X ray examination in cases where a gastric lesion was revealed afterwards at operation. He would accept a careful clinical diagnosis of lesser curve ulcer in preference to an X ray report. Much publicity had been given of late to the opinion that no gastric or duodenal ulcer should be treated surgically unless stenosis was present, this dictum being based upon the results of medical treatment as confirmed by radiological examination. Barclay, however, had stressed the fact that ulcers under medical treatment would lose their œdema, and become invisible to X rays. The usual six months period of observation after medical treatment was far too short; it was necessary to wait a year or 18 months to be certain of cure. The test-meal had given a high percentage of positive results in ulcer of the pylorus and duodenum, but only 75 per cent. in carcinoma of the stomach. Its results were liable to be ambiguous in mixed cases of ulcer and carcinoma. The clinical examination was, therefore, more important in carcinoma than in non-malignant conditions, as both the X ray and the test-meal were liable to fail.

Mr. H. W. CARSON also stressed the value of clinical methods, especially of the estimation of muscular tone by palpation. He attached particular importance to the history. Of the ancillary methods he preferred radiography, which in some of the malignant cases that had been quoted would have settled the diagnosis in five minutes. X rays were superior to chemical methods in multiple ulceration, especially when ulcers were situated so high up as to be inoperable. Some high ulcers could not be diagnosed in any other way, and the method sometimes averted an unnecessary and dangerous intervention.

Dr. G. W. GOODHART did not consider the radiological method very superior to the chemical. The majority of patients did not suffer from gastric ulcer or carcinoma, the two conditions in which X rays gave the most information. The general practitioner, however, desired a test which would enable him to distinguish the functional case from the organic. Experts might be able to dispense with ancillary methods, but not everyone who treated patients had their experience, and unfortunately very little had been done for the non-expert. He asked whether the test-meal could give the physician any idea of how to treat a functional disorder; he, himself, believed that it could.

Dr. G. E. VILVANDRÉ denied the existence of functional disorder without an organic basis. A gastric disorder might depend upon extensive pulmonary tuberculosis. Students should be taught to use their hands and eyes, and to ask the patient intelligent questions; that was the only way in which the profession—as distinct from the experts—would learn to diagnose carcinoma in its earlier stages. The radiologist could detect a penetrating ulcer of the lesser curvature, but could not yet say whether it was malignant. If all such cases were to be treated by medical means only bad mistakes must inevitably be made

Dr. A. CAWADIAS said that gastric disease was not primary, but a secondary or even tertiary result of a general or metabolic disturbance of the body, and nothing but a clinical examination would determine the diagnosis of the whole individual. Of the ancillary methods, radiology was the most important. The test-meal, he thought, was on the wane owing to its poverty of positive information; it gave information of a part only of the function of the stomach. Recent physiological research, by showing the intimate correlation that existed between organs, had invalidated the old conception of local functional diagnosis.

Dr. WALTER CARR, to illustrate the danger of dogmatism, quoted a case where malignant disease of the stomach with a very ambiguous symptom-complex had eluded clinical diagnosis for a long time, but had been revealed largely by the chemical investigation of the resting juice.

Dr. W. S. C. COPEMAN maintained that the abandonment of the test-meal on the continent did not prove that it was of no value. However, a test which depended upon the status of the tester was not a practical one, as there were not enough experts to go round, and this might be the reason why it had fallen into disrepute. The clinician wanted to know whether the stomach was reacting to the stimulus of food in a normal secretory fashion, and this information might be obtained in other ways than by estimating the free hydrochloric acid, the secretion of which was controlled by many factors. The possibilities of technical error were equally numerous. A more practical test was the total chloride estimation, which showed variations no wider than those of the hydrochloric acid test and probably gave a more accurate indication of the secretory activity of the stomach.

Dr. GEOFFREY EVANS remarked that most patients who came to a consultant suffered from functional dyspepsias. Diagnosis should proceed along the ordinary lines adopted in organic disease, the first stage being the anatomical diagnosis and the second the physiological. The ancillary methods could provide much valuable information, and each had its own value. Radiology could determine in a functional condition whether the stomach was short or long, how quickly it emptied, and the condition of its peristalsis. Similarly, the test-meal could give information available by no other means.

Replies.

Dr. RYLE agreed that those who could not be experts in radiology and chemistry had better leave these activities alone, but all practitioners of clinical medicine must try to be experts in symptoms. The test-meal gave such varying results in functional disorder that it was valueless, but he tried to apply it in all cases in which he considered the possibility of operation. Hyperacidity caused no symptoms; pain and discomfort were due to other causes, such as tonus, peristaltic abnormalities, and tension; loose thinking about symptoms could only be abolished by studying them. The chief symptoms of carcinoma—anorexia, anæmia, and fever—were clinical, but the other methods should not be neglected.

Dr. ORTON said that none of the very small ulcers were malignant, and that only X rays could determine the size and position of the lesion. Speaking of test-meals with tetra-iodo-phenolphthalein, he quoted the saying that "one had to be very robust to be a patient nowadays."

Dr. ROBERTSON also replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

A MEETING of this Section was held on Oct. 25th, with Dr. J. LAIT, the President, in the chair.

Argyria.

Dr. F. S. BOURKE showed a man suffering from argyria who was admitted to hospital on August 12th suffering from a sore throat and pains in his limbs. He gave a history of syphilis, and so was sent to the venereal department. His colour at once attracted attention. He stated that he joined the Army in 1896 and contracted syphilis in 1897. He served in India until 1908. While he was there some of the men suffered from sore throats, and as he had seen them cauterizing their throats with silver nitrate, he did the same himself. He first used silver nitrate in 1908.

The PRESIDENT said he had never seen a case of argyria, which was now, he thought, very rare. It had been more common formerly, when silver nitrate was used for treating gastric ulcer.—Dr. CYRIL MURPHY said he had seen this patient on a previous occasion, and at that time the pigmentation had only extended as far down as the abdomen.—Sir JOHN MOORE mentioned that some years ago he had seen a case which was the exact counterpart of the one now demonstrated. His patient had used silver nitrate for treating gastric ulcer.—Dr. R. A. Q. O'MEARA said that little was known about the pathology of the condition. The silver was deposited not only in the skin, but also in the internal organs. The silver formed with the albumin of the tissues an insoluble substance which was deposited between the cells, but not in the cells. He thought that the blue colour was more apparent in the face because of the relatively greater blood supply to the skin of the face as compared with the skin of other parts of the body.—Dr. E. T. FREEMAN said that in India silver nitrate had formerly been used as an astringent for the treatment of tropical diarrhœa. Possibly this patient had been given some silver for this condition while serving in India, as well as what he had used himself for cauterising the throat.

A Case of Extrinsic Stricture of the Œsophagus.

Dr. R. R. WOODS reported the case of a man, aged 48, who was first seen early in August, having had dysphagia for two months.

At that time he could only swallow fluids slowly. He had glands on both sides of his neck and a lump in the right hypochondrium the size of an orange. The liver was enlarged and the spleen palpable. X rays revealed a mediastinal tumour and a stricture at the 7–9th dorsal vertebræ. Œsophagoscopy showed an extrinsic stricture 31 cm. from the teeth. His teeth were removed and a gland sent for section. The report stated that "if it was a tumour it could only be a lymphosarcoma."

The neck was treated with fluorescein and X rays as described by Copeman, Coke and Gouldesbrough (*Brit. Med. Jour.*, August 10th, p. 233). The glands seemed to remain stationary, but the patient had only one course before his death. The œsophagus was treated with radium by means of a special applicator which enabled fully screened radon (1·2 mm. lead) to be inserted while allowing a passage for liquids during treatment. He had two applications; the first (August 28th) was 5·35 mcd. in four days and the second (Sept. 28th) 8·71 mcd. in seven days. Half a drachm of fluorescein was given every second day by the mouth during treatment. Surface applications to the thorax: radon in lead box 1·3 mm. distanced 1 cm. Front 20 mcd. in six days, back 30 mcd. in four days, each at the rate of 1 mcd. per sq. cm. Although successive X ray reports showed that the tumour was increasing his swallowing improved rapidly, and the day before his death (Oct. 9th) he had fried fish, potatoes and bread and butter for his dinner.

Post-mortem examination, said Dr. Woods, showed two points of particular clinical interest—viz., fibrosis where the radon had been applied and desquamation of œsophageal epithelium round the position of the applicator. This seemed to be the result of a peeling dose rather than a radium burn.

The CHAIRMAN described the post-mortem findings in the case. There was, he said, a large mediastinal tumour which had caused the stricture of the œsophagus by external pressure. There was no intrinsic tumour of the œsophagus. The tumour had infiltrated the right lung in a massive way, resulting in its collapse. The right pleural cavity was filled with fluid. A large tumour mass was found in the region of the head of the pancreas, and another large mass about the size of a fœtal head involved the left kidney. The liver, spleen and suprarenals were free from tumour nodules. The tumour was a lymphosarcoma. Sections cut from the site of the radium application showed fibrosis and retrograde changes in the tumour.

A discussion followed.

Dr. WOODS, in his reply, said he thought that possibly the fibrotic changes in the tumour could be attributed to the radium. All through the radium treatment the patient was getting fluorescein at the same time, but whether this had any effect on the efficacy of the radium treatment, it was not possible to say.—The CHAIRMAN, in answer to questions, said he believed that the primary growth was in the mediastinum. The spleen did not show any cyanotic induration. He thought the fibrosis which had occurred was the result of the radium treatment.

Dr. A. R. PARSONS described cases of cancer of the stomach and duodenum, and Dr. A. B. CLERY demonstrated a specimen from a case of cerebral hæmorrhage.

ST. ASAPH JOINT HOSPITAL.—A new joint hospital [illegible] *six districts which has been erected at a cost of £11,000,* was opened last week at St. Asaph. During the proceedings it was stated that the temporary hospital had been well supported and was "killing the old Welsh prejudice against hospital treatment."

MEDICAL WOMEN'S FEDERATION.—At the autumn council meeting, held in Edinburgh from Oct. 31st to Nov. 2nd, a scheme for a national maternity service, drawn up by a special committee, was accepted after discussion and slight amendment. The dismissal of women from their medical work on marriage was discussed and the opinion was expressed in a resolution "that marriage should not constitute a bar to the appointment of a woman to any medical post, nor should it be a cause for the termination of her contract. Her ability to carry out such contract should be the only deciding factor." The inadequate salaries of the medical women in the employment of the post-office were discussed, and it was reported that the Postmaster-General had consented to receive a joint deputation of the Federation and the British Medical Association. The differentiation made in the salary paid to the woman deputy commissioner under the Board of Control for Scotland was also brought to the notice of the council; the work done by all the deputy commissioners is similar in every respect, yet the woman's maximum salary is considerably less than that of the men, and this maximum was reached by her in 1910. Representations in 1922 and in 1924 without result are to be repeated. Three new committees were appointed—viz.: (1) a standing committee on national health insurance; (2) a committee for the promotion of an improved women's health service for India; (3) a committee to deal with dysmenorrhœa amongst factory workers. A resolution was passed requesting the British Medical Association to consider the desirability of a common approach to the General Medical Council to suggest the appointment of an additional direct representative for England.

Reviews and Notices of Books.

SIR CLIFFORD ALLBUTT: A MEMOIR.

The Right Honourable Sir Thomas Clifford Allbutt, K.C.B. A Memoir by Sir HUMPHRY DAVY ROLLESTON, Bt., G.C.V.O., K.C.B. London: *Macmillan and Co. 1929. Pp. 314. 15s.*

THIS must have been a difficult book to write, for it is a fully dated commentary upon the very varied life-work of a man who kept but few letters and no diary, and who left behind him no personal reminiscences. But Sir Humphry Rolleston had the great qualities for meeting the situation of being closely associated with Allbutt in this most prominent accomplishment and of being also an intimate personal friend. Further, though Allbutt preserved on his side so little correspondence, those to whom he wrote in many instances treasured his letters and their contents have been of great assistance in a study of the man, displaying him as one with multifarious and great interests to the advancement of which he gave unsparingly splendid gifts of character and learning.

The life of Allbutt is here considered in three sections: the first (1836–61) covers early life and education, and reminds us of the valuable post-graduate training which Allbutt underwent after securing classical and science honours at Cambridge and before he decided to start practice in Leeds; the second (1861–92) covers 28 years as a consultant in Leeds and three years in London as a Commissioner in Lunacy; the third tells the story of his 25 years' tenure of the position of Regius Professor of Physic at Cambridge. The famous "System of Medicine" having been projected in 1893, this last division of the book contains a description of the troubles of editorship which Allbutt faced and dispersed by his industry and orderly methods as well as by his erudition. To this period also belongs some of his best-known literary work, while throughout the whole quarter of a century he was the acknowledged guide of his calling in medical politics. Nearly two-thirds of the book is occupied with brief accounts of Allbutt's intervention in matters of the first importance, literary, scientific, and practical, as they concerned the profession of medicine, and hardly a page in Sir Humphry's closely written narrative is without some reference, date, story, or letter serving to remind us of the personality and influence of the great physician. The book will find a large audience awaiting it.

EYE, EAR, NOSE AND THROAT.

A Text-book of Eye, Ear, Nose and Throat Nursing. By ABBY-HELEN DENISON, R.N., Graduate of Massachusetts General Hospital Training School for Nurses, Boston, Mass. London: Macmillan and Co., Ltd. 1929. Pp. 295. 12*s.* 6*d.*

THIS little book contains three sections, devoted respectively to the eye, the ear, and the nose and throat. Each section begins with a succinct but readable description of the anatomy and physiology of the organs concerned, followed by a short list of drugs and solutions with notes of the purposes for which they are employed. Next comes an account of appliances and nursing treatments, such as various forms of eye pads and bandages, and the methods of irrigating the ears, and this section is followed by a description of the usual operations, the preparation for them, and the complications which must be looked for, and, finally, the nurse's miscellaneous duties in the out-patient department. Much of this part of the book is in tabular form and, being in conformity with the routine of a particular hospital, is not necessarily directly applicable to others; but it will be found valuable for purposes of reference by all nurses undertaking this special work. We are astonished to see flax-seed poultices given as the regular treatment of aural furunculosis; and, in the chapter on drugs used in nose and throat diseases, "ephedrine

1 oz.," is obviously intended for a solution of ephedrine, the strength of which is not mentioned. Lack of accuracy in a book for nurses always has its dangers, though it is of less moment in a later section on mouth-washes, where the direction is given to dissolve one tablet of potassium chlorate in a quarter of a glass of water, the size of the tablet not being specified. The book closes with a sympathetic description of the function of the social service worker. It is provided with a good index, and may be recommended for the purposes at which it aims.

Your Nose, Throat, and Ears; Their Care and Health. By L. W. OAKS, M.D., and H. G. MERRILL, M.D. London and New York: D. Appleton and Co. 1929. Pp. 167. 5*s.*

THIS is, we are glad to note, in no sense a manual of home treatment; it is indeed but little concerned with the question of treatment, but aims at giving members of the public a general idea of the functions of the nose, throat, and ears, and of the ills to which they are liable. The authors have done their work well. They have laid stress, without being unduly alarming, on the dangerous possibilities of such conditions as continued hoarseness, and they have described the commoner affections with a fair degree of accuracy in untechnical language. We would have liked to see an account of the troubles which arise in nose and ears from bathing, and of the precautions which may be taken to prevent them, and we do not agree that spontaneous perforation of the drum produces the stellate appearance figured on Plate VII., or that such a perforation will probably remain permanent. But the authors have succeeded in avoiding most of the pitfalls which beset the path of those who would write a book on technical matters to enlighten the members of the general public.

BIOCHEMISTRY.

A Text-book of Biochemistry for Students of Medicine and Science. Second edition. By A. T. CAMERON, M.A., D.Sc. Edin., F.I.C., F.R.S.C., Professor of Biochemistry, Faculty of Medicine, University of Manitoba; Associate in Biochemistry, Winnipeg General Hospital. London: J. and A. Churchill. 1929. Pp. 482. 15*s.*

THERE is very little change in the second edition of this book, but certain errors have been corrected and the whole has been brought up to date. It deserves the serious attention of teachers of physiology and biochemistry, since it was not only amongst the first of the general text-books of biochemistry appearing in the English language, but is now one of the most popular. The author has treated the subject in a broad-minded way, which makes the book useful to the physiologist who wishes to study biochemistry, and to the qualified man or medical student who wishes to apply to medicine and pathology biochemical knowledge. The keenest critic would have to admit that even on highly debatable questions the statements here expressed are fair and accurate, so that the work is likely to retain a permanent place in the literature of biochemistry.

AIDS TO DERMATOLOGY AND VENEREAL DISEASES.

By R. M. B. MACKENNA, M.A., M.B., B.Ch. Camb., M.R.C.P. Lond., Hon. Assistant Dermatologist, Liverpool Cancer and Skin Hospital. London: Baillière, Tindall and Cox. 1929. Pp. 230. 3*s.* 6*d.*

IN this little book the author, who is the son of Dr. R. W. MacKenna, displays the happy knack of combining the synoptic with the discursive methods. The result is a readable and interesting review, which covers the subjects specified sufficiently both for examination purposes and the daily exigencies of general practice. Some valuable sections on X ray and radium therapy are included, while the chapter on purpura presents an original classification based (1) on defects of the capillary walls, (2) deficiency of the blood-platelets, and (3) defects of the blood-coagulation complex—a welcome departure from such ill-defined entities as purpura simplex and purpura hæmorrhagica. There are a few useful diagrams. Fig. 1 illustrates the structure of the normal skin, but omits to label, although it depicts, the basal or germ-cell layer. Dermatologists may not agree with the suggestion on p. 9 that a starch poultice should be left in situ for as long as 12 hours. The book provides a useful compilation.

THE PREVENTION OF DISEASE IN THE INDIVIDUAL.

Third edition. By KENELM WINSLOW, M.D., B.A.S., Attending Physician to the Seattle City Hospital and King County Hospital, Washington. London and Philadelphia: W. B. Saunders Company. 1929. Pp. 431. 12*s.* 6*d.*

FIRST published in America in 1916 this book has become deservedly popular, providing as it does a detailed practical guide for the layman capable of understanding simple scientific terms. The information given on matters of personal hygiene relating to diet and exercise is excellent. In the section dealing with alcohol the author takes a sound commonsense view of the whole position; he looks with disfavour upon bootleg liquor, one part of which is said to cause the same degree of drunkenness as ten parts of pre-prohibition liquor. The classical delirium tremens patient has disappeared from American hospitals; it is doubtful if drinkers of bootleg manufacture survive to develop the chronic effects of alcoholism. Germ diseases are well described. Considerable attention is given to tropical diseases, such as malaria, yellow fever, dengue, and cholera, as well as those with which we are more familiar in this country. The chapter devoted to the prevention of diseases of middle age is well written and will be useful, not merely to the middle-aged, but to those called upon to advise them on their methods of life. The chapter on the prevention of cancer is an excellent one which the layman will readily understand. The volume may be recommended to all who find themselves called upon to lecture or speak to the public upon the preservation of health and the prevention of disease.

GYNÆCOLOGIC TECHNIC.

By THOMAS H. CHERRY, M.D., F.A.C.S., Professor of Gynecology, New York Post-Graduate Medical School and Hospital. Philadelphia: F. A. Davis Company. 1929. Pp. 678. £1 13*s.* 6*d.*

THIS book is intended for the practitioner only and deals with the technical rather than the theoretical aspects of gynæcology. Provided that books of this kind are used by those with a sound knowledge of the basic principles of the subject their value may be great, but there is always a danger that readers may forget that technical dexterity cannot compensate for the absence of knowledge of the pathology of the disease it is proposed to treat. Great pains have been taken by the authors to make the book clear and simple. The description of operations has been restricted to one standard method which is given in detail. The work is lavishly illustrated by one of the best series of illustrations in the literature; these have been drawn by the author himself and accentuate the exact points which he wishes to make clear. An operation for complete prolapse is described which entails vaginal hysterectomy; the subsequent closure of the vaginal vault, it is claimed, tightens up the cardinal ligaments. It is difficult to imagine what happens to the ureters during the process. Wertheim's hystero-vaginectomy for carcinoma of the cervix is not described; radium seems to have completely replaced the radical operation in the treatment of this disease in America. The use of electricity in gynæcology is fully discussed and this section of the book should be consulted by British gynæcologists who seem to have neglected somewhat this weapon. An unfortunate misprint occurs in a table giving the dosage of stovaine for spinal anæsthesia at different ages; if this error were not detected the reader might be led to give ten times the correct dose to children.

This work will be read with interest and profit by those called upon to operate on the female genital tract.

HÆMATOLOGY.

Einführung in die Hämatologie. By Dr. A. VON DOMARUS, Direktor der Medizin, Abteilung des Städtischen Krankenhauses Berlin-Weissensee. Leipzig: Georg Thieme. 1929. Pp. 185. M.14.

THIS book begins with a good account in plain German of the methods used in the study of hæmatology. The three plates showing the blood-cells, normal and abnormal, are well reproduced. We note that the author favours the use of actual numbers as well as percentages of the different types of white cells. As an example of the error associated with the method more commonly used in this country he points out that if the number of white cells in a case of polymorph leucopenia is expressed in percentages one is given the impression that there is a lymphocytosis, whereas in reality the lymphocytes may be normal in number. In the pernicious anæmia section more prominence might have been given to the liver treatment and to the changes this brings about in the blood picture.

The book contains much information in a small compass.

SEX AND DISEASE.

By ROBERT V. STORER, M.R.C.S. Eng., L.R.C.P. Lond. London: Butterworth and Co. (Australia), Ltd. 1929. Pp. 131. 8s. 6d.

THE main purpose of this small volume is to assist the layman in the solution of sex problems and to explain the nature and dangers of venereal diseases. The subject is presented in a clear and concise manner. In discussing the pathological effects of these diseases the author has avoided the error of magnifying the dangers and thus of terrifying the nervous and worried reader. To those who are suffering from syphilis or gonorrhœa the volume conveys much sound information; the necessity for regular skilled treatment is stressed, and the results achieved by modern methods and remedies presented in an encouraging way. Dr. Storer lays stress upon the advisability of undergoing thorough tests for cure in gonorrhœa. A brief description is included of Australian public health measures for the prevention and treatment of venereal diseases.

GREEK MEDICINE.

By ARTHUR J. BROCK, M.D. London: J. M. Dent and Sons, Ltd; New York: E. P. Dutton and Co., Inc. 1929. Pp. 256. 5s.

THIS selection, illustrative of medical writers from Hippocrates to Galen, forms the volume on Greek medicine in the Library of Greek Thought, which is now being issued under the editorship of Dr. Ernest Barker. It is appropriately dedicated to the memory of Dr. Francis Adams of Banchory. The author modestly disclaims any pretentions to finished Greek scholarship, but tells us that he has been a student of Greek since boyhood, and that for the past 20 years he has been reading Greek medicine in the original tongue. All the extracts included here, except those from Aristotle, are his own translations. The first 34 pages of introduction are explanatory, and deal with Greek medicine before Hippocrates, the empiricists, Greek medicine in Rome, methodism, pneumatists and eclectics, Rufus of Ephesus, and Galen. Dr. Brock draws an interesting parallel between Galen and St. Paul. The Hippocratic selections include *inter alia* his views on such surgical conditions as dislocation of the hip and club-foot. These extracts are followed by an account by Thucydides of the pestilence at Athens, which seems to have been more like typhus fever than anything else. Next come short excerpts from Plato and Aristotle, while notes by Rufus of Ephesus on medical interrogation of patients and on anatomical nomenclature end the first part. The rest of the book is devoted to Galen, while a short appendix contains a description of the plague at Syracuse among the Carthaginians, 397 B.C., by Diodorus Siculus, and a discourse by Aetius of Amida, sixth century, A.D., on aneurysms.

The whole forms a fascinating volume and will be welcomed by medical men with an appreciation of ancient culture.

CLINICAL LABORATORY METHODS.

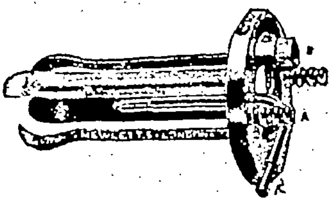
Third edition. By RUSSELL LANDRAM HADEN, M.D., Professor of Experimental Medicine, University of Kansas School of Medicine. London: Henry Kimpton. 1929. Pp. 317. 21s.

OF text-books of clinical pathology and laboratory methods there is nowadays no end. The present work stands well in the front flight and the appearance of a third edition will be welcomed by those who already know it. This book was designed largely for the American practitioner who apparently is able to spend more of his time in his "office" laboratory than his British colleague can afford to do. In this country its appeal will be mainly to the pathologist working single-handed in a small laboratory. The author confines himself strictly to procedures of proven practical value and for each of these describes one technique only. The notes given are lucid and concise and include accounts of certain techniques such as that for the determination of indican in the blood by the method of C. H. Andrews, which have up to the present not yet made their appearance in many text-books.

New Inventions.

THE VAGINOSCOPE.

UNDER this title I have introduced an instrument (here illustrated in the open position) which remedies many defects noted in specula hitherto in use. The vaginoscope, in its closed form, is of small cross section, and can therefore be introduced painlessly, the patient being in either the dorsal or lateral position. Illumination is provided by a bulb attached to a battery and flex by a long thin bent tube running in a groove along the lowest blade, the whole being removable for sterilising the instrument itself. A slight up-and-down movement at K makes or breaks electrical contact. Excellent visibility is thus obtained of the vaginal walls, the cervix, and fornices. By loosening screw-knob B), and then placing the thumb on peg (A) and the forefinger on (B) a single grip effects a simultaneous outward movement of the four blades resulting in a quick dilatation of the vagina. Sufficient dilatation having been obtained the screw-knob is tightened, thus locking the instrument. Additional expansion is produced by the bulbous extremity of the instrument, which not only acts as a retaining medium, but also enlarges the field of vision at the inner end of the vagina. No assistant is required to hold the instrument in place, and the hands of the examiner are left free to use additional instruments, &c. On completion of the examination for diagnostic or therapeutic purposes the screw-knob (B) is loosened; then gripping (B) and (C), a single movement suffices to close the instrument, which is then easily removable in its partially closed form. The instrument is a compact, self-retaining and self-illuminated speculum.



Messrs. C. J. Hewlett and Son, Ltd., 35–42, Charlotte-street, London, E.C.2, are the makers.

EDWARD BARON, M.B., Ch.B. Leeds.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 16, 1929.

THE SIGNIFICANCE OF VISCEROPTOSIS.

ALTHOUGH the group of symptoms associated with a dropping of abdominal organs was lucidly described three centuries ago by RICHARD BURTON in "The Anatomy of Melancholy," their cause still remains a matter of speculation, and our knowledge is little more than a commentary on associated conditions. No one has published statistics of the average duration of life in human beings with displaced stomachs and colons; or of their comparative effectiveness as members of society[1]; until this has been done we have no right to dogmatise. But much has been written on the subject, and we are indebted to Dr. HARRY BEDINGFIELD for a scholarly summary in a thesis presented for the degree of M.D. which has been appearing in the last two issues of the *Quarterly Journal of Medicine*. In this thesis the author has reviewed more than 640 papers bearing on the chronic invalidism associated with visceroptosis. Before the introduction of the opaque meal at the end of last century the position of the abdominal viscera during life was inferred from the lessons of post-mortem dissections and observations made in laparotomies. The introduction of formalin as a hardening agent illumined the topography of the abdomen, but the light was obscured by the medium through which it came. We do not know, for instance, how long in the daily life of any person the pylorus lies in the "transpyloric plane" of Addison. With the exception of its proximal and distal attachments—the duodeno-jejunal junction and the iliac colon—the bowel certainly appears to be a mobile and wandering inmate of the abdomen, and this fact, first shown by radiology, has given rise to a new conception of visceroptosis. Until the normal is defined it is impossible to detect the abnormal. There is as yet no consensus as to the normal limits of visceral mobility, while it is increasingly recognised that function is not necessarily impaired by abnormal position. It may be recalled that in "The Ship that Found Herself" the engines which had been built to work on clean steam in an upright position were able to carry on while lying almost horizontal and consuming a mixture of oil and dirty water. Radiology has shown the alimentary canal to possess something of the same adaptability. The stomach can empty itself in the usual time and without functional disturbance, even when the skiagram shows a high degree of dropping (CONRAN and MARKER), and the same holds for other parts of the alimentary canal. Herein lies the riddle of chronic intestinal invalidism. Though the radiograms in two cases may be almost identical, in one case there is pain and disturbance of function, while in the other there is none. Symptoms associated with enteroptosis may disappear without change visible in the radiogram.

Evidently in visceroptosis some other factor is necessary before the comfort of the individual is affected, but whether this factor is to be sought in a local morbid condition or in a bodily diathesis remains undetermined. Before the advent of radiology the local condition was regarded as holding the key to the problem, but this is not the modern view. Theories galore have been brought forward to explain what may be called the primary factor in the production of symptoms in chronic intestinal invalidism. BEDINGFIELD mentions over a score, several of which call for special comment. GLÉNARD, whose name is in France associated with the condition, propounded the mechanical theory in 1885, but modified it later as his clinical studies led him to suppose that the liver played a predominant part. In hepatism, as he called it, there is invoked an inadequacy of the liver cells, congenital or acquired, which may remain latent until called into activity by some factor such as infection or trauma, when the liver fails in its detoxicating action, and a poisoning of the bowel ensues, resulting finally in stasis. ARBUTHNOT LANE, who also regards stasis as the most potent cause of symptoms, has a different theory. In 1885 he noticed a band at the junction of the iliac with the pelvic colon which might, by angulation of the bowel, give rise to obstipation; the overloaded bowel, with its tendency to kink, produces a back-working which, by a series of analogous changes, would finally affect even the stomach; bands supporting the sagging bowel contract in their turn, producing further angulation and stasis, and finally an intestinal toxæmia is produced. GOLDTHWAIT, on the other hand, regards visceroptosis as due to bodily configuration, nervous symptoms being brought about by dragging on the solar plexus. A fourth school debits the causation of symptoms to a localised pathological condition, such as constipation, entero-colitis, appendicitis, adhesions, excessive mobility or fixation of the cæcum. Physiologists have commented on the lack of harmony in the interaction between the different parts of the autonomic nervous system, producing symptoms directly or through the liberation of chemical stimuli. None of these theories in its entirety has stood the test of time, and the treatment founded upon them, whether medical or surgical, has led to disappointment. Each new line of therapy has given good results in selected cases, and the impartial observer is forced to the conclusion that the causa causans still remains to be discovered.

Between mental reactions and the functional condition of the alimentary canal a relationship has long been traced, and this assumption has been amply confirmed by radiologists. One example is A. E. BARCLAY'S well-known observation of the sudden dropping of the greater curvature of the stomach following a shock due to the slamming of a door. The most casual student of the literature of chronic abdominal invalidism must be struck with the frequent reference to mental and nervous disabilities, and the frequent resort to some congenital explanation of the symptoms. Thus we have congenital inadequacy of the liver cells, congenital dislocation of the viscera, congenital malformation of the thorax leading to a low position of the abdominal organs, failure of normal development leading to defective visceral fixation, and, in our own day, congenital bands and membranes. For some time also it has been recognised, notably by H. C. CAMERON, that there exists in children a condition symptomatically analogous in its symptoms to that found in adults. Consideration of these three factors has produced yet another theory to the effect, stated in its most general form, that in visceroptosis some departure from normal mental functioning is fairly regularly associated with the departure from normal physical functioning. An attempt has been made to associate the nervous diathesis with a particular physical configuration, but the organic structure is so modified and altered in the course of time that rigid lines of demarcation are difficult to define, one group merging into another, and leaving a large unclassifiable borderland. Indeed it is doubtful if the bodily constitution remains the same throughout life. The inherited factors are continually being played upon by the stimuli of environment, and the individual at any moment is the resultant of these forces. Constitutional inadequacy may thus be regarded as offering the most plausible explanation of the chronic abdominal invalid. By this is meant a state of physical and mental make-up, congenital and possibly inherited, which handicaps the individual in his adjustment to the various environmental stresses. Such stresses as infection, a surgical operation, a love disappointment, the loss of a parent or friend, these are all shocks to which the constitutionally inadequate cannot react in a normal manner. A particularly potent factor is a low-grade infection, whether focal or generalised, continuous over a long time, as in tuberculosis. According to the degree of mental handicap, the individual may either triumph over, accept, or become the victim of his physical inefficiency. While this view offers a good working hypothesis, and is one which fits in most closely with observed facts, we may still feel that the whole truth has not yet been told. An obvious criticism is that we cannot adequately explain the greater incidence of abdominal invalidism in women. Two explanations for this are suggested: that girls do not (or did not) lead as athletic a life as boys, and that men have no strain corresponding to that produced in woman by menstruation and its disorders. Neither is very convincing, and, of course, severe cases are met with in males.

◆

PUBLIC HEALTH IN LOCAL LEGISLATION.

THE official index has just been published of the Local and Private Acts passed in the final session of the last Parliament—i.e., between November, 1928, and May, 1929.[1] In this period there were 96 Local and Private, as compared with 39 Public General, Acts. Though too voluminous and discursive for ordinary study, this local legislation contains, as usual, an experiment or two in public health and local administration which, if successful on a small scale, may some day be applied to the whole country.

We find, for instance, the Chester Corporation devising what may prove a valuable precedent for dealing with health conditions on house-boats. The Corporation is given power to prohibit the mooring of these vessels except at approved places, or unless suitable and sufficient sanitary conveniences exist or are provided, on the adjoining land. The Nottingham Corporation Act ingeniously applies to house-boats the "Tents and Vans" section of the Public Health Act of 1925. Thus by-laws at Nottingham may deal with the registration of house-boats, the prevention of river pollution therefrom by "sewage or any other offensive or injurious matters whether solid or fluid," and "the provision of such house-boats with such sanitary appliances as the Corporation may require." Elsewhere there are measures of flood prevention. The London County Council undertakes the duty of supervising and inspecting the banks of the Thames and overseeing the execution of such works as may perhaps prevent the recurrence of recent disasters. There is an echo of the latter in the Westminster City (Millbank) Improvement Act. Housing produces what seems a new clause in the Chester Act for "the provision of fixed baths in such classes of new dwelling-houses as may be prescribed." Tenants at Smethwick will have the advantage that the Corporation can put in pipes, wires and fittings, and can supply gas and electricity in houses where the occupier has asked for, and the owner has refused to give, these facilities. The amenities of town life are protected at Llanelly and Smethwick, where structural alterations can be ordered on complaint by the medical officer that smoke, gas, or vapour from outbuildings or washhouse chimneys causes a nuisance to neighbours. At Guildford, if buildings are being constructed or reconstructed, or if chimneys over 45 feet high are being erected, by-laws may require the deposit of plans showing the elevations and materials. If the proposed structure is likely to disfigure the neighbourhood, the plans are referred to a Standing Advisory Committee of three, consisting of a selected architect, surveyor, and justice of the peace, which can veto the proposal. This recalls a clause in the Bath Corporation Act of 1925. Another fresh precedent is the extended power at Chester to control the erection and painting of facia-boards, signboards, and signs.

In legislation directly concerned with health there has been a dearth of novelties lately. Blackburn, Bognor, Llanelly, and Oldbury, as well as Chester and Smethwick, obtained fresh public health powers in the past year, but most of the provisions are "common form." The control of ice-cream or potted food manufacture, the registration of ice-cream vendors and their premises, the restriction on the carrying on of business by infected persons, compensation to persons thus put out of employment, compulsory notification by doctors of food poisoning, the power to close Sunday schools during epidemics, the parent's duty to notify the head teacher of a child's infection, the extended definition of infectious disease, the obligation to furnish laundrymen's names—all these are nowadays as familiar as the provisions for dealing with unsound food, or for the cleansing of filthy premises. We noted last year in the Sheffield, Rotherham, and London County Council Acts the power to remove to hospital on a medical officer's written certificate and a magistrate's order persons who are either (*a*) aged, infirm, or physically incapacitated, and living in insanitary conditions; or (*b*) suffering from any grave chronic disease, if they are unable to look after themselves properly, or are not being looked after by others. This clause appears this year in the Blackburn and Smethwick Acts. So does the useful provision which allows the medical officer to enter (on a justice's warrant) any premises where a case of dangerous infectious disease is suspected. The two usual safeguards are added that entry must be made only between 7 A.M. and 10 P.M., and that the medical officer is not to examine anyone who is already under the treatment of a medical practitioner, except with the latter's consent. In this last proviso the Smethwick Act uses the words "registered medical practitioner," while the Blackburn Act merely says "medical practitioner." Does this mean that at Blackburn treatment by an unqualified person could prevent the medical officer from exercising his statutory power of entry and examination?

Some of the powers given to local authorities by Local Act seem trivial. It looks odd that a municipal corporation, for instance, should require the special authority of Parliament to charge anyone a fee for the use of an automatic weighing machine at public baths. The explanation lies in the restraining influence of the doctrine of ultra vires. Civic enterprise, however, triumphs over difficulties and gives a lead to the nation. Thus in many towns tests for motor drivers are now compulsory; so also is insurance by hackney carriage proprietors. Magistrates in London and elsewhere have protested the law's impotence to punish "joy-riding" (the practice of temporarily making off with someone else's car without his permission) till at length the Government has drafted a Bill on the subject. But Blackburn, Chester, and Smethwick had already made this practice a punishable offence. As with police matters, so with hygiene, Parliament seldom puts into a general Public Health Act any enabling clause which has not already appeared in local legislation.

CARDIAC STIMULANTS.

CLINICIANS and pharmacologists always seem irreconcilable about the so-called cardiac stimulants, and doubtless some of their difficulties arise from the varying nature of "heart failure." Circulatory collapse may be attributable to a breakdown of the heart muscle, of the arterioles or capillaries, or of the vasomotor centre. Thus it is that brandy, for example, by reflex stimulation of the medullary centres or by vaso-dilatation of the peripheral arterioles may improve the action of a labouring heart, though as a direct stimulant of the heart muscle it has no value. Similarly, strychnine has little or no direct action upon the heart muscle—Prof. J. A. GUNN [1] does not think it has ever saved a life—but it has an action on the central nervous system and the vasomotor centre, and in this sense may perhaps be called a circulatory stimulant. Pituitrin is another drug which has no action on the heart itself but it is to be regarded as truly a stimulant, because it causes a powerful contraction of the arterioles and probably of the capillaries. The claims made for camphor and its numerous compounds rest on a different foundation, for it is often said that they have a direct effect upon heart muscle. For this reason they have been very widely used in heart failure, especially on the Continent.

During the last sixty years Prof. P. TRENDELENBURG,[2] of Berlin, and his assistants have been studying the activity of some of these substances in experimental conditions of cardiac and vascular insufficiency. Like other workers he has found that their action is only to be detected in a failing heart, since the optimal activity of a normal heart apparently cannot be improved by any of the substances which he has tested. The effects of digitalis and strophanthin, for instance, can only be seen in the damaged heart and TRENDELENBURG draws attention to the contrary actions of adrenalin and ephedrine in health and disease. With a healthy heart these drugs constrict the arterioles so strongly, and the peripheral resistance is thereby so greatly raised, that the cardiac output per minute actually falls; the glucosides of digitalis and strophanthus cause far less vaso-constriction and thus produce less resistance to the heart's action. With an "insufficient" heart, however, adrenalin can directly stimulate activity so that the volume pumped through in a minute increases and the pressure in the arterioles falls. When the heart was experimentally damaged either by gradual exhaustion or by suitable poison—e.g., histamine or oxidised salvarsan—TRENDELENBURG was unable to show that, in therapeutic doses, the preparations containing camphor which he examined were of any use in reducing cardiac insufficiency; some even increased it. But when heart failure was produced experimentally by asphyxia from paralysis of the respiratory centre, these camphor compounds were able to restore the respiration and in course of time they regularly overcame even the severest cardiac insufficiency. This was especially obvious when the respiratory centre was paralysed by morphia, and less so when chloral hydrate was used. A purely "vascular" failure cannot easily be produced in the laboratory, but in this type of insufficiency the camphor derivatives again seemed to be entirely inactive; while adrenalin and ephedrine, as would be expected, were able to restore the circulation to normal conditions. Digitalis and strophanthus were only slightly active.

Purely arteriole or capillary failure must be uncommon clinically, because circulatory failure usually comes from a combination of vascular and cardiac factors. In such combined failure a cardiac stimulant should both improve the heart's action and constrict the peripheral vessels. Obviously the cardiac stimulation must not be less effective than the raising of the resistance from peripheral constriction, for if the blood pressure is raised more than the heart is stimulated the circulation will be hindered rather than assisted. This may sometimes happen when adrenalin is used—since the associated cardiac improvement may not be great enough to overcome the increased blood pressure—and it must be a constant result of injecting camphor compounds if it is true that they do nothing to remove muscular failure of the heart and only have the effect of increasing the resistance against which it is acting. TRENDELENBURG's research suggests that camphor preparations are actually harmful in heart failure. At best they are inactive except where the conditions are such that by stimulating the respiratory centre we can remove the cause of failure—that is to say, when we are faced with lack of oxygen or excess of CO_2.

FOR VALOUR.

THE armistice was signed ten years ago and the entrance upon a second decade was marked by the action of the Prince of Wales in presiding over a dinner to V.C.'s given in the Royal Gallery of the House of Lords on Saturday in last week. The dinner was organised by the British Legion and 321 of the holders of the Victoria Cross, representing all parts of the British Empire and all levels of social rank, met, having the common distinction of proven valour and the common desire to assist the ex-Service men in need, and to help the widows and dependents of those who gave their lives in the Great War. The Order was instituted at the close of the Crimean War, and there are alive some 400 holders of the Victoria Cross. Of these 321 were present at the dinner, a high proportion indeed when the difficulties of travel over the distances of the Empire are remembered, and the possible age and infirmity of some of the veteran wearers of, in the graceful words of the Prince of Wales, this Most Enviable Order. Enrolled in the Order are 14 medical men, of whom the following were present at the dinner: Major W. B. Allen, R.A.M.C., Colonel J. Crimmin, I.M.S., Captain B. Hutcheson, Can. A.M.C., Colonel E. T. Inkson, R.A.M.C., Lieut.-Colonel F. S. Le Quesne, R.A.M.C., Major-General Sir Owen Lloyd, E.P., and Lieut.-Colonel J. H. Reynolds, R.A.M.C. Corporal J. J. Farmer, Army Hospital Corps, was also present.

Annotations.

"Ne quid nimis."

A NEW RESEARCH HOSPITAL.

A DRASTIC change in the scope and purpose of any charitable institution must have parliamentary sanction and past subscribers may be assured that this would be withheld unless the alteration was warranted by a change in the needs of the population served. The fact that an Enabling Act was passed in May of this year, allowing responsible authorities of the Mount Vernon Hospital, Northwood, to use their lands and investments for the investigation and treatment of malignant disease instead of for diseases of the chest is an indication of such a change. In recent years the establishment of sanatoriums by local authorities has so diminished the number of patients applying for admission to the hospital that its council, with the full consent of the medical staff, sought and obtained permission to turn their efforts in a new direction. A scheme of work and development, framed with the help of experts, has been generally approved and is being put into speedy effect. The council of management of the hospital on which the medical staff is represented is being assisted by an advisory committee whose duties will be to give advice on the staffing of the hospital, on medical and scientific matters, and on the forms of treatment and research to be undertaken in the hospital. The new organisation differs in many important points from that of hospitals not primarily dedicated to investigation. A whole-time director of research is to be appointed to devise and coördinate schemes of work and the appointments of the honorary staff will be subject to annual consideration in accordance with the particular object of the hospital's research into various treatments for malignant disease. The survey of the history of this hospital and the reasons for its reconstruction, given on another page, is of more than local import. The same sequence of events might equally well have occurred in the life of any hospital designed to treat cases of infectious disease which are now for the most part being dealt with effectively in rate-supported institutions. Some will regret the change, but it may be a prototype of other changes and may point the way to the sound allotment of work between voluntary hospitals and those organised and supported by the local authorities. Routine treatment of disease by established methods can be carried out safely in any well-conducted hospital. The critical investigation of pathological processes and the assessment of the scope and limitations of methods of combating them is essentially work to be carried out in a hospital designed for the purpose. Medical students would, in an ideal state, have access to both types of hospitals, though not necessarily at the same stage of their careers. The conversion of the Mount Vernon Hospital to other purposes from those which it was intended to serve is not likely to be an isolated one.

ERROR IN DIFFERENTIAL BLOOD COUNTS.

THAT even in the most carefully prepared blood smear the white cells are far from being evenly distributed is recognised by everyone who has ever looked at such a preparation. That the various classes of white cells alter in their distribution in different portions of such a smear is well known to all who study them with any closeness. And that these facts must have a disturbing effect in a differential count of white cells is self-evident. Most workers have been content to do as best they can by the random selection of a few fields in a smear; others, following Naegeli, have tried to reduce the error by counting up to a thousand cells. Meanwhile, the laws governing distribution of the white cells in a smear have not come in for much careful consideration, and this is an omission which Curt Gyllenswärd, of Stockholm,[1] has tried to remedy. His results are reported in a very long paper which bristles with formidable calculations and should be consulted in the original by those interested. In brief, it may be said that he condemns the cover-slip method of preparation, and recommends that form in which the blood is smeared on a microscope slide by drawing a second slide along its length. In such preparations, however, the smaller cells tend to be deposited more quickly than the larger cells as the movement of the blood over the receiving slide decreases. The result of this is the formation, at the top and bottom of the slide and in the "tongue" at the end, of "zones" of lymphocytes, neutrophiles, eosinophiles, and monocytes. Counts conducted in these zones may show a relative distribution of the different classes of cells very different from that which obtains in the circulating blood. To avoid the influence of such zones Gyllenswärd recommends that in making a differential count the first and the last five millimetres of the smear should never be included, and that the count should be made on the central portion of the slide in transverse travels. If these precautions are taken he finds no advantage in including more than 300 white cells in the count.

BISMUTH IN THE TREATMENT OF SYPHILIS.

EVER since bismuth was introduced into the treatment of syphilis in 1921 it has been regarded almost universally as a valuable spirochæticidal drug. From time to time, however, a voice has been raised to question the advisability of using it in place of the older remedies, mercury and arsenic. In 1927[2] Dr. T. Anwyl-Davies discussed the action of bismuth on the *Spirochæta pallida* and, following the conclusions of W. Kolle and his collaborators, declared that bismuth had no direct curative action on the infection but merely inhibited the disease. Kolle's experiments and Anwyl-Davies's conclusions were discussed and strongly contested by Dr. C. Levaditi and Dr. L. Fournier.[3] We publish this week and last two further papers on the subject and a report of the discussion at the Venereal Diseases Section of the British Medical Association at Manchester last July. Dr. T. M. Ling has been working at St. Thomas's Hospital with bisoxyl, a suspension in water of bismuth oxychloride and chloretone. Subcutaneous injection of this preparation does not lead to the persistent pain and swelling characteristic of many forms of bismuth, and Dr. Ling has found it extremely useful in congenital syphilis, especially in lues tarda. He suggests that the spirochæte can acquire resistance to arsenic and mercury after prolonged treatment, and that in cases of this kind bismuth, without causing any untoward symptoms, will render serologically negative a fair proportion of apparently Wassermann-fast patients. Prof. H. Ritter and Dr. C. L. Karrenberg have been working at Hamburg with intramuscular injections of bismogenol, a suspension of a bismuth compound of a highly valent oxybenzoic acid in olive oil. They have found this eminently satisfactory, and declare that it has an abortive action on the disease. A number of patients have been treated by bismuth exclusively.

The case for bismuth is strengthened by these new reports. Prof. Ritter and Dr. Karrenberg suggest that many of the objections alleged against it depend on the very inadequate knowledge that the physician has of the exact amount of bismuth metal he is giving and its fate in the body. They also point out that the criteria for a successful antisyphilitic remedy are by no means standard. The amount of bismuth varies extraordinarily in different preparations and in different batches of the same preparation. The rapidity of absorption varies with the mode of application, the solvent or suspension medium, the concentration and the size of the particles. Some reports base their claims for success on rapid disappearance of the spirochætes, others attach more importance to the serological changes, others again to the clinical progress or alleviation of obvious symptoms. Most people seem to agree on the relative harmlessness of the most recent bismuth preparations compared with the quite grave risk attaching to arsenic and mercury administered in spirochæticidal doses. Very little is known of its mode of action. It is not a direct spirochæticide, as the amount in the blood at any time is never great. According to Dr. Svend Lomholt, the best technique for securing regular and uniform absorption is to maintain over a long period a high concentration in the body. The choice of preparation among the many which have been placed on the market and the estimation of the danger-point, are not easy matters. Dr. Lomholt placed the daily dose at about 0·5 mg. of bismuth metal per kilo of body-weight, but laid down that axiom which it is so important to remember in these days of standard treatment; every patient must be treated as an individual according to his own particular circumstances. There is a general consensus of opinion that the treatment should not be painful if the technique is good.

[2] THE LANCET, 1927, i., 148, 199.

[3] Ibid., 1928, i., 692.

From the differences of experts no general conclusion can at present safely be drawn. A great deal of painstaking research is required to determine the factors which influence the absorption and retention of bismuth in the human body. Only those who have considerable experience of all the antisyphilitic remedies are justified in using any one to the exclusion of the others in any particular case. They act differently and each has its own values and dangers. The syphilologist must keep all three metals in his surgery, and continue to rely principally upon his clinical sense for the decision as to which and what proportion of each shall be administered in any case. Meanwhile he looks to the laboratory worker to furnish him with precise information about the pharmacology of his drugs.

TONSILS AND ADENOIDS IN FRANCE.

IN this country for many years the great majority of surgeons operating on the tonsils have aimed at complete removal, either with the guillotine or by dissection. If a portion of the tonsil remains the operation is considered to some extent a failure, and indeed septic trouble in old stumps is common enough to suggest that complete operation is advisable. To perform this ablation with enough certainty, and at the same time to secure efficient hæmostasis, it is necessary that the patient should be perfectly quiet. Hence general anæsthesia is almost always employed here for children, although local anæsthesia is being used more and more for adults. But practice of this kind differs widely from country to country. The *Vie Médicale* recently asked a number of laryngologists whether they removed tonsils and adenoids with or without anæsthesia; if under anæsthesia, what method was most advisable; and, finally, how they dealt with adults. The twenty-one replies[1] show that they do things differently in France. For children of tender years, below an age which varies from two to five years, the large majority of operators use no anæsthetic, either general or local; for older children the proportion is almost exactly reversed, a general anæsthetic being preferred by about two-thirds of those answering the queries. It may be noted that some of those who condemn the operation without anæsthesia do so very strongly on the grounds that it is inhumane, that it does not allow careful operation, and that it makes children so frightened and suspicious that subsequent medical examination and treatment become very difficult. These are considerations which receive full weight on this side of the Channel. For adults local anæsthesia is generally recommended, only two preferring a general anæsthetic; infiltration with a solution of novocain is the method usually employed. Ethyl chloride is the general anæsthetic employed almost exclusively, but it should be remembered that rapid operation is the rule, and that complete tonsillectomy is not usually its aim, or its result. Although this subject did not come directly into the questionaire, five operators said that they performed tonsillotomy, not tonsillectomy, in children, and two that they did so also in adults.

LONDON SUBWAYS.

THE urgent need to inquire into the cause of London traffic fatalities, especially among children, is referred to in the annual report of the Coroner for the City of London and Southwark. Dr. Waldo points out that during recent years some third of the deaths caused by traffic fatalities have been among children and young persons. More than ten years ago, at Dr. Waldo's suggestion, the Borough Council of Southwark adopted the system of providing crossing places at certain fixed spots, the places being indicated by signs and directional notices, while school teachers were asked to explain to children the whereabouts and uses of the provision. The results were satisfactory, and many municipal councils have followed the example of Southwark. In several places in London where the channels of busy traffic decussate subterranean passages are now employed, and more subways are projected, despite the huge expense of their construction. But these subways make for public safety and must not be confused with the subways for the passage of gas and electrical mains which, in another part of his report, Dr. Waldo regards as a proper subject for Government inquiry. Referring to recent explosions and floodings, whose occurrence is in the memory of all metropolitan dwellers, he considers that the risks run by the community are great, seeing that in 1928 the explosions in electrical manhole boxes in the City numbered six, and in 1927 no less than 14, while no satisfactory scientific explanation of the accidents is forthcoming. That the London County Council is fully aware of the situation can be assumed from the announced intentions of the General Purposes Committee of the Council following upon a report of an official inquiry into the great Holborn explosion. The General Purposes Committee suggests that the Council should give effect to the recommendation of the committee of inquiry regarding the ventilation of cellars and vaults constructed under streets and connected with buildings, and that the necessary amendments to the London Buildings Act should be secured.

THE CONTRIBUTION OF MEDICINE TO INDUSTRY.

A REPRINT[1] of the Shaw lectures, delivered by Sir Thomas Legge in the early part of the year, confirms the impression then gained[2] of the unfolding of a romantic story in industrial medicine. Certain incidents are found to stand out with prominence. First comes the fact that lead poisoning in industry, whether in the potteries or in the white-lead trade, has been robbed of its terrors by the Shaw lecturer's discovery that it was caused by breathing lead dust and by his quiet insistence upon preventive regulations based on this discovery. Here is enough to earn the gratitude of his generation, and we may sympathise with him in the rejection of his advice to the Government to abolish lead poisoning from its last stronghold in the house-painting trade. Next may be placed the success achieved in freeing the woolcomber from the danger of anthrax, an old-time enemy, through the disinfection of all suspected wool as it arrives in this country. To this subject Legge devoted his Milroy lectures over twenty years ago. Last we would mention the prominent part he played in establishing methods for extending compensation to industrial diseases, which have been widely copied by other nations. He stresses, as a Parliamentary debate last week stresses, the enormous preponderance of claims arising from coal-miners for conditions peculiar to their occupation; but coal-miners are not protected by the Factory Acts which Legge had to administer. Yet, notwithstanding the striking results attained by appointing medical inspectors of factories, of whom Legge became the first in 1898, no medical inspector of mines was created until two years ago, after the connexion of the Ministry of Mines with the Home Office had been severed for ten years, and then in response to representations from the Medical Advisory Committee of the Ministry. There is still work enough for a medical inspector of mines to do but, as Legge asks in his Shaw lectures, what might not have been accomplished if the appointment had been made more timely?

THE DANGERS OF CONSERVATIVE DENTISTRY.

THE evolution of dentistry from a surgical to a preservative art was hailed in the early part of this century as a triumph of science over mere operative zeal, and conservative dentistry was the aim of every conscientious practitioner. Every tooth which could by any means be made into a useful mechanical instrument was scrupulously preserved, and a mouth full of teeth whose pulp had been killed and extracted was passed as sound provided the gums seemed healthy. The application of radiological means of diagnosis to dentistry and the correlation of areas of rarification with pathological conditions, not only local but general, has destroyed the confidence of both medical and dental professions in such decisions. In America especially, according to Dr. Boyd Gardner, who is head of the dental section of the Mayo Clinic, it is now becoming recognised that the surgery of the mouth has been unduly belittled. In a lecture given in London at the Royal Dental Hospital on Nov. 4th, he explained that in his clinic the dental student is instructed when he looks into a patient's mouth not to think first what could be done in the way of a filling, but to have regard to the cause of the condition. The removal of foci of infection shown by radiological examination had been followed by the clearing up of general disorders such as ulcerative colitis and even of certain types of arthritis. Dr. Gardner urged the desirability of taking radiograms after as well as before any operative measure. At the Mayo Clinic exposures were standardised, so that work in the dark room could proceed with almost mechanical regularity.

The value of X rays in controlling treatment is now established in this country. Many dentists have installed apparatus next to their consulting-rooms and the convenience to the patient of such an arrangement is unquestionable. In a lecture delivered to the British Institute of Radiology on Nov. 4th Dr. J. F. Brailsford claims that the most helpful information will be obtained when the radiography is done by an impartial observer. In his view the radiogram and its interpretation should hold the same position to the patient's medical adviser, dental surgeon, and the patient as the auditor's report does to the directors, staff, and shareholders of a company. They should provide the doctor with independent evidence of the condition of the patient's teeth, particularly that which is likely to have a bearing upon his general health, and they should give the dental surgeon support in dealing adequately with any lesion which may be present. Dr. Brailsford calls attention to the embarrassing position of the physician called in to see a patient suffering from what he believes to be septic absorption, possibly from teeth, when he is told that they have already been examined radiographically by the dentist and reported to be sound. But surely this a question only of interpretation of radiograms; it calls not for a further X ray examination which, as Dr. Brailsford rightly contends, would involve the patient in unnecessary expense, but for inspection of the results of that already made in consultation with the dentist. Admittedly, whoever takes the radiograms, there is no longer justification for the wholesale extraction of teeth without X ray examination. Dr. Brailsford points out that a doctor's plea for such extractions is based on his experience that this treatment results in alleviation of certain symptoms, and that equal success attends the extraction of only those teeth shown by the radiogram to be septic, when the patient is spared the digestive disturbances often experienced by edentulous patients. The question resolves itself into the problem of interpretation of dental radiograms. Mistakes in interpretation in the past have been due to lack of experience or knowledge of photographic and radiographic technique, or of the anatomy and pathology of the part. A radiogram may be so poor that the most experienced cannot interpret it; on the other hand, it may be excellent and yet convey little or no information to the inexperienced observer. Dr. Brailsford showed a series of lantern slides illustrating pathological conditions of the teeth and jaws and of errors of interpretation.

The technique is now well standardised and the correlation of the radiographic appearances with clinical conditions has been more easily and firmly established than that of lesions elsewhere in the body. For example, a large series of post-mortem examinations is required before mediastinal radiograms can be properly interpreted, but extraction of a tooth is usually sufficient to show how accurate has been the diagnosis of an apical lesion. The radiographic signs are there for all to read, and it is only necessary to remind enthusiasts that symptoms do not always clear up when the tooth is removed.

SUPERSTITION.

SUPERSTITION is the seed of enlightenment, the negative aspect of an apprehension of things beyond present knowledge. It holds all the truths of science, but holds them so fast that sometimes it seems far more the enemy than the friend of progress. The shadowy borderland between folklore, religion, and psychology has been all too little explored, but will prove a most fruitful field for investigation by the psycho-ethnologists of the future. Sir Robert Armstrong-Jones selected Superstition as the subject for his presidential address to the Psychiatry Section of the Royal Society of Medicine on Tuesday last. He was able to illustrate his remarks by pointing around him, for the meeting was held in the Wellcome Historical Medical Museum where the outward and visible signs of the superstitions of past and present are collected in profusion. On the previous evening the Curator, Mr. L. W. G. Malcolm, had been speaking to the Egypt Exploration Society on Egyptian Medicine and showing how the superstitions of the Egyptians had contained the germs of much that we now recognise as scientific knowledge. Death and disease they regarded as unnatural and abnormal, due to possession, and the prescriptions in the papyri are prescriptions not for curing but for banishing, driving out, or terrifying the disease. The very multiplicity of the prescriptions is evidence of their unscientific nature, yet among them were some which contained appropriate drugs, and as these in time superseded their less successful fellows, so the magician gradually became a physician and the Egyptians groped their way towards a rational pharmacopœia. Through a jumble of magic and sorcery, said Mr. Malcolm, we can trace the foundations of Grecian scientific thought, and especially does civilisation owe to the Egyptians that favourable attitude to anatomy which resulted from the practice of mummification. From the Egyptians Sir Robert Armstrong-Jones traced the threads of superstition through Greeks, Romans, and Scandinavians to Anglo-Saxon and modern times, but he had no kind word to say for it. Psychologically he described superstition as suggestibility, based upon fear, and he condemned it as no innocent mistake but a wilful and shameless belief contrary to the laws of nature, to experience, and to common sense. This may certainly be applied to those who cling to superstitions or conventions when there is at hand the means of rational apprehension, but when the primitive mind is striving with inadequate equipment to grasp an idea beyond its capacity to understand, superstition may be but the stepping-stone to knowledge. The curious thing about superstitions is that they so often contain, buried deeply in apparent nonsense, the germ of the truth. Kipling has illustrated this in his tale of Nicholas Culpepper who, for the most fantastic astrological reasons, set about destroying rats as a means of combating the plague and was more successful than the half-educated scientific man of his time. Quaint beliefs still hold the field in many departments of life and medicine where knowledge has yet failed to give full illumination. We shall do better than our fathers if we investigate them with sympathetic interest, rather than despising them as foolish or harrying them as evil. Explored with intelligence they are apt to yield, as several courageous investigators have shown, an unexpected treasure of new understanding.

INFECTIOUSNESS OF TUBERCULOSIS IN CHILDREN.

WHILE the view that tuberculosis is essentially an infectious disorder is gaining ground it is generally held that only open cases of tuberculosis, with tubercle bacilli in sputum or excreta, are a danger to their associates. In children it is so difficult to obtain sputum for examination that the question of individual infectivity is a difficult one to settle. Dr. Vlademar Poulsen, of Copenhagen, has recently investigated[1] 67 children, ranging from 2 months to 8 years of age who gave a positive tuberculin reaction. His method of obtaining sputum was that first introduced by Meunier in 1898, and revived at the present day by P. F. Armand-Delille and his pupils, which consists in washing out the fasting stomach in the morning with 200–300 c.cm. of sterile water, centrifuging the result and staining the deposit for tubercle bacilli after Ziehl-Neelsen. Another portion of the sediment may be inoculated on Petroff's medium or injected into a guinea-pig if further confirmation is desired. In this way 20 out of 67 children were found to have tubercle bacilli in the wash-out containing all the sputum swallowed overnight. The age distribution of these cases with positive findings was of interest; every one of 14 cases under 1 year of age gave a positive result, a finding in keeping with the generalised nature of tuberculosis at this early period of life. In older children positive results were obtained less frequently; over 3 years of age only two children had tubercle bacilli in the wash-out, of whom one had phthisis with cavitation and the other tuberculous pleurisy. The cases in Dr. Poulsen's series of tuberculous meningitis were interesting because, as he points out, meningitis is rarely the sole localisation of tuberculosis, miliary disease in the lungs being, as a rule, present also. Out of six cases of meningitis in the series he was able to show that three were excreting tubercle bacilli. From these figures he argues the need for isolation of certain tuberculin-positive children according to their age and condition. All children under 1 year of age with a positive tuberculin reaction he regards as infectious, whether definite physical signs of disease can be found or not. Between 1 and 3 years of age, in most cases, such children are probably non-infectious unless they have meningitis or definite pulmonary localisation; while above this age it is, he thinks, safe for tuberculin-positive children to mix with others, provided neither pulmonary tuberculosis nor pleurisy is present. Even if the need for strict isolation is not generally admitted, Dr. Poulsen has done a useful service in calling attention to a method of obtaining proof of the presence of tubercle bacilli in the sputum of children. His lavage method warrants a trial in this country.

MEDICAL WOMEN AT V.D. CLINICS.

A FEW weeks ago a candidate for a post at a venereal diseases clinic in Scotland was rejected on the ground of sex, as apparently it had been decided that a woman *qua* woman could not hold such a post there. The incident naturally led to some discussion at the Medical Women's Federation, when the council was satisfied of the existence of a definite desire on the part of many women patients to be treated by practitioners of their own sex. In England and Wales, although there is no official ruling to prevent the appointment of women, the number who hold office at V.D. treatment centres seems to be comparatively small. At the close of 1928, according to the report of the chief medical officer of the Ministry of Health, the number of such centres was 188—viz., 178 in England, 10 in Wales. Besides the treatment provided at the regular centres, special arrangements exist at 11 maternity and child welfare centres for the convenience of affected women and children, and besides these there are 14 hostels for the care of girls suffering from venereal diseases and 8 institutions for the reception of pregnant women. Inquiry at the Ministry has elicited the fact that there are 52 women practitioners holding posts at treatment centres, 18 in London and 34 in the provinces. In London there are women medical officers at Guy's, King's, London, South London, Royal Free, and Royal Northern, while in the provinces there are women medical officers at Ashton-under-Lyne, Bradford, Birkenhead, Birmingham, Blackburn, Bolton, Hull, Leeds, Leicester, Lincoln, Liverpool, Newcastle-on-Tyne, Nottingham, Oxford, Plymouth, Preston, St. Helens, Southampton, Southend-on-Sea, Stroud, Sunderland, Waddon, and York. The Federation is not satisfied with this position and has passed a resolution urging that medical officers treating female venereal disease cases whether in hospitals or clinics should be women practitioners where and whenever such practitioners are available. There is cumulative evidence that the clinics serve their purpose more fully where this is the case; at the Royal Free clinic the medical officers see many of the most dangerous type of prostitute and their ability to get these women into hostels must prevent a large amount of infection. It may be that there are not at the moment enough women with sufficient experience to warrant appointment to such clinics, but if the demand was present there is little doubt that this defect would soon be remedied.

THE Nobel Prize for Chemistry for 1929 has been divided between Prof. Arthur Harden, D.Sc., F.R.S., and Prof. Hans von Euler. Dr. Harden is head of the Biochemical Department at the Lister Institute and Professor of Biochemistry in the University of London. Prof. von Euler holds the chair of organic chemistry in the University of Stockholm and is well known for his work on enzymes and vitamins.

ON Wednesday, Nov. 27th, the Duchess of Atholl will lay the foundation-stone of the new London Clinic and Nursing Home at the top of Harley-street. The ceremony will take place at noon at the Devonshire-place entrance to the Clinic, and will be followed by a luncheon at 1 P.M. at the Trocadero Restaurant, Piccadilly.

HEALTH EXHIBITION IN LONDON.—Lord Askwith will open the New Health Society's second annual exhibition at 3 P.M. to-day, Friday, Nov. 15th, at the Royal Horticultural Hall, Westminster. The exhibition will be open daily from noon to 10 P.M. until Nov. 22nd.

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

LII.

THE DIAGNOSIS OF ACUTE FOOD POISONING.

PART I.*—CAUSATION AND CLINICAL PROBLEMS.

A STUDENT of medical evidence given at inquests on deaths from food poisoning acquires the impression that the knowledge of this subject possessed by many practitioners lags behind the scientific data available. The more specialised bacteriological and public health aspects of food poisoning are of interest mainly to experts in these subjects, and only those clinical and pathological problems which present themselves to the medical practitioner need be discussed here.

A difficulty which occurs at the outset is that of defining what we mean by "acute food poisoning." The term itself is inaccurate, because in many cases we are dealing with food infections, the poisons being manufactured subsequently to ingestion. Yet if we adopt instead the term food infections we exclude definite types and must include such infectious diseases as enteric fever, paratyphoid fever, dysentery, and cholera. These are not generally understood by the expression acute food poisoning, and the term is reserved for acute illness caused by food, due either to introduced chemical substances, toxic bacterial products in the food, or to the ingestion of bacteria which produce in the alimentary tract products causing acute illness. This clearly is not a watertight definition, but covers generally what is meant by food poisoning and excludes the ordinary bacterial infectious diseases.

Causation.

In order to appreciate the significance of the presence or absence of certain bacteria in the specimens examined it is necessary to bear in mind what agents have been incriminated in cases of food poisoning. A convenient classification is based upon the nature of the irritant, and the following varieties may be recognised.

1. Food may be contaminated with comparatively simple chemical substances not of bacterial origin. These include simple chemical poisons like zinc, arsenic, and copper salts, and rather more complex bodies such as the alkaloids. These may gain access to the food by accidents of manufacture such as the use of arsenic contaminated glucose in beer or sweets, by carelessness of usage as when acid foods are cooked in zinc or copper receptacles, or by criminal addition.

2. Poisoning may result from the consumption of foods inherently poisonous or which become poisonous under certain conditions. Mushroom poisoning is the best-known example of this type, but poisonous berries and the tropical poisonous fish are others. Mussel poisoning, according to the latest investigations, is in the class of foods normally sound which, under certain ill-defined conditions in the life of the mussel, become toxic. Cases of mussel poisoning are rare. but a widespread outbreak has recently occurred with mussels obtained from California waters. In all this group the symptoms are due to chemical poisons of highly complex type.

3. The toxic action of certain bacteria may cause poisoning. Three groups are well defined.

(*a*) *B. botulinus.*—This bacillus in its three types causes the peculiar and *rare* condition known as *botulism.*

(*b*) *Salmonella bacilli.*—Members of this group give rise to the commonest and most important variety of food poisoning. This group includes many types, and not all the members can originate food poisoning. Those most frequently found as a cause of this condition are *B. aertrycke* and *B. enteritidis*, but some half dozen other types may also be concerned. Another well-known member of this group, *B. paratyphosus* B, causes paratyphoid fever but never, or at the most extremely rarely, can cause acute food poisoning. These Salmonella bacilli produce toxins which are highly irritant, while they possess the peculiar property of being heat resistant—i.e., they withstand temperatures of 100° C. and above without impairment of their toxicity. In consequence of this property we can recognise two types of poisoning from their action. In the one the food is consumed containing living Salmonella bacilli, with or without much pre-formed toxin. In the other type the food after preparation has been subject to heat treatment. killing living Salmonella bacilli (which have low heat resistance) but leaving unimpaired their pre-formed toxins. The food is sterile, unaltered in appearance, but highly toxic. Outbreaks of this character are most common in connexion with certain canned foods, mainly canned meat, the heat preparation processes killing the living bacilli. It must here be stated that this conception of the origin of the toxins, which represents my own views and experience, is not universally accepted, especially in America. The arguments in its favour and against it were set out at the discussion [1] held at the last meeting of the British Medical Association (Section of Pathology). Of the frequency of these canned food outbreaks associated with a sound, sterile food there is no question; I have investigated, or have notes of dozens of them.

(*c*) *Dysentery bacilli.*—A few outbreaks are caused by strains of this group. The clinical picture is identical with that caused by Salmonella strains, and they require no further mention.

4. Indeterminate bacteria or their products. While detailed studies assign a larger and larger share of food poisoning outbreaks to the known types mentioned above, and particularly to the Salmonella group, there remains a residuum of possibly 25 to 30 per cent. which are at present unexplainable. No doubt other bacteria will be found to be responsible while irritation almost amounting to food poisoning may be associated with many ill-defined substances.

Certain Factors Excluded.

On the other hand it is possible to exclude certain factors popularly accepted as causes of food poisoning. There is no evidence of any value that putrefactive changes in meat or other foods has ever caused an outbreak of food poisoning, although it is probable that the consumption of incipiently putrefactive food might disagree with individuals and cause symptoms of malaise. *B. proteus*, a highly putrefactive bacillus, has often been credited as the cause of food poisoning outbreaks, but in nearly all the instances the so-called evidence is worthless. It is a possibility, however, that strains of special virulence might cause food poisoning, and this bacillus cannot be entirely excluded.

As regards *ptomaines*, these are non-specific toxic bodies produced in any organic matter allowed to putrefy if the processes are allowed to go on long enough. They are late protein degradation products, never found in food until it is far too nasty to eat. They certainly have nothing to do with food poisoning, and the term "ptomaine poisoning" should be relegated to the limbo reserved for unfounded hypotheses. It is not creditable to medical practice that the term is still so frequently met with, even in text-books.

Clinical Problems.

Food poisoning being so ill-defined a condition it is evident that in some cases doubt must arise as to its diagnosis. Obviously, with a chemical agent the symptoms must vary with the nature of the chemical poison, which is sometimes highly unexpected. For instance, atropine poisoning has resulted from eating meat stuffed with herbs containing belladonna leaves. Most of these *chemical poisons* cause gastro-intestinal irritation, but usually have a shorter incubation period than the poisons of bacterial origin. *Botulism* has a quite peculiar symptomatology since the toxins act on the nervous system and not on the alimentary tract. Except as a transient initial phase diarrhœa and vomiting are absent, indeed constipation is usual. The characteristic symptoms are visual and eye disturbances, throat symptoms, and general muscular weakness; the temperature is generally subnormal. This type has the longest incubation period (18–36 hours as an average). In *Salmonella food poisoning* the brunt of the attack is on the alimentary tract, and acute diarrhœa, severe vomiting, and abdominal pain are almost invariably present, other less prominent symptoms being a rise in temperature, cramps, and subsequent prostration. When living bacilli are ingested the incubation period is often eight hours or longer. The type due to *Salmonella toxins* without living bacilli presents a very definite clinical picture. The incubation period is quite short (2–4 hours), the onset always acute. These gastro-intestinal symptoms are usually severe in type, more so than with living Salmonella bacilli, and are followed almost always by rapid recovery (24 hours or so), the only deaths being in the old, the very young, or those damaged by concurrent disease.

---

* Part II., on Laboratory Investigations, will appear next week.

[1] See THE LANCET, August 10th, p. 279.

A suspicion of food poisoning may be easy or difficult to confirm. Diagnosis is easy when a number of persons in one household are affected with acute gastro-intestinal disturbance some time after eating a particular meal. The fact that some escape an attack, even if they all consume the same food, does not of necessity invalidate a food hypothesis. In many outbreaks some who have eaten the poisonous food escape. More complex and difficult of diagnosis is the occurrence of a number of cases exhibiting gastro-intestinal irritation symptoms, but irregularly distributed as regards time of occurrence, and not following or not definitely attributable to any particular meal or article of food eaten. Sometimes very detailed inquiry is necessary before it can be shown that some article is infected but perhaps eaten in the family under different conditions—i.e., cooked, stored, &c. A diagnosis has sometimes to be made from influenza of gastro-intestinal type.

A diagnosis of food poisoning may be difficult when a single case is involved. A person, for example, consumes a meal possibly containing articles often associated with food poisoning, and some hours subsequently is taken ill with diarrhœa and vomiting. The sufferer ascribes it to the food, and may then recollect, or more often thinks he recollects, that he noted something "not quite right" about it. Great caution has to be exercised before accepting such an association as one of cause and effect, and all other possible causation factors need to be considered. On several occasions I have known acute peritonitis from a perforated ulcer or other cause diagnosed as food poisoning. Very detailed inquiries should be made as to whether the suspected food was also eaten by other persons, and if they consumed it without harm. It is unlikely that a food consumed by several persons should make only one of them violently ill. An exceptional case is when the whole of one article is consumed by the sufferer, and then laboratory diagnosis is most valuable. For example, I investigated a single case of acute food poisoning caused by the consumption of a Cornish pasty on a railway station, proof being furnished by bacteriological investigation. Many of the single cases of botulism reported in U.S.A. have an interesting explanation. The person preparing the food, usually home-canned vegetables, notices a peculiar smell and tastes a few drops of the liquor; then recognising it is unsound she throws the rest away. The taster thus furnishes the only case.

WILLIAM G. SAVAGE, B.Sc., M.D. Lond.,
Medical Officer of Health for the County of Somerset.

MEDICINE AND THE LAW.

Criminal Lunatics at Large.

THE Home Secretary was asked last week about the escape from Devizes Mental Hospital of a patient who had been transferred thither a year ago from Broadmoor Criminal Lunatic Asylum. He replied that the Home Office is not officially notified of such an escape; the patient, while under sentences for larceny and false pretences, was certified insane and removed to Broadmoor; when his sentence expired in October, 1928, he ceased to be a criminal lunatic, but, being still insane, was recertified under the ordinary lunacy law and received into the Devizes Hospital. The reference to the ordinary law seems to be to Section 7 of the Criminal Lunatics Act, 1884. When a criminal lunatic is about to be "absolutely discharged" (under Section 5 of the Act) or when his sentence is about to determine, then, if the fact is made to appear to a justice of the peace by notice from the superintendent of the asylum or the governor of the prison, and if "in the opinion of such superintendent or governor such person is insane and unfit to be at large," the justice is to examine the person and make inquiry with the aid of medical evidence and to order his detention as a lunatic if satisfied that the person is insane and ought to be detained under care and treatment.

It does not appear that criminal lunatics are let loose upon the public in large numbers or without adequate discrimination. The Criminal Statistics for 1927 (the last available) show that, of 10 inmates of Broadmoor whose sentences expired in the year under review, only 2 were set at large, the other 8 being ordered by a justice to be removed elsewhere. In the same period 14 were discharged conditionally and 3 cases were readmitted on revocation of conditional discharge. The corresponding figures for the county, county borough and district asylums are as follows:—56 persons were discharged absolutely on the expiration of their sentences; of these only 4 were set at large, one was ordered to be removed elsewhere, and 51 were ordered by a justice to remain in the asylum. The Broadmoor totals of receptions and discharges of criminal lunatics are roughly the same as those for the local asylums put together. Broadmoor received 66 in 1927 and discharged 59; the other asylums received 71 and discharged 63. The Broadmoor total of discharges, however, includes 33 deaths whereas only 2 deaths are recorded in the figures for the local authorities' asylums.

Passports and Kindness.

A medical practitioner was summoned at the North London Police-court on November 3rd for having unlawfully made untrue statements for the purpose of procuring a passport for two men named in the summons. A third man was summoned for aiding and abetting the offence. One of the preliminary steps towards the issue of a passport is that the applicant should produce a declaration in a printed form verified by a declaration made by a banker, mayor, magistrate, minister of religion, barrister-at-law, physician, surgeon, solicitor or other accepted person of official or professional status. The medical practitioner in the Islington case had signed a declaration stating that he had known the two applicants for two years and could vouch for them as fit and proper persons to receive passports. The truth, according to the representative of the Director of Public Prosecutions, was that the two men had been living for only a couple of days in apartments in Upper Rathbone-place. They mentioned to their landlady's husband that they wanted to obtain passports to go abroad; he took them to his doctor and asked him to sign their applications. The

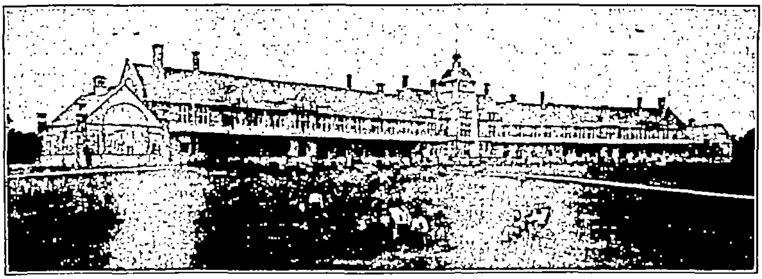
* Part II., on Laboratory Investigations, will appear next week.

[1] See THE LANCET, August 10th, p. 279.

Although the Enabling Act was passed less than six months ago a considerable amount of work has already been carried out, and 150 cases of malignant disease have passed through the hospital. The radium for these cases has been obtained by loan from other hospitals and from private supplies owned by members of the staff. Much more must be available, and, as a beginning, half a gramme has been ordered for the hospital in the form of needles, and the first instalment has recently arrived. In order to carry out the work efficiently on 1500 patients per annum this supply will have to be augmented by 2½ grammes. For X ray treatment at least two sets will be necessary.



The long south frontage, with terrace and balconies.

Follow-up Department.—The results of treatment will be carefully recorded on special forms and diagrams and the patients seen at frequent intervals for years after treatment has ceased. In connexion with the follow-up department notes will be taken down in shorthand of every examination. The existing London section in Fitzroy-square will be the centre for diagnosis and for the follow-up examinations, and it is hoped that the railways may give special facilities of travel to the patients.

Medical Staff.

The members of the honorary medical and surgical staff who are remaining on the staff under the new conditions include Dr. J. F. Halls-Dally, Dr. R. Fielding-Ould, Mr. D. C. L. Fitzwilliams, Mr. C. E Shattock, Mr. P. J. Jory, Mr. H. Robinson, Dr. J. E. A. Lynham, Dr. Percy Hall, Dr. M. Weinbren, and Mr. J. G. Fernie. New appointments include Lady Barrett, Mr. Stanford Cade, Mr. Malcolm Donaldson, and Mr. Geoffrey Keynes.

A near view of the terrace.

The medical and laboratory investigations in the hospital are to be carried out by the staff acting as a *team*. The term of office of each member of the honorary staff is to be for one year only with eligibility for re-election, the term of office being entirely subordinate to the research interests. The members of the staff are not given proprietary rights over a definite number of beds, because it may be advisable from time to time to alter the proportion of admission of patients suffering from any particular type of cancer. The additional members of the medical staff appointed since the reorganisation of the hospital have been chosen from different hospitals because of their interest and experience in the radiological treatment of malignant disease. A whole-time pathologist will be appointed immediately and in the near future a physicist and a whole-time radiologist. It is also part of the original scheme that a medical director shall be appointed to lead the team and coördinate the work. This post would be an important whole-time one with security of tenure for several years.

It is hoped that keen research workers in cancer will gravitate to the hospital from all parts of the Empire. Clinical assistants will be appointed and courses of instruction in radiotherapy will be arranged.

Advisory Committee.

This committee is a new departure in hospital organisation and its duties may be summarised as follows: To advise the Council of Management upon the staffing of the hospital. To advise the Council of Management upon all medical and scientific matters. To suggest the forms of therapy and research which should be undertaken in the hospital.

The present members of this Advisory Committee are Dr. A. E. Barclay, Dr. G. E. Birkett, Dr. R. G. Canti, Prof. C. C. Choyce, Mr. W. D. Harmer, Prof. F. L. Hopwood, Sir Thomas Horder, Prof. E. H. Kettle. Mr. H. S. Souttar, and Sir Charles Gordon Watson, and other members will be coöpted shortly. Half the original members will retire at the end of three years, but in the future members of the Advisory Committee will have a tenure of office for four years, with eligibility for re-election after an interval of one year.

Accommodation and Equipment.

The hospital provides for 150 beds, and this accommodation should give a minimum turnover of 1500 patients per year. The building consists of:—

(a) Fourteen single-bed wards, ten 10-bed wards, two 18-bed wards.

(b) An operating theatre. A new theatre block to contain two complete operating suites is to be built.

(c) An X ray installation for diagnosis, which will be enlarged and brought up to date.

(d) A pathological laboratory. This will be used as temporary accommodation until the new block of research laboratories has been built.

(e) Various rooms and offices for the accommodation of the matron and resident staff.

(f) At either end of the main building are two very large rooms; one of these will be reconstructed to house the deep X ray therapy department, the other will be used for the officers of the follow-up department.

(g) A central hall.

There is a separate nurses' home and a block of buildings containing boilers, electric light plant, laundry, &c. On the west side of the hospital are the foundations of a new wing, which, when completed, will accommodate 100 additional beds, a proportion of which will be reserved for paying patients.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

New Departure in Scottish Research.

A NEW departure of the first importance has taken place in Scotland. A few years ago, when Major Elliot was Under Secretary of State for Scotland, an effort was made to get the official organisation for medical research onto a more satisfactory footing. One of the immediate results of this effort was the well-known experiment—financed by the Empire Marketing Board—on the value of milk as a food for school-children. The organisation established at the time will now be superseded by something much more comprehensive and better adapted to enable the Scottish departments, universities, colleges, and institutes to keep touch with each other and with the local authorities and to make medical and nutritional and related research a continuous accompaniment of administration.

Mr. Tom Johnston, the present Under Secretary of State, recently held a representative conference in Edinburgh. The object of the conference, he explained, was to set up a permanent liaison committee between research bodies and local authorities to see that the results secured by research institutions should be speedily made available to the public.

It is hoped that, at last, Scotland will receive her proportional official share in the work of the Medical Research Council and that the full functional use will be made of the official medical and general scientific staffs of the Departments to investigate the many problems that emerge in the course of health administration. The Departments are to be congratulated on the step taken by Mr. Johnston. The presence of Sir Walter Fletcher's name on the liaison committee, elected at the close of the meeting, indicates that the new development is a natural expansion of the working organisation of the Medical Research Council, of which he is secretary. The other members of the Committee are: Dr. J. P. Kinloch (Chief Medical Officer, Department of Health for Scotland); Dr. J. B. Orr (Director of the Rowett Research Institute, Aberdeen); Sir Robert Greig (Secretary of the Department of Agriculture for Scotland); Prof. T. P. Cathcart (Glasgow University and Hannah Dairy Research Institute); Prof. F. A. E. Crew (Edinburgh University, Animal Breeding Research Department); Dr. T. J. Mackie (Professor of Bacteriology, Edinburgh University); and Mr. John Jeffrey (Secretary of the Department of Health for Scotland). Dr. Kinloch is to be chairman of the Committee.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Irish Free State Medical Registration Council.

THE half-yearly session of the Irish Free State Medical Registration Council was held in the College of Science on Nov. 5th, 1929, the president, Dr. D. J. Coffey, presiding. The president made a statement, in the course of which he pointed out that the privileges of registration—the exclusive right of registered practitioners to give legal certificates, to claim fees in the courts, and to fill public medical appointments—had been in operation since May 20th, 1928. The Council, he said, cordially appreciated the fact that a large number of Irish-trained medical men permanently resident out of Ireland had manifested their interest in the establishment of the Register by taking the necessary steps to include their names.

Death of Dr. Frank Dunne.

Dr. Frank Dunne, of Dublin, died last week after a brief illness. He graduated as M.B. of the Royal University of Ireland in 1891, and was for many years visiting physician to the Consumptive Hospital of the Dublin Union, and also to the Allan A. Ryan Home for Consumptives. He was much interested in the treatment of tuberculosis, and did a considerable amount of work with Denys's tuberculin, which he brought before the notice of the profession in Ireland. During the war he joined the Royal Army Medical Corps, and served in Egypt for some years. He was a careful and observant physician, a man of wide general culture, and of great kindliness of character. His death is greatly regretted by his professional brethren, and also by his large class of sick poor whom he tended with skill and humanity.

Royal Academy of Medicine in Ireland.

The annual report of the Royal Academy of Medicine in Ireland for 1928–29, which was circulated a few days ago, shows a slight increase in the number of Fellows and Members, 258 compared with 245 in the previous session. Twenty-seven national meetings were held, with a total attendance of 1091, the largest number recorded for some years. The section of medicine showed the highest average attendance, the section of obstetrics coming next. The financial statement shows an improvement of a little over one hundred pounds on the year's working. The deaths of five Fellows are recorded—Mr. L. L. Cassidy, Dr. A. J. R. Dungan, Dr. W. A. Fogarty, Prof. T. E. Gordon, and Sir W. J. Thompson. Interesting biographical notices of these are supplied by the general secretary. There are 22 Honorary Fellows on the roll of the Academy.

Libel Action between Medical Men.

In the High Court, Dublin, last week, before Mr. Justice Hanne and a jury, Dr. H. V. McKeogh, of Killaloe, Co. Clare, sued Dr. P. J. Holmes, also of Killaloe, for alleged libel and malicious persecution. Dr. McKeogh had been prosecuted last year on a charge of attempted blackmail on the information of Dr. Holmes, the case ending in acquittal. The alleged libel had been contained in a letter written by Dr. Holmes to a solicitor acting for a third party. The jury found for the plaintiff in respect of both claims, assessing damages at £200 for libel, and £500 for malicious persecution.

The Robert Campbell Oration.

The Robert Campbell Oration for 1929 was delivered in the Medical Institute, Belfast, on Nov. 8th, by Prof. Andrew Fullerton. Mr. Howard Stevenson, President of the Ulster Medical Society, was in the chair, and was supported by Sir Thomas Houston. There was a large audience, widely representative of the medical profession in Ulster, and including Mrs. Robert Campbell and many of the late surgeon's intimate friends. After an eloquent and particularly apt appeciation of the late Mr. Campbell's life and work, the orator reviewed the progress of urology from ancient to modern times, paying a striking tribute to the work of Harry Fenwick in England and H. H. Young in America. An interesting series of lantern slides illustrated the lecture. A vote of thanks was proposed by Prof. Thomas Sinclair, seconded by Dr. James Moore, and carried with enthusiasm.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Congress of German Medical Historians.

THE German Medical History Society held its annual congress this year in Budapest. The occasion was taken to unveil a statue of Semmelweis built in the Elisabeth park in the centre of the city. Foreign speakers gave full recognition to the pious work done by Tibor Györy, professor of medical history at the University of Budapest, in collecting together the works of Semmelweis, and in throwing light on the question of the priority of his famous discovery.

Of the scientific communications to the Congress the most noteworthy was a lecture delivered by Prof. Sudhoff, the president, who described the results of his investigations into medical science as taught at the Arabian Toledo and Salamanca schools, and showed how this knowledge was linked with that developed in the Southern French and Italian universities. Among the other speakers Dr. I. Fischer (Vienna) exhibited a biography of Hippocrates, hand-written by Johannes Cuspinianus (1473–1529); Dr. Else Haberling (Düsseldorf) recalled the early methods of training midwives in Germany; Prof. W. Haberling (Düsseldorf) gave an account of horse riding, as a method of treatment popular in the classic age. Prof. Koch, of Frankfort, urged in his address the closer linking of medical history with medical training; L. Englert read a paper with the title "The Early History of Humoral Pathology"; and O. Temkin (Leipzig), lectured on Celsus and the Roman medical sciences.

In conjunction with the Congress a medico-historical exhibition was arranged by Joseph Ernyei in the Industrial Art Museum.

Articles by Doctors in the Lay Press.

The Press Committee of the Budapest Medical Association, having in mind recent publications on medical subjects in lay journals, warns all doctors that, though it is desirable that scientific instruction on matters of health shall appear in the daily papers, it is objectionable to exploit such articles for advertising purposes. The Ministry of Public Hygiene has shown the way to write such articles, by publishing serial notes dealing with the summer mortality of infants and the prophylactic measures designed to lower it. Caution in publishing scientific articles in the daily papers is advised, because such publications, particularly if the writer gives advice on treatment over his name, may bear the character of an advertisement. The Press Committee investigates all such articles and proposes in the future to deal rigorously with them according to the regulations of the Medical Association. Medical men are invited to submit their articles in the first place to the Press Committee, who will endeavour to place suitable manuscripts in respectable journals.

The Number of Practitioners in Hungary.

According to the latest statistical returns the number of medical practitioners in Hungary amounts to 6142, the ratio to the population being 1 : 1265. Almost half of the doctors reside in Budapest, so that the ratio in this city is 1 : 365, resulting in a keen struggle for existence, whereas there are over 2000 villages without a doctor. The number of medical students at the University of Budapest in the session 1928–29 was 1418, including 90 women, the number of students of pharmacy being only 213. The number of doctors qualifying during the year was 307; this is regarded as far too many, since the demand at present is almost nil.

The Ascertainment of Physical Defectives.

Mr. Eugen Pintér, member of the Chamber of Deputies, has proposed a scheme for the ascertainment of physical defectives, since it is the duty of the State to provide for their treatment and to educate them to be self-supporting, as well as to maintain those incapable of earning a living.

In order to obtain reliable statistics Dr. Michael Horváth, professor of orthopædics, will tour the country, and will give lectures to doctors, magistrates, and interested laymen. When the data have been collected the organisation of training centres will be undertaken. Institutions combining hospitals, schools, and workshops, staffed respectively by surgeons, teachers, and foremen, will have to be provided, but this will take time.

The work cannot be launched simultaneously through the country; Mr. Pintér suggests that the institutions first established should be in the vicinity of the four universities. The State can make a start by ascertainment but the organisation will require moral and material support from the whole community if it is to be a lasting success.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Education and Registration.

THE proposal by Government for a grant of Rs.89,000 for the appointment of an officer of the Indian Medical Service to supervise medical education in India was vigorously opposed in the Assembly at its meeting on Sept. 25th. Discussion was still in progress when the House adjourned and the proposal is shelved until the Delhi session. The General Medical Council is bound to insist on a certain standard of proficiency before granting recognition of degrees granted in India—or anywhere else for that matter; if India consistently refuses to attain to this standard her degrees will, we fear, go unrecognised.

The Congress Party intends, we understand, to introduce in the next session of the Bengal Legislative Council a Bill to amend the Bengal Medical Act No. 6 of 1914 so as to "vest the Bengal Council of Medical Registration with wider powers and free it from Government control." One of the most important clauses in the proposed Bill aims at controlling the State Medical Faculty, the governing body of which is at present nominated entirely by Government.

A New Disease in Bombay.

Sixteen cases of a peculiar disease, the intimate nature of which has not yet been discovered, have appeared in Bombay since April last. Of these seven have proved fatal, and St. George's Hospital was closed for 11 days in September to allow of complete disinfection following the treatment of the cases. Subsequent events seem to have ruled out the possibility, suggested a few months ago, that we are dealing with examples of Dukes's "fourth disease," and opinion appears to be veering in the direction of a streptococcal infection similar in type to malignant scarlet fever. Research into the ætiology is in progress at the Haffkine Institute, Parel, but no definite conclusions have as yet been reached.

The Simla Municipality, at its meeting on Sept. 27th, discussed the question of medical inspection of passengers entering Simla, as a precautionary measure against the importation of infectious diseases. After a lengthy debate the committee decided to ask the

Punjab Government to set up permanent accommodation for a medical inspection staff at Tara Devi.

After a stormy career, Mr. Sarda's Child Marriage Bill, designed to prohibit the marriage of girls below the age of 14, was passed by the Assembly on Sept. 23rd by 67 votes to 14. Despite the fact that eight Moslem members protested against the Bill by walking out of the Chamber it is recognised on all sides that the measure is one of the greatest national importance.

Public Health Services.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Average elementary school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.†
Taunton ..	2784	2592	964	2571	16·0
Torquay ..	3841	3336	1264	5191	20·1
Dover.. ..	—*	5371	2028	3999	8·8
County of Cambridge	9770	8580	3573	6455	7·7

* Not given. † Excluding dental defects and uncleanliness.

Taunton.

THE borough has two features which, in some respects, tend to facilitate the work of caring for the children. It is the administrative centre for Somerset, and therefore use can be made of facilities provided by the county council; the county orthopædic clinic, for instance, is held in the school clinic at Taunton and is available for the infants and the school-children of the borough. A similar arrangement holds at the tuberculosis dispensary. Both the orthopædic and antituberculosis work are greatly aided by voluntary local agencies. Coördination of all the health services is complete, since Dr. John Allen combines the duties of medical officer of health and school medical officer, besides directing the work of the maternity and child welfare scheme. He deals with children employed in entertainments, and cites as examples of the need for careful supervision over these children, that one of their "matrons" considered it not unreasonable for these children to sleep in one bed, and another thought there was no objection to a boy of 14 sleeping in the same room as adult females. The small number of exceptional children makes it more difficult to provide special schools, and consequently there is none. Dr. Allen says there are 32 feeble-minded children attending ordinary schools where "they can obtain little or no benefit from the education provided," and that it would be greatly to their advantage if special classes could be arranged in two schools, with education suitable to their capacities. There would also seem to be a need for the provision of an open-air school as there are 34 "delicate" children and several others who could well attend these. At some other towns with but little larger numbers of children the open-air school is doing excellent work.

Torquay.

In his introduction to the detailed report on school medical work Dr. T. Dunlop remarks that the personnel of the staff is the same as in 1926–27, and that such continuity of service tends to greater efficiency in the work. Dr. J. V. A. Simpson has carried on the school duties for a succession of years and is also in charge of the maternity and child welfare centre, so that he sees the same individual as a baby, a school entrant, and as an older child about to leave school. Such continuity, in the double sense, is of special value in promoting what he obviously has at heart, the *steady inculcation of habits of health.* If, in the words of Matthew Arnold, "Education is an atmosphere, a discipline, a life," Dr. Simpson holds that the part which the school medical service plays in it "may be small, but it is important." The qualifying phrase seems to us unduly modest; this service is of immense importance, its greatest value lying not in its curative work, but in the education in hygiene which it carries out in coöperation with the teachers. Dr. Simpson himself admits this when he remarks that mothers get to appreciate the early signs of defect and come to the welfare centre because the elder brother or sister at school has been successfully treated. Again, when congratulating the authority on improvements in the hygiene of school buildings (largely as the result of his long and painstaking researches with the kata-thermometer), he emphasises its far-reaching significance, for not only does it react sharply on the health of the individual, but it is in itself an education for the pupils—a knowledge which will be applied later in their own homes. He is still more emphatic about the true use of an open-air school, which is to teach the child how to keep well by the observance and practice of a healthy way of life. It needs, he is satisfied, something more than a casual effort to ensure that a child has in all respects a sound general upbringing, but it is within the scope of human achievement.

Dover.

In his introduction Dr. A. B. McMaster says the publication, sanctioned by his committee, of the school report in one volume with that of the public health gives greater facilities for comparing the various sections of the work. The range of this work is especially wide in Dover, which is a town with the usual schools, a seaside resort, and a port with a military quarter. The maternity and child welfare work is being further developed, greater use being made of the beds provided at the Royal Victoria Hospital; the rate of maternal mortality is only 2·6 per 1000 this year. At the welfare centre 442 children were treated, and it is noteworthy that of 24 infants with ophthalmia, all retained unimpaired vision. The approval of the Ministry has been obtained for a scheme for orthopædic treatment of children under five, which will in time reduce the number to be dealt with at school age. The need for early treatment generally is illustrated by an analysis of 30 cases of convergent squint, which shows that in 14 the vision of the affected eye had become 6/60 or worse. Much useful work on refractive errors was again done at the ophthalmic clinic, when glasses were prescribed for 94 per cent. of those who attended, and of these 84 per cent. obtained them. Dental conditions appear to be generally good; attendance increased and extractions of permanent teeth diminished, while 38 per cent. of the children have sound teeth. "There is, unfortunately," writes Mr. F. Constant, L.D.S., "a small percentage of children with septic mouths, whose parents refuse year after year, despite appeals and interviews, to allow to be treated. To save these children suffering and perhaps permanent ill-health, it is a question whether some judicious pressure should not be brought to bear in the more serious of these cases." Dr. McMaster has used his influence against expenditure on a water-softening scheme, which as he shows is not necessary for health, and money is wisely being spent in other directions, such as the new school in Astor Avenue, which in many ways comes near to the ideal.

County of Cambridge.

Dr. F. Robinson's area is entirely rural in character, and this feature affects result sand methods in many directions. In rural areas the child population tends to be less physically defective than that in many of the towns, while ascertainment is carried out with greater difficulty; it is therefore not surprising that the percentage of defects found is much below the average for England as a whole. The travelling dental clinic, adopted early in this county, appears to be yielding good results; for example, the proportion of children found to need dental treatment in 1928 was only 40 per cent., compared with 65 per cent. in 1914. The percentage was even lower in 1922, and Mr. J. C. Evered, L.D.S., suggests an interesting explanation. The greatest crop of dental cases occurs at 7, so it would be especially the children born in 1915 who would affect the figures. Now whereas in central European countries the nutrition of the children suffered severely at that time, the opposite was the case in this country, perhaps on account of high wages and separation allowances. Hence it may be that better nutrition in infancy produced teeth more resistant to decay. In 1928 the percentage of refusals was lower by 1·7 per cent. than last year, an improvement to be attributed largely to the enlightenment of the parents, for which special efforts have been made at the welfare centre and the women's institute, good use being made of cinema films. In this type of area it is not surprising that the establishment of an orthopædic scheme will need an orthopædic surgeon to visit several local centres in turn, and an orthopædic nurse to travel about constantly. In country districts the new grouping of schools makes the provision of meals specially important, and a good account is given of plans to cope with the difficulty; special mention is made of what is done at the Bassingbourn Council School, where a good dinner is provided at a cost of 2½*d.* A few children whose nutritional state is so bad as to prejudice their education are sent to residential open-air schools. Owing to the scattered nature of the district no special nursery schools have been established. There has been a striking improvement in cleanliness, very satisfactory for a rural area; only 4 per cent. of the school-children were found to be not clean. There should, says Dr. Robinson, be a still further reduction in future years, as the girls grow to the age of motherhood who have become familiar with the problem through the scheme of school medical inspection. The same thought for coördination and continuity is evident in the lectures to mothers and in the extension of treatment of squint to the infants under the care of the health visitors.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 2ND, 1929.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 168 (last week 131); scarlet fever, 3487; diphtheria, 1748; enteric fever, 83; pneumonia, 979; puerperal fever, 42; puerperal pyrexia, 96; cerebro-spinal fever, 4; acute poliomyelitis, 20; acute polio-encephalitis, 4; encephalitis lethargica, 15; dysentery, 7; ophthalmia neonatorum, 108. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Nov. 5th–6th was as follows:—Small-pox, 178 under treatment, 8 under observation (last week 172 and 12 respectively); scarlet fever, 2763; diphtheria, 2587; enteric fever, 97; measles, 271; whooping-cough, 121; puerperal fever, 25 (plus 16 babies); encephalitis lethargica, 124; poliomyelitis, 9; "other diseases," 23. At St. Margaret's Hospital there were 12 babies (plus 8 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 7 (1) from enteric fever, 20 (4) from measles, 7 (0) from scarlet fever, 15 (1) from whooping-cough, 39 (6) from diphtheria, 102 (30) from diarrhœa and enteritis under two years, and 40 (9) from influenza. The figures in parentheses are those for London itself.

The deaths from enteric fever outside London were reported from Wood Green, West Bromwich, Grimsby, Wigan, Doncaster, and Newcastle-on-Tyne, 1 each. Liverpool still reports 11 deaths from diarrhœa, Manchester 8, Birmingham and Hull 5 each.

The number of stillbirths notified during the week was 252 (corresponding to a rate of 39 per 1000 births), including 38 in London.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. J. Hamilton to be Surg. Lt.-Comdr.

The following appointments have been made:—Surg. Comdrs. W. W. D. Chilcott to *Emperor of India;* H. B. Parker to *Hawkins;* W. C. Carson to *Vulcan;* J. M. Horan to *Delhi;* M. S. Moore to *Lucia;* and G. B. Cockrem to *Vivid,* for R.N. Barracks, Devonport. Surg. Lt.-Comdr. (D.) R. J. M. Andrews to *Vivid,* for R.N. Barracks, Devonport. Surg. Lts.; C. Keating to *President,* for three months' post-graduate course; R. C. Foster to *Vivid,* for R.N. Hospital, Plymouth; R. H. Dummett to *Vivid,* for R.N. Barracks, Devonport; and J. B. Douglas to *Hawkins.*

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lt. W. Greaves to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Capts. to be Majs.: Bt. Maj. R. E. Barnsley, J. R. N. Warburton (and remains secd.), W. L. E. Reynolds, A. Mearns, A. E. Richmond, and T. B. H. Tabuteau.

TERRITORIAL FORCE.

Maj. T. H. Oliver resigns his commn.

Capt. O. G. Misquith to comd. 7th (Southern) Hygiene Co.

Capt. E. H. Mayhew, having attained the age limit, relinquishes his commn. and retains his rank.

Lts. J. Kerr and E. R. C. Walker to be Capts.

E. M. R. Frazer (late Offr. Cadet, Edinburgh Univ. Contgt., Sen. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE.

W. S. Stalker is granted a temporary commission as a Flight Lt.

Flying Offrs. Leo O'Connor, A. L. St. A. McClosky, and Ronald Thorpe are promoted to the rank of Flight Lts.

Flight Lt. (Acting Squadron Leader, Hon. Wing Commander) J. N. MacDonald is promoted to the acting rank of Wing Commander, with pay, whilst so employed.

Flying Offr. E. A. Wilson relinquishes his short service commission on account of ill-health.

Flying Offr. V. G. Pedley (Temp. Lt., General List, Army, Dental Surgeon) relinquishes his temporary commission in the R.A.F. on completion of service.

INDIAN MEDICAL SERVICE.

Lt. Thaku Chuharmal Ramchandani to be Capt. (prov.).

Lt.-Col. J. Forrest retires.

The undermentioned relinquish their temp. commns.: Temp. Capts. Hari Krishna Datta and Shiv Shanker Gupta, and Temp. Lt. Ellamana Siva Rama Menon.

COLONIAL MEDICAL SERVICES.

The following appointments were made during October: Dr. F. D. Gillespie, Dr. H. Scrimegeour, Dr. J. H. Strahan Dr. T. F. Strong, and Dr. S. N. Swift, Medical Officers, Federated Malay States; Dr. C. E. Hagenbach, Medical Officer, Malayan Medical Service; Dr. W. S. Smith, Medical Officer, Gold Coast; Dr. H. S. R. Broadbent, Medical Officer, Kenya; Dr. A. R. Cox, Medical Officer, Northern Rhodesia; Dr. Peaston, Medical Officer, Sierra Leone; Dr. D. Russell, Assistant Medical Superintendent, Mental Hospital, Singapore; Dr. J. J. Black, Dr. R. L. Hyder, and Dr. G. A. T. Jones, Medical Officers, Uganda; and Dr. R. Ramsay and Dr. P. B. Wilkinson, Medical Officers on the West African Medical Staff.

PRESENTATION TO A MEDICAL MAN.—Dr. Robert Fell, who has been the senior anæsthetist at the York County Hospital for 30 years and who has lately retired from the active staff, was entertained at dinner last week by his colleagues. Dr. W. A. Evelyn, senior physician to the hospital, was in the chair, and after dinner Dr. Fell was presented with a silver salver.

Correspondence.

"Audi alteram partem."

THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—Voting papers in connexion with the election of Direct Representatives are being issued on Thursday, the 14th inst., to all practitioners having registered addresses in England and Wales. Any such practitioner who does not receive a voting paper, whether he wishes to vote in the election *or not*, should immediately communicate with the office in order to ascertain that his address is correctly entered in the Register.

I am, Sir, yours faithfully,
NORMAN C. KING,
Registrar, General Council of Medical Education and Registration of the United Kingdom.
44, Hallam-street, Portland-place, London, W., Nov. 12th, 1929.

VACCINATION OR INOCULATION AGAINST SMALL-POX?

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 2nd Dr. H. T. Gillett asks whether any experiments are being done on the production of immunity by killed vaccinia virus. In the same issue Dr. S. P. Bedson points out that I am conducting an investigation here into this question. This work has the approval and assistance of the Ministry of Health. My research is, at present, in its earliest experimental stage and few conclusions can be drawn from it. The majority of the experiments have been done on rabbits and have proved very discouraging but, recently, experiments with guinea-pigs have given more hopeful results. These findings are in accord with those of Iwanoff who also found guinea-pigs easier to immunise than rabbits.

With reference to your editorial comment upon Dr. Gillett's letter I cannot see that, should a method ever be evolved for protecting man against variola with killed virus, this would require a stock of real small-pox virus. The viruses of vaccinia and small-pox are immunologically identical and mutually protective, and the killed vaccine would be made from the former virus just as is the living vaccine in present use.

I would add to your list of virus infections from which a killed vaccine confers immunity yellow fever, against which both formolised and phenolised viruses are effective, and fowl-pox from which even a heat-killed virus provides immunity. The length of your list reinforced by my additions strongly suggests that the production of immunity by killed vaccinia virus only awaits the discovery of the correct technique.—I am, Sir, yours faithfully,

JOHN BLAND,
Freedom Research Fellow.
Hale Clinical Laboratory, London Hospital, E., Nov. 7th, 1929.

To the Editor of THE LANCET.

SIR,—The suggestive and valuable Observations on Vaccination by Dr. Bedson, and the letter from Dr. Gillett, both of which appeared in your issue of Nov. 2nd. indicate the need for the elaboration of a method of vaccination which will be devoid of the inconvenience unavoidably associated with the technique so far employed. At present we are engaged in an investigation of the question raised by Dr. Gillett—viz., the (possible) production of immunity against small-pox by inoculation of killed vaccinia virus. This work is being conducted on behalf of the Medical Research Council and is a natural corollary of our observations already published in Special Report Series No. 143 of that body.

The necessary preliminary to the production of immunity against small-pox is that it must be shown that the immunisation by vaccinia virus which has been rendered innocuous will protect against living vaccinia virus, and in this we have met with considerable success. One point must be stressed—namely, that if a living virus is used for immunising, only a small dose may be required, the immunity really being developed by reproduction in the tissues of the virus inoculated, whereas with a dead virus very much larger doses may be necessary. It is not possible to standardise a living virus unless in terms of infectivity for some laboratory animal—always an uncertain method—while it is not difficult to standardise, in the physical sense at least, the dose of the killed virus; on the other hand, such physical standardisation must be correlated with physiological activity.

Our observations are not yet sufficiently numerous to permit of a definite statement being made, but the indications so far obtained from our work are that a living virus, after modification in vitro without the employment of either antiseptics or heat, may fulfil the required conditions, these conditions being adequate protection unaccompanied by untoward local reactions or danger of post-vaccinal sequelæ.

We are, Sir, yours faithfully,
W. J. TULLOCH.
J. CRAIGIE.
Bacteriological Department, University College, Dundee, Nov. 5th, 1929.

THE CRAFT OF SURGERY.

To the Editor of THE LANCET.

SIR,—Though I have left the profession I have not lost my interest in medicine, and my experience in the war certainly increased this interest; I hope, therefore, I shall not be considered presumptuous if I say something about surgery, considered as a craft, and even make some suggestions. Surgery is a craft, a very skilled craft, requiring much natural ability and practice in its leaders, the surgeon being the principal craftsman in the medical profession, who is called on to act, when action is considered necessary. That he is much more than a craftsman hardly needs stating. The uses of surgery are increasing every day, and good surgeons are required all over the Empire; and no medical man out of touch with a large town can ever be exempt from being called on to operate; it is becoming more and more important that every medical student should be trained in the craft of his profession.

Is this craft constantly and systematically taught, for it certainly was not in my day? The surgeon's craft, owing to the fact that the work is done on living bodies, does not exactly correspond to any other, but it is closely allied to others. The instruments of surgery, though to-day very numerous, largely consist of forms of knives, saws, scissors, forceps, drills, chisels, files, hammers, screw-drivers, and needles and thread. These form in varying forms the tools of other crafts, such as carpentry, stone cutting, leather cutting and sewing, and upholstery. It would not therefore be very difficult to find masters to teach what may be called the fundamental use and upkeep of these tools, the pupil practising upon the various materials. I feel safe in saying that a course of stone cutting, even if it only consisted of lettering under, say, Mr. Eric Gill, the sculptor, would be useful to the future orthopædic surgeon. This constant practice of the hand would give a confidence to the young surgeon, which in my day he had to acquire chiefly on the living body, besides being a great relief from the reading of books. No one can cram up a craft, so that the good man would feel he could not fail in this part of his examination, while the poor craftsman would be told by his instructors that he had no chance. Even in the Final Fellowship Examination in the 'eighties, the test of skill in operating did not keep out the "butter fingers."
